        </ResourceDictionary>
    </Window.Resources>
</Window>
```

Event binding and ICommand

{x:Bind} supports a feature called event binding. With this feature, you can specify the handler for an event using a binding, which is an additional option on top of handling

events with a method on the code-behind file. Let's say you have a `ListViewDoubleTapped` event handler on your `MainWindow` class.

C#

```
public sealed partial class MainWindow : Window
{
    ...
    public void ListViewDoubleTapped()
    {
        // Handle double-tapped logic
    }
}
```

You can then bind a ListView's **DoubleTapped** event to a method on the **MainWindow** like this.

XAML

```
<ListView DoubleTapped="{x:Bind ListViewDoubleTapped}" />
```

Overloaded methods cannot be used to handle an event with this technique. Also, if the method that handles the event has parameters then they must all be assignable from the types of all of the event's parameters, respectively. In this case, `ListViewDoubleTapped` is not overloaded and it has no parameters (but it would still be valid even if it took two `object` parameters).

The event binding technique is similar to implementing and consuming commands (a command is a property that returns an object that implements the **ICommand** interface). Both {x:Bind} and {Binding} work with commands. So that you don't have to implement the command pattern multiple times, you can use the `DelegateCommand` helper class that you'll find in the QuizGame UWP sample (in the "Common" folder).

Binding to a collection of folders or files

You can use the APIs in the **Windows.Storage** namespace to retrieve folder and file data in your packaged Windows App SDK apps. However, the various `GetFilesAsync`, `GetFoldersAsync`, and `GetItemsAsync` methods do not return values that are suitable for binding to list controls. Instead, you must bind to the return values of the **GetVirtualizedFilesVector**, **GetVirtualizedFoldersVector**, and **GetVirtualizedItemsVector** methods of the **FileInformationFactory** class. The following code example from the StorageDataSource and GetVirtualizedFilesVector UWP sample shows the typical

usage pattern. Remember to declare the **picturesLibrary** capability in your app package manifest, and confirm that there are pictures in your Pictures library folder.

C#

```
protected override void OnNavigatedTo(NavigationEventArgs e)
{
    var library = Windows.Storage.KnownFolders.PicturesLibrary;
    var queryOptions = new Windows.Storage.Search.QueryOptions();
    queryOptions.FolderDepth = Windows.Storage.Search.FolderDepth.Deep;
    queryOptions.IndexerOption =
Windows.Storage.Search.IndexerOption.UseIndexerWhenAvailable;

    var fileQuery = library.CreateFileQueryWithOptions(queryOptions);

    var fif = new Windows.Storage.BulkAccess.FileInformationFactory(
        fileQuery,
        Windows.Storage.FileProperties.ThumbnailMode.PicturesView,
        190,
        Windows.Storage.FileProperties.ThumbnailOptions.UseCurrentScale,
        false
        );

    var dataSource = fif.GetVirtualizedFilesVector();
    this.PicturesListView.ItemsSource = dataSource;
}
```

You will typically use this approach to create a read-only view of file and folder info. You can create two-way bindings to the file and folder properties, for example to let users rate a song in a music view. However, any changes are not persisted until you call the appropriate `SavePropertiesAsync` method (for example, MusicProperties.SavePropertiesAsync). You should commit changes when the item loses focus because this triggers a selection reset.

Note that two-way binding using this technique works only with indexed locations, such as **Music**. You can determine whether a location is indexed by calling the FolderInformation.GetIndexedStateAsync method.

Note also that a virtualized vector can return `null` for some items before it populates their value. For example, you should check for `null` before you use the SelectedItem value of a list control bound to a virtualized vector, or use SelectedIndex instead.

Binding to data grouped by a key

If you take a flat collection of items (books, for example, represented by a `BookSku` class) and you group the items by using a common property as a key (the `BookSku.AuthorName`

property, for example) then the result is called grouped data. When you group data, it is no longer a flat collection. Grouped data is a collection of group objects, where each group object has:

- a key, and
- a collection of items whose property matches that key.

To take the books example again, the result of grouping the books by author name results in a collection of author name groups where each group has:

- a key, which is an author name, and
- a collection of the `BookSku` objects whose `AuthorName` property matches the group's key.

In general, to display a collection, you bind the **ItemsSource** of an items control (such as **ListView** or **GridView**) directly to a property that returns a collection. If that's a flat collection of items then you don't need to do anything special. But if it's a collection of group objects (as it is when binding to grouped data) then you need the services of an intermediary object called a **CollectionViewSource** which sits between the items control and the binding source. You bind the `CollectionViewSource` to the property that returns grouped data, and you bind the items control to the `CollectionViewSource`. An extra value-add of a `CollectionViewSource` is that it keeps track of the current item, so you can keep more than one items control in sync by binding them all to the same `CollectionViewSource`. You can also access the current item programmatically through the **ICollectionView.CurrentItem** property of the object returned by the **CollectionViewSource.View** property.

To activate the grouping facility of a **CollectionViewSource**, set **IsSourceGrouped** to `true`. Whether you also need to set the **ItemsPath** property depends on exactly how you author your group objects. There are two ways to author a group object: the "is-a-group" pattern, and the "has-a-group" pattern. In the "is-a-group" pattern, the group object derives from a collection type (for example, `List<T>`), so the group object actually is itself the group of items. With this pattern you do not need to set `ItemsPath`. In the "has-a-group" pattern, the group object has one or more properties of a collection type (such as `List<T>`), so the group "has a" group of items in the form of a property (or several groups of items in the form of several properties). With this pattern you need to set `ItemsPath` to the name of the property that contains the group of items.

The example below illustrates the "has-a-group" pattern. The window class has a property named **DataContext**, which returns an instance of our view model. The **CollectionViewSource** binds to the `Authors` property of the view model (`Authors` is the collection of group objects) and also specifies that it's the `Author.BookSkus` property

that contains the grouped items. Finally, the **GridView** is bound to the `CollectionViewSource`, and has its group style defined so that it can render the items in groups.

XAML

```
<Window.Resources>
    <CollectionViewSource
    x:Name="AuthorHasACollectionOfBookSku"
    Source="{x:Bind ViewModel.Authors}"
    IsSourceGrouped="true"
    ItemsPath="BookSkus"/>
</Window.Resources>
...
<GridView
ItemsSource="{x:Bind AuthorHasACollectionOfBookSku}" ...>
    <GridView.GroupStyle>
        <GroupStyle
            HeaderTemplate="{StaticResource AuthorGroupHeaderTemplateWide}"
... />
    </GridView.GroupStyle>
</GridView>
```

You can implement the "is-a-group" pattern in one of two ways. One way is to author your own group class. Derive the class from `List<T>` (where *T* is the type of the items). For example, `public class Author : List<BookSku>`. The second way is to use a LINQ expression to dynamically create group objects (and a group class) from like property values of the **BookSku** items. This approach—maintaining only a flat list of items and grouping them together on the fly—is typical of an app that accesses data from a cloud service. You get the flexibility to group books by author or by genre (for example) without needing special group classes such as **Author** and **Genre**.

The example below illustrates the "is-a-group" pattern using LINQ. This time we group books by genre, displayed with the genre name in the group headers. This is indicated by the "Key" property path in reference to the group **Key** value.

C#

```
using System.Linq;
...
private IOrderedEnumerable<IGrouping<string, BookSku>> genres;

public IOrderedEnumerable<IGrouping<string, BookSku>> Genres
{
    get
    {
        if (genres == null)
        {
```

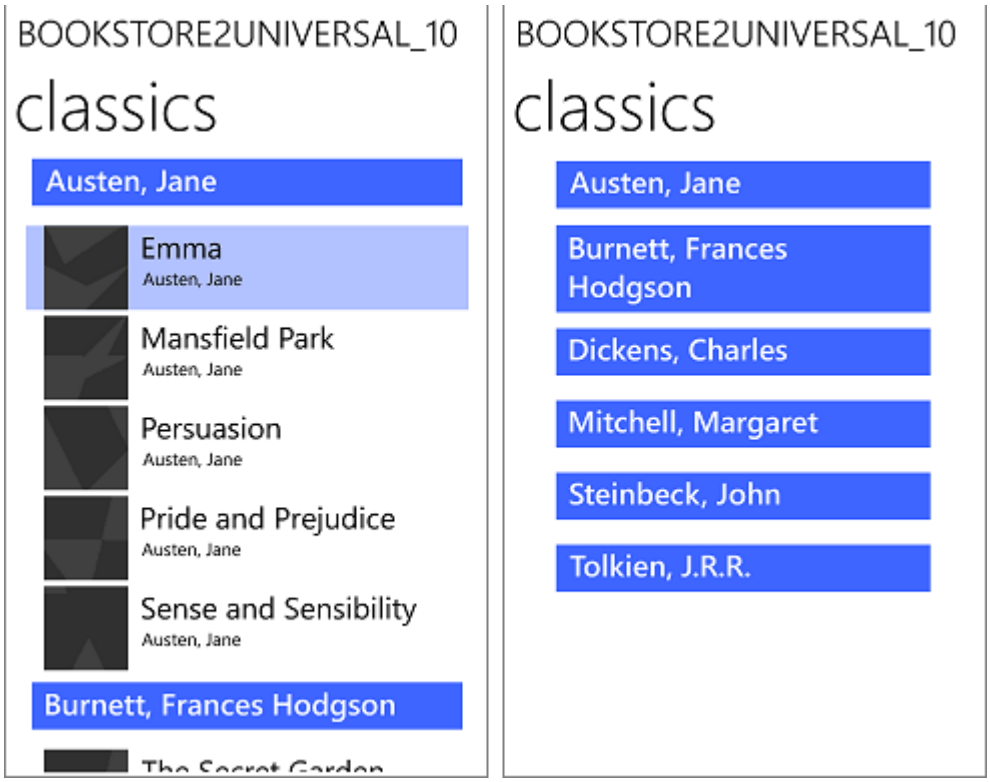
```
            genres = from book in bookSkus
                     group book by book.genre into grp
                     orderby grp.Key
                     select grp;
        }
        return genres;
    }
}
```

Remember that when using {x:Bind} with data templates we need to indicate the type being bound to by setting an `x:DataType` value. If the type is generic then we can't express that in markup so we need to use {Binding} instead in the group style header template.

XAML

```
    <Grid.Resources>
        <CollectionViewSource x:Name="GenreIsACollectionOfBookSku"
        Source="{x:Bind Genres}"
        IsSourceGrouped="true"/>
    </Grid.Resources>
    <GridView ItemsSource="{x:Bind GenreIsACollectionOfBookSku}">
        <GridView.ItemTemplate x:DataType="local:BookTemplate">
            <DataTemplate>
                <TextBlock Text="{x:Bind Title}"/>
            </DataTemplate>
        </GridView.ItemTemplate>
        <GridView.GroupStyle>
            <GroupStyle>
                <GroupStyle.HeaderTemplate>
                    <DataTemplate>
                        <TextBlock Text="{Binding Key}"/>
                    </DataTemplate>
                </GroupStyle.HeaderTemplate>
            </GroupStyle>
        </GridView.GroupStyle>
    </GridView>
```

A **SemanticZoom** control is a great way for your users to view and navigate grouped data. The Bookstore2 UWP sample app illustrates how to use the `SemanticZoom`. In that app, you can view a list of books grouped by author (the zoomed-in view) or you can zoom out to see a jump list of authors (the zoomed-out view). The jump list affords much quicker navigation than scrolling through the list of books. The zoomed-in and zoomed-out views are actually `ListView` or `GridView` controls bound to the same `CollectionViewSource`.



When you bind to hierarchical data—such as subcategories within categories—you can choose to display the hierarchical levels in your UI with a series of items controls. A selection in one items control determines the contents of subsequent items controls. You can keep the lists synchronized by binding each list to its own **CollectionViewSource** and binding the `CollectionViewSource` instances together in a chain. This is called a master/details (or list/details) view. For more info, see How to bind to hierarchical data and create a master/details view.

Diagnosing and debugging data binding problems

Your binding markup contains the names of properties (and, for C#, sometimes fields and methods). So when you rename a property, you'll also need to change any binding that references it. Forgetting to do that leads to a typical example of a data binding bug, and your app either won't compile or won't run correctly.

The binding objects created by {x:Bind} and {Binding} are largely functionally equivalent. But `{x:Bind}` has type information for the binding source, and it generates source code at compile-time. With `{x:Bind}` you get the same kind of problem detection that you get with the rest of your code. That includes compile-time validation of your binding expressions, and debugging by setting breakpoints in the source code generated as the partial class for your page. These classes can be found in the files in your `obj` folder, with names like (for C#) `<view name>.g.cs`). If you have a problem with a binding then turn on **Break On Unhandled Exceptions** in the Microsoft Visual Studio debugger. The

debugger will break execution at that point, and you can then debug what has gone wrong. The code generated by `{x:Bind}` follows the same pattern for each part of the graph of binding source nodes, and you can use the info in the **Call Stack** window to help determine the sequence of calls that led up to the problem.

{Binding} does not have type information for the binding source. But when you run your app with the debugger attached, any binding errors appear in the **Output** and **XAML Binding Failures** windows in Visual Studio. For more information on debugging binding errors in Visual Studio, see XAML data binding diagnostics.

Creating bindings in code

> **Note**
>
> This section only applies to **{Binding}**, because you can't create **{x:Bind}** bindings in code. However, some of the same benefits of `{x:Bind}` can be achieved with **DependencyObject.RegisterPropertyChangedCallback**, which enables you to register for change notifications on any dependency property.

You can also connect UI elements to data using procedural code instead of XAML. To do this, create a new **Binding** object, set the appropriate properties, then call **FrameworkElement.SetBinding** or **BindingOperations.SetBinding**. Creating bindings programmatically is useful when you want to choose the binding property values at run-time or share a single binding among multiple controls. Note, however, that you cannot change the binding property values after you call `SetBinding`.

The following example shows how to implement a binding in code.

XAML

```
<TextBox x:Name="MyTextBox" Text="Text"/>
```

C#

```
// Create an instance of the MyColors class
// that implements INotifyPropertyChanged.
var textcolor = new MyColors();

// Brush1 is set to be a SolidColorBrush with the value Red.
textcolor.Brush1 = new SolidColorBrush(Colors.Red);

// Set the DataContext of the TextBox MyTextBox.
MyTextBox.DataContext = textcolor;
```

```
// Create the binding and associate it with the text box.
var binding = new Binding { Path = new PropertyPath("Brush1") };
MyTextBox.SetBinding(TextBox.ForegroundProperty, binding);
```

{x:Bind} and {Binding} feature comparison

Feature	{x:Bind} vs. {Binding}	Notes
Path is the default property	`{x:Bind a.b.c}` - `{Binding a.b.c}`	
Path property	`{x:Bind Path=a.b.c}` - `{Binding Path=a.b.c}`	In `x:Bind`, `Path` is rooted at the Window by default, not the DataContext.
Indexer	`{x:Bind Groups[2].Title}` - `{Binding Groups[2].Title}`	Binds to the specified item in the collection. Only integer-based indexes are supported.
Attached properties	`{x:Bind Button22.(Grid.Row)}` - `{Binding Button22.(Grid.Row)}`	Attached properties are specified using parentheses. If the property is not declared in a XAML namespace, then prefix it with an xml namespace, which should be mapped to a code namespace at the head of the document.
Casting	`{x:Bind groups[0].(data:SampleDataGroup.Title)}` - Not needed for `{Binding}`.	Casts are specified using parentheses. If the property is not declared in a XAML namespace, then prefix it with an xml namespace, which should be mapped to a code namespace at the head of the document.
Converter	`{x:Bind IsShown, Converter={StaticResource BoolToVisibility}}` - `{Binding IsShown, Converter={StaticResource BoolToVisibility}}`	Converters must be declared at the root of the Window/Control/ResourceDictionary, or in **App.xaml**.
ConverterParameter, ConverterLanguage	`{x:Bind IsShown, Converter={StaticResource BoolToVisibility}, ConverterParameter=One, ConverterLanguage=fr-fr}` -	Converters must be declared at the root of the Window/Control/ResourceDictionary, or in **App.xaml**.

Feature	{x:Bind} vs. {Binding}	Notes
	`{Binding IsShown, Converter={StaticResource BoolToVisibility}, ConverterParameter=One, ConverterLanguage=fr-fr}`	
TargetNullValue	`{x:Bind Name, TargetNullValue=0}` - `{Binding Name, TargetNullValue=0}`	Used when the leaf of the binding expression is null. Use single quotes for a string value.
FallbackValue	`{x:Bind Name, FallbackValue='empty'}` - `{Binding Name, FallbackValue='empty'}`	Used when any part of the path for the binding (except for the leaf) is null.
ElementName	`{x:Bind slider1.Value}` - `{Binding Value, ElementName=slider1}`	With `{x:Bind}` you're binding to a field; `Path` is rooted at the Window by default, so any named element can be accessed via its field.
RelativeSource: Self	`<Rectangle x:Name="rect1" Width="200" Height="{x:Bind rect1.Width}" ... />` - `<Rectangle Width="200" Height="{Binding Width, RelativeSource={RelativeSource Self}}" ... />`	With `{x:Bind}`, name the element and use its name in `Path`.
RelativeSource: TemplatedParent	Not needed for `{x:Bind}` - `{Binding <path>, RelativeSource={RelativeSource TemplatedParent}}`	With `{x:Bind}`, `TargetType` on `ControlTemplate` indicates binding to template parent. For `{Binding}`, regular template binding can be used in control templates for most uses. But use `TemplatedParent` where you need to use a converter, or a two-way binding.
Source	Not needed for `{x:Bind}` - `<ListView ItemsSource="{Binding Orders, Source={StaticResource MyData}}"/>`	For `{x:Bind}` you can directly use the named element, use a property or a static path.
Mode	`{x:Bind Name, Mode=OneWay}` - `{Binding Name, Mode=TwoWay}`	`Mode` can be `OneTime`, `OneWay`, or `TwoWay`. `{x:Bind}` defaults to `OneTime`; `{Binding}` defaults to `OneWay`.

Feature	{x:Bind} vs. {Binding}	Notes
UpdateSourceTrigger	`{x:Bind Name, Mode=TwoWay, UpdateSourceTrigger=PropertyChanged}` - `{Binding UpdateSourceTrigger=PropertyChanged}`	`UpdateSourceTrigger` can be `Default`, `LostFocus`, or `PropertyChanged`. `{x:Bind}` does not support `UpdateSourceTrigger=Explicit`. `{x:Bind}` uses `PropertyChanged` behavior for all cases except `TextBox.Text`, where it uses `LostFocus` behavior.

Functions in x:Bind with Windows App SDK

Article • 06/29/2023

> **Note**
>
> For general info about using data binding in your app with `{x:Bind}` (and for an all-up comparison between `{x:Bind}` and `{Binding}`), see **Data binding in depth** and **{x:Bind} Markup Extension**.

In Windows App SDK apps, **{x:Bind}** supports using a function as the leaf step of the binding path. This enables:

- A simpler way to achieve value conversion
- A way for bindings to depend on more than one parameter

In the following example, the background and foreground of the item are bound to functions to do conversion based on the color parameter

XAML

```
<DataTemplate x:DataType="local:ColorEntry">
    <Grid Background="{x:Bind local:ColorEntry.Brushify(Color),
Mode=OneWay}" Width="240">
        <TextBlock Text="{x:Bind ColorName}" Foreground="{x:Bind
TextColor(Color)}" Margin="10,5" />
    </Grid>
</DataTemplate>
```

C#

```
public class ColorEntry
{
    public string ColorName { get; set; }
    public Color Color { get; set; }

    public static SolidColorBrush Brushify(Color c)
    {
        return new SolidColorBrush(c);
    }

    public SolidColorBrush TextColor(Color c)
    {
        return new SolidColorBrush(((c.R * 0.299 + c.G * 0.587 + c.B *
```

```
0.114) > 150) ? Colors.Black : Colors.White);
    }
}
```

XAML attribute usage

XAML

```
<object property="{x:Bind pathToFunction.FunctionName(functionParameter1,
functionParameter2, ...), bindingProperties}" ... />
```

Path to the function

The path to the function is specified like other property paths and can include dots (.), indexers or casts to locate the function.

Static functions can be specified using `XMLNamespace:ClassName.MethodName` syntax. For example, use the below syntax for binding to static functions in code-behind.

XAML

```
<Window
     xmlns:local="using:MyNamespace">
     ...
    <StackPanel>
        <TextBlock x:Name="BigTextBlock" FontSize="20" Text="Big text" />
        <TextBlock FontSize="{x:Bind
local:MyHelpers.Half(BigTextBlock.FontSize)}"
                   Text="Small text" />
    </StackPanel>
</Window>
```

C#

```
namespace MyNamespace
{
    static public class MyHelpers
    {
        public static double Half(double value) => value / 2.0;
    }
}
```

You can also use system functions directly in markup to accomplish simple scenarios like date formatting, text formatting, text concatenations, etc. For example:

XAML

```
<Window
     xmlns:sys="using:System"
     xmlns:local="using:MyNamespace">
     ...
     <CalendarDatePicker Date="{x:Bind sys:DateTime.Parse(TextBlock1.Text)}"
/>
     <TextBlock Text="{x:Bind sys:String.Format('{0} is now available in
{1}', local:MyPage.personName, local:MyPage.location)}" />
</Window>
```

If the mode is OneWay/TwoWay, then the function path will have change detection performed on it, and the binding will be re-evaluated if there are changes to those objects.

The function being bound to needs to:

- Be accessible to the code and metadata – so internal / private work in C#, but C++ will need methods to be public WinRT methods
- Overloading is based on the number of arguments, not type, and it will try to match to the first overload with that many arguments
- The argument types need to match the data being passed in – we don't do narrowing conversions
- The return type of the function needs to match the type of the property that is using the binding

The binding engine reacts to property change notifications fired with the function name and re-evaluate bindings as necessary. For example:

XAML

```
<DataTemplate x:DataType="local:Person">
   <StackPanel>
      <TextBlock Text="{x:Bind FullName}" />
      <Image Source="{x:Bind IconToBitmap(Icon, CancellationToken),
Mode=OneWay}" />
   </StackPanel>
</DataTemplate>
```

C#

```
public class Person : INotifyPropertyChanged
{
    //Implementation for an Icon property and a CancellationToken property
with PropertyChanged notifications
    ...
```

```
    //IconToBitmap function is essentially a multi binding converter between
several options.
    public Uri IconToBitmap (Uri icon, Uri cancellationToken)
    {
        var foo = new Uri(...);
        if (isCancelled)
        {
            foo = cancellationToken;
        }
        else
        {
            if (fullName.Contains("Sr"))
            {
               //pass a different Uri back
               foo = new Uri(...);
            }
            else
            {
                foo = icon;
            }
        }
        return foo;
    }

    //Ensure FullName property handles change notification on itself as well
as IconToBitmap since the function uses it
    public string FullName
    {
        get { return fullName; }
        set
        {
            fullName = value;
            OnPropertyChanged();
            OnPropertyChanged("IconToBitmap");
            //this ensures Image.Source binding re-evaluates when FullName
changes in addition to Icon and CancellationToken
        }
    }
}
```

> **Tip**
>
> You can use functions in `x:Bind` to achieve the same scenarios as what was supported through Converters and MultiBinding in WPF.

Function arguments

Multiple function arguments can be specified, separated by comma's (,)

- Binding Path – Same syntax as if you were binding directly to that object.
  - If the mode is OneWay/TwoWay then change detection will be performed and the binding re-evaluated upon object changes
- Constant string enclosed in quotes – quotes are needed to designate it as a string. Hat (^) can be used to escape quotes in strings
- Constant Number - for example -123.456
- Boolean – specified as "x:True" or "x:False"

Two way function bindings

In a two-way binding scenario, a second function must be specified for the reverse direction of the binding. This is done using the `BindBack` binding property. In the below example, the function should take one argument which is the value that needs to be pushed back to the model.

XAML

```
<TextBlock Text="{x:Bind a.MyFunc(b), BindBack=a.MyFunc2, Mode=TwoWay}" />
```

Bind hierarchical data and create a master/details view with Windows App SDK

Article • 06/29/2023

> **Note**
>
> Also see the **Master/detail UWP sample**.

You can make a multi-level master/details (also known as list-details) view of hierarchical data by binding items controls to **CollectionViewSource** instances that are bound together in a chain. In this topic we use the {x:Bind} markup extension where possible, and the more flexible (but less performant) {Binding} markup extension where necessary.

One common structure for Windows App SDK apps is to navigate to different details pages when a user makes a selection in a master list. This is useful when you want to provide a rich visual representation of each item at every level in a hierarchy. Another option is to display multiple levels of data on a single page. This is useful when you want to display a few simple lists that let the user quickly drill down to an item of interest. This topic describes how to implement this interaction. The **CollectionViewSource** instances keep track of the current selection at each hierarchical level.

We'll create a view of a sports team hierarchy that is organized into lists for leagues, divisions, and teams, and includes a team details view. When you select an item from any list, the subsequent views update automatically.

Prerequisites

This topic assumes that you know how to create a basic Windows App SDK app. For instructions on creating your first Windows App SDK app, see Create your first WinUI 3 (Windows App SDK) project.

Create the project

Create a new **Blank App, Packaged (WinUI 3 in Desktop)** project. Name it "MasterDetailsBinding".

Create the data model

Add a new class to your project, name it **ViewModel.cs**, and add this code to it. This will be your binding source class.

C#

```
using System.Collections.Generic;
using System.Linq;

namespace MasterDetailsBinding
{
    public class Team
    {
        public string Name { get; set; }
        public int Wins { get; set; }
```

```
        public int Losses { get; set; }
    }

    public class Division
    {
        public string Name { get; set; }
        public IEnumerable<Team> Teams { get; set; }
    }

    public class League
    {
        public string Name { get; set; }
        public IEnumerable<Division> Divisions { get; set; }
    }

    public class LeagueList : List<League>
    {
        public LeagueList()
        {
            AddRange(GetLeague().ToList());
        }

        public IEnumerable<League> GetLeague()
        {
            return from x in Enumerable.Range(1, 2)
                   select new League
                   {
                       Name = "League " + x,
                       Divisions = GetDivisions(x).ToList()
                   };
        }

        public IEnumerable<Division> GetDivisions(int x)
        {
            return from y in Enumerable.Range(1, 3)
                   select new Division
                   {
                       Name = string.Format("Division {0}-{1}", x, y),
                       Teams = GetTeams(x, y).ToList()
                   };
        }

        public IEnumerable<Team> GetTeams(int x, int y)
        {
            return from z in Enumerable.Range(1, 4)
                   select new Team
                   {
                       Name = string.Format("Team {0}-{1}-{2}", x, y, z),
                       Wins = 25 - (x * y * z),
                       Losses = x * y * z
                   };
        }
    }
}
```

Create the view

Next, expose the binding source class from the class that represents your page of markup. We do that by adding a property of type `LeagueList` to **MainWindow**.

C#

```
namespace MasterDetailsBinding
{
    public sealed partial class MainWindow : Window
    {
        public MainWindow()
        {
            InitializeComponent();
            ViewModel = new LeagueList();
        }
        public LeagueList ViewModel { get; set; }
    }
}
```

Finally, replace the contents of the **MainWindow.xaml** file with the following markup, which declares three **CollectionViewSource** instances and binds them together in a chain. The subsequent controls can then bind to the appropriate `CollectionViewSource`, depending on its level in the hierarchy.

XAML

```
<Window
    x:Class="MasterDetailsBinding.MainWindow"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:local="using:MasterDetailsBinding"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    mc:Ignorable="d">

    <Grid>
        <Grid.Resources>
            <CollectionViewSource x:Name="Leagues"
                Source="{x:Bind ViewModel}"/>
            <CollectionViewSource x:Name="Divisions"
                Source="{Binding Divisions, Source={StaticResource
Leagues}}"/>
            <CollectionViewSource x:Name="Teams"
                Source="{Binding Teams, Source={StaticResource
Divisions}}"/>

            <Style TargetType="TextBlock">
                <Setter Property="FontSize" Value="15"/>
                <Setter Property="FontWeight" Value="Bold"/>
```

```
            </Style>
            <Style TargetType="ListBox">
                <Setter Property="FontSize" Value="15"/>
            </Style>
            <Style TargetType="ContentControl">
                <Setter Property="FontSize" Value="15"/>
            </Style>
        </Grid.Resources>

        <StackPanel Orientation="Horizontal">

            <!-- All Leagues view -->
            <StackPanel Margin="5">
                <TextBlock Text="All Leagues"/>
                <ListBox ItemsSource="{Binding Source={StaticResource
Leagues}}"
                         DisplayMemberPath="Name"/>
            </StackPanel>

            <!-- League/Divisions view -->
            <StackPanel Margin="5">
                <TextBlock Text="{Binding Name, Source={StaticResource
Leagues}}"/>
                <ListBox ItemsSource="{Binding Source={StaticResource
Divisions}}"
                         DisplayMemberPath="Name"/>
            </StackPanel>

            <!-- Division/Teams view -->
            <StackPanel Margin="5">
                <TextBlock Text="{Binding Name, Source={StaticResource
Divisions}}"/>
                <ListBox ItemsSource="{Binding Source={StaticResource
Teams}}"
                         DisplayMemberPath="Name"/>
            </StackPanel>

            <!-- Team view -->
            <ContentControl Content="{Binding Source={StaticResource
Teams}}">
                <ContentControl.ContentTemplate>
                    <DataTemplate>
                        <StackPanel Margin="5">
                            <TextBlock Text="{Binding Name}"
                                       FontSize="15" FontWeight="Bold"/>
                            <StackPanel Orientation="Horizontal"
Margin="10,10">
                                <TextBlock Text="Wins:" Margin="0,0,5,0"/>
                                <TextBlock Text="{Binding Wins}"/>
                            </StackPanel>
                            <StackPanel Orientation="Horizontal"
Margin="10,0">
                                <TextBlock Text="Losses:" Margin="0,0,5,0"/>
                                <TextBlock Text="{Binding Losses}"/>
                            </StackPanel>
```

```
                        </StackPanel>
                    </DataTemplate>
                </ContentControl.ContentTemplate>
            </ContentControl>
        </StackPanel>
    </Grid>
</Window>
```

Note that by binding directly to the **CollectionViewSource**, you're implying that you want to bind to the current item in bindings where the path cannot be found on the collection itself. There's no need to specify the `CurrentItem` property as the path for the binding, although you can do that if there's any ambiguity. For example, the **ContentControl** representing the team view has its **Content** property bound to the `Teams` `CollectionViewSource`. However, the controls in the **DataTemplate** bind to properties of the `Team` class because the `CollectionViewSource` automatically supplies the currently selected team from the teams list when necessary.

Windows data binding and MVVM

Article • 06/29/2023

Model-View-ViewModel (MVVM) is a UI architectural design pattern for decoupling UI and non-UI code. With MVVM, you define your UI declaratively in XAML and use data binding markup to link it to other layers containing data and commands. The data binding infrastructure provides a loose coupling that keeps the UI and the linked data synchronized and routes user input to the appropriate commands.

Because it provides loose coupling, the use of data binding reduces hard dependencies between different kinds of code. This makes it easier to change individual code units (methods, classes, controls, etc.) without causing unintended side effects in other units. This decoupling is an example of the *separation of concerns*, which is an important concept in many design patterns.

Benefits of MVVM

Decoupling your code has many benefits, including:

- Enabling an iterative, exploratory coding style. Change that is isolated is less risky and easier to experiment with.
- Simplifying unit testing. Code units that are isolated from one another can be tested individually and outside of production environments.
- Supporting team collaboration. Decoupled code that adheres to well-designed interfaces can be developed by separate individuals or teams, and integrated later.
- Improving maintainability. Fixing bugs in decoupled code is less likely to cause regressions in other code.

In contrast with MVVM, an app with a more conventional "code-behind" structure typically uses data binding for display-only data, and responds to user input by directly handling events exposed by controls. The event handlers are implemented in code-behind files (such as MainWindow.xaml.cs), and are often tightly coupled to the controls, typically containing code that manipulates the UI directly. This makes it difficult or impossible to replace a control without having to update the event handling code. With this architecture, code-behind files often accumulate code that isn't directly related to the UI, such as database-access code, which ends up being duplicated and modified for use with other windows.

App layers

When using the MVVM pattern, an app is divided into the following layers:

- The **model** layer defines the types that represent your business data. This includes everything required to model the core app domain, and often includes core app logic. This layer is completely independent of the view and view-model layers, and often resides partially in the cloud. Given a fully implemented model layer, you can create multiple different client apps if you so choose, such as Windows App SDK and web apps that work with the same underlying data.
- The **view** layer defines the UI using XAML markup. The markup includes data binding expressions (such as x:Bind) that define the connection between specific UI components and various view-model and model members. Code-behind files are sometimes used as part of the view layer to contain additional code needed to customize or manipulate the UI, or to extract data from event handler arguments before calling a view-model method that performs the work.
- The **view-model** layer provides data binding targets for the view. In many cases, the view-model exposes the model directly, or provides members that wrap specific model members. The view-model can also define members for keeping track of data that is relevant to the UI but not to the model, such as the display order of a list of items. The view-model also serves as an integration point with other services such as data access code. For simple projects, you might not need a separate model layer, but only a view-model that encapsulates all the data you need.

Basic and advanced MVVM

As with any design pattern, there is more than one way to implement MVVM, and many different techniques are considered part of MVVM. For this reason, there are several different third-party MVVM frameworks supporting the various XAML-based platforms, including Windows App SDK. However, these frameworks generally include multiple services for implementing decoupled architecture, making the exact definition of MVVM somewhat ambiguous.

Although sophisticated MVVM frameworks can be very useful, especially for enterprise-scale projects, there is typically a cost associated with adopting any particular pattern or technique, and the benefits are not always clear, depending on the scale and size of your project. Fortunately, you can adopt only those techniques that provide a clear and tangible benefit, and ignore others until you need them.

In particular, you can get a lot of benefit simply by understanding and applying the full power of data binding and separating your app logic into the layers described earlier. This can be achieved using only the capabilities provided by the Windows App SDK, and

without using any external frameworks. In particular, the {x:Bind} markup extension makes data binding easier and higher performing than in previous XAML platforms, eliminating the need for a lot of the boilerplate code required earlier.

For additional guidance on using basic, out-of-the-box MVVM, check out the Customers Orders Database UWP sample on GitHub. Many of the other UWP app samples also use a basic MVVM architecture, and the Traffic App UWP sample includes both code-behind and MVVM versions, with notes describing the MVVM conversion.

Files, folders, and libraries with Windows App SDK

Article • 02/08/2024

Packaged Windows App SDK apps can leverage the powerful APIs provided by the Windows.Storage, Windows.Storage.Streams, and Windows.Storage.Pickers namespaces to efficiently read and write various data formats in files, as well as manage files and folders. This section covers essential topics such as reading and writing app settings, file and folder pickers, and accessing special sand-boxed locations like the Video/Music library. Learn how to optimize your app's file management capabilities with the Windows App SDK.

Windows 10 and later OS releases provide a wide variety of APIs related to files, folders, libraries, and settings for apps. These features are available via a combination of WinRT and .NET APIs provided by the Windows SDK and .NET SDK.

Read and write data with WinRT storage APIs

Packaged apps have access to all the WinRT storage APIs available to UWP apps. Whether you're migrating an existing UWP app or creating a new app, you can use these APIs to read and write data. For examples of using the storage APIs in a WinUI app, see Access files and folders with Windows App SDK and WinRT APIs.

Read and write data with .NET file APIs

In addition to the WinRT APIs, packaged apps can use the .NET APIs in the System.IO namespace to read and write data. When a new WinUI 3 project is created, its `Package.appxmanifest` file contains the following setting:

XML

```
<Capabilities>
  <rescap:Capability Name="runFullTrust" />
</Capabilities>
```

Declaring this restricted capability provides full access to the file system, registry, and other restricted capabilities. For more info, see Restricted capability declarations. In other words, the app has the same access to the file system as any other .NET desktop app when using the .NET file APIs.

For examples of using the .NET APIs in a WinUI app, see Access files and folders with Windows App SDK and .NET APIs.

Additional resources for working with files and folders

If you're developing packaged WinUI apps, the WinRT storage APIs can be a powerful tool for reading and writing data. The following UWP topics provide a wealth of information for developers looking to leverage these APIs in their apps.

Expand table

Topic	Description
Enumerate and query files and folders	Access files and folders in either a folder, library, device, or network location. You can also query the files and folders in a location by constructing file and folder queries.
Create, write, and read a file	Read and write a file using a StorageFile object.
Best practices for writing to files	Learn best practices for using various file writing methods of the FileIO and PathIO classes.
Get file properties	Get properties—top-level, basic, and extended—for a file represented by a StorageFile object.
Open files and folders with a picker	Access files and folders by letting the user interact with a picker. You can use the FolderPicker to gain access to a folder. **NOTE:** In a desktop app (which includes WinUI 3 apps), you can use file and folder pickers from Windows.Storage.Pickers. However, if the desktop app requires elevation to run, you'll need a different approach because these APIs aren't designed to be used in an elevated app. For an example, see FileSavePicker.
Save a file with a picker	Use FileSavePicker to let users specify the name and location where they want your app to save a file.
Accessing HomeGroup content	Access content stored in the user's HomeGroup folder, including pictures, music, and videos.
Determining availability of Microsoft OneDrive files	Determine if a Microsoft OneDrive file is available using the StorageFile.IsAvailable property.

Topic	Description
Files and folders in the Music, Pictures, and Videos libraries	Add existing folders of music, pictures, or videos to the corresponding libraries. You can also remove folders from libraries, get the list of folders in a library, and discover stored photos, music, and videos.
Track recently used files and folders	Track files that your user accesses frequently by adding them to your app's most recently used list (MRU). The platform manages the MRU for you by sorting items based on when they were last accessed, and by removing the oldest item when the list's 25-item limit is reached. All apps have their own MRU.
Track file system changes in the background	Track changes to the file system, even when the app isn't running.
Access the SD card	You can store and access non-essential data on an optional microSD card, especially on low-cost mobile devices that have limited internal storage.
Fast access to file properties	Efficiently gather a list of files and their properties from a library to use via the Windows Runtime APIs.

Access files and folders with Windows App SDK and WinRT APIs

Article • 06/29/2023

Packaged Windows App SDK apps can leverage WinRT APIs for reading and writing app settings, file and folder pickers, and special sand-boxed locations such as the Video/Music library. Additionally, any packaged desktop app can utilize both WinRT and Win32 APIs in the Windows SDK, as well as the APIs provided in the .NET SDK. This article provides guidance on how to use the WinRT storage APIs to query files and folders, retrieve file properties, and work with the **Pictures** library.

Query files and folders

The following example shows how to use the StorageFolder and StorageFile APIs to query the **Documents** library for files and folders. The example uses the `GetFilesInFolderAsync` method to recursively iterate through the folder structure and append the file names to a `StringBuilder` object.

C#

```
using System.Text;
using Windows.Storage;
...
private async Task<string> GetDocumentsContentsAsync()
{
    StorageFolder docsFolder = KnownFolders.DocumentsLibrary;
    StringBuilder outputBuilder = new();
    await GetFilesInFolderAsync(docsFolder, outputBuilder);

    return outputBuilder.ToString();
}

private async Task GetFilesInFolderAsync(StorageFolder folder, StringBuilder
outputBuilder)
{
    IReadOnlyList<IStorageItem> storageItem = await folder.GetItemsAsync();

    foreach (var item in storageItem)
    {
        if (item is StorageFolder)
        {
            await GetFilesInFolderAsync(item as StorageFolder,
outputBuilder);
        }
        else
```

```
        {
            outputBuilder.AppendLine($"Found {item.Name} in folder
{folder.Name}");
        }
    }
}
```

Get basic file properties

The following example takes the `GetFilesInFolderAsync` method from the previous example and adds the ability to retrieve the file size and date modified for each file. The example uses the BasicProperties API to retrieve the file size and date modified for each file, formats the file size, and appends the size and date modified to the `StringBuilder` object after each file and folder name.

C#

```
using System.Text;
using Windows.Storage;
using Windows.Storage.FileProperties;
...
private async Task GetFilesInFolderAsync(StorageFolder folder, StringBuilder
outputBuilder)
{
    IReadOnlyList<IStorageItem> storageItem = await folder.GetItemsAsync();

    foreach (var item in storageItem)
    {
        if (item is StorageFolder)
        {
            await GetFilesInFolderAsync(item as StorageFolder,
outputBuilder);
        }
        else
        {
            outputBuilder.AppendLine($"Found {item.Name} in folder
{folder.Name}");

            // Append each file's size and date modified.
            BasicProperties basicProperties = await
item.GetBasicPropertiesAsync();
            string fileSize = string.Format("{0:n0}", basicProperties.Size);
            outputBuilder.AppendLine($" - File size: {fileSize} bytes");
            outputBuilder.AppendLine($" - Date modified:
{basicProperties.DateModified}");
        }
    }
}
```

Working with the Pictures library

In this example, the app is configured to receive notifications when the **Pictures** library is updated. The example uses the StorageLibrary API to retrieve the **Pictures** library and the DefinitionChanged event to receive notifications when the library is updated. The `DefinitionChanged` event is invoked when the list of folders in the current library changes. The example uses the library's `Folders` property to iterate through the folders in the **Pictures** library and writes the folder name to the console.

C#

```
using Windows.Storage;
...
private async Task Configure()
{
    StorageLibrary picturesFolder = await
StorageLibrary.GetLibraryAsync(KnownLibraryId.Pictures);
    picturesFolder.DefinitionChanged += picturesFolder_DefinitionChanged;
}
private void picturesFolder_DefinitionChanged(StorageLibrary sender, object
args)
{
    foreach (StorageFolder item in sender.Folders)
    {
        Console.WriteLine($"Folder {item.Name} found.");
    }
}
```

Access files and folders with Windows App SDK and .NET

Article • 06/29/2023

Packaged Windows App SDK apps can leverage .NET APIs for reading and writing files, working with folders, and reading drive and volume information. Additionally, any packaged desktop app can utilize both WinRT and Win32 APIs in the Windows SDK, as well as the APIs provided in the .NET SDK. This article provides guidance on how to use the .NET System.IO APIs to read and write files, manage drives and folders, and work with memory streams to encode or decode string data.

Read and write files with .NET APIs

In the following example, `ReadWriteFiles` creates a new file, writes a set of integers to the file, and then reads the integers back from the file. The example uses the FileStream class to create a new file and to open the file for reading or writing. The example uses the BinaryWriter class to write the integers to the file and the BinaryReader class to read the integers from the file.

C#

```
using System.IO;
...
ReadWriteFiles("test.bin");
...
private void ReadWriteFiles(string fileName)
{
    if (File.Exists(fileName))
    {
        Console.WriteLine($"{fileName} already exists!");
        return;
    }

    using (FileStream fs = new(fileName, FileMode.CreateNew))
    {
        using BinaryWriter writer = new(fs);
        for (int i = 0; i < 11; i++)
        {
            writer.Write(i);
        }
    }

    using (FileStream fs = new(fileName, FileMode.Open, FileAccess.Read))
    {
        using BinaryReader reader = new(fs);
```

```
        for (int i = 0; i < 11; i++)
        {
            Console.WriteLine(reader.ReadInt32());
        }
    }
}
```

Manage drives and folders in .NET

The following example shows how to use the DirectoryInfo and Directory classes to create, delete, and manage folders. The example uses the `DirectoryInfo` class to create a new directory, create a subdirectory, and delete the directory. The `DirectoryInfo` class provides methods for creating, moving, and enumerating through directories and subdirectories. The `Directory` class provides *static* methods for creating, moving, and enumerating through directories and subdirectories.

C#

```
using System.IO;
...
private void FolderTest()
{
    FolderManagement(@"c:\MyDir", "Projects");
}
private void FolderManagement(string path, string subfolderName)
{
    DirectoryInfo di = new(path);
    try
    {
        // Create directory if it doesn't exist
        if (di.Exists)
        {
            Console.WriteLine("Path already exists.");
        }
        else
        {
            di.Create();
            Console.WriteLine("The directory was created successfully.");
        }

        // Create subdirectory if it doesn't exist
        string subfolderPath = Path.Combine(path, subfolderName);
        if (Directory.Exists(subfolderPath))
        {
            Console.WriteLine("Subfolder path already exists.");
        }
        else
        {
            di.CreateSubdirectory(subfolderName);
```

```
            Console.WriteLine("The subdirectory was created successfully.");
        }

        // Delete directory
        di.Delete(true);
        Console.WriteLine("The directory was deleted successfully.");
    }
    catch (Exception ex)
    {
        Console.WriteLine("The process failed: {0}", ex.ToString());
    }
}
```

This example using the static GetDrives method to retrieve information about all drives on the system. The DriveInfo class provides information about a drive, such as the drive type, label, file system, and available free space.

C#

```
using System.IO;
...
private void DriveManagement()
{
    DriveInfo[] drives = DriveInfo.GetDrives();

    foreach (DriveInfo d in drives)
    {
        Console.WriteLine($"Drive name: {d.Name}");
        Console.WriteLine($"  Drive type: {d.DriveType}");
        if (d.IsReady)
        {
            Console.WriteLine($"  Volume label: {d.VolumeLabel}");
            Console.WriteLine($"  File system type: {d.DriveFormat}");
            Console.WriteLine($"  Space available to user:
{d.AvailableFreeSpace, 15} bytes");
            Console.WriteLine($"  Total available space: {d.TotalFreeSpace,
15} bytes");
            Console.WriteLine($"  Total size of drive: {d.TotalSize, 15}
bytes ");
        }
    }
}
```

Encode and decode strings with MemoryStream

This example shows how to use the MemoryStream class to encode and decode string data. It first creates a `MemoryStream` to asynchronously write a string to a memory stream

and then read the string from the memory stream. The Encoding class is used to convert the string to a byte array and then write the byte array to the memory stream. A StreamReader is then used to asynchronously read the byte array from the memory stream and then convert the byte array back to a string by calling ReadToEndAsync.

C#

```
using System.IO;
using System.Text;
...
private async Task EncodeDecodeStringAsync(string inputData)
{
    using MemoryStream stream = new();
    var inputBytes = Encoding.UTF8.GetBytes(inputData);
    await stream.WriteAsync(inputBytes, 0, inputBytes.Length);
    stream.Seek(0, SeekOrigin.Begin);

    using StreamReader reader = new(stream);
    string text = await reader.ReadToEndAsync();
    Console.WriteLine(text);
}
```

> **Note**
>
> For information about converting between .NET streams and WinRT streams, see **How to: Convert between .NET and Windows Runtime streams**.

Reference for Windows 11 settings

Article • 05/06/2024

The information provided on this page includes details for accessing the status of Windows Backup and Restore settings that are supported in Windows 11. This public documentation ensures effective data portability by providing third-party developers with a streamlined process to access the data. Settings that are supported on both Windows 10 and Windows 11 are documented in Reference for common Windows settings.

Settings status is accessed in one of two ways:

1. Via the Windows registry: For settings below that include registry details, please use that information to access the settings.
2. Via the Cloud Data Store Reader tool. These settings must be extracted from a data store to be readable. If the setting below does not list registry details, then the settings must be extracted using the Cloud Data Store Reader tool. For information on how to use this tool, see Cloud Data Store Settings Reader Tool (readCloudDataSettings.exe).

Cellular

User preferences that customize the Windows behavior when a cellular connection is available.

Registry values under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\WcmSvc\CellularFailover

Expand table

Registry value	Type	Data	Description
AllowFailover	REG_DWORD	0 or 1	Use cellular whenever Wi-Fi is poor.

Registry values under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\WcmSvc\SubscriptionManager\<ICCID>\<IMSI>

Expand table

Registry value	Type	Data	Description
UserCost	REG_DWORD	0 or 1	Maps the metered/unmetered state to each IMSI. 0: Unmetered. 1: Metered.

Registry values under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\WwanSvc\DisallowAutoConnectBy

Expand table

Registry value	Type	Data	Description
<interface GUID>	REG_DWORD	0 or 1	Let Windows keep the device connected to cellular.

Registry values under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\WwanSvc\RoamingPolicyForPhone<interface GUID>

Expand table

Registry value	Type	Data	Description
InternetAlwaysOn	REG_DWORD	0 or 1	Roaming or no roaming. When entering a roaming area, your data connection will be turned off if roaming is not allowed.

Gaming: Game Bar, Game Mode, Gaming Shortcuts

This setting controls settings related to gaming and controls such as Game bar and gaming shortcuts.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\GameDVR

Expand table

Registry value	Type	Data	Description
VKMSaveHistoricalVideo	REG_DWORD	0 or 1	Toggles save historical video enabled.
VKMTakeScreenshot	REG_DWORD	0 or 1	Toggles take screenshot enabled.
VKTakeScreenshot	REG_DWORD	ASCII Value for keys	Key binding for save historical screenshot.
VKSaveHistoricalVideo	REG_DWORD	ASCII Value for keys	Key binding for take screenshot.
VKMToggleBroadcast	REG_DWORD	0 or 1	Toggles broadcast enabled.
VKToggleBroadcast	REG_DWORD	ASCII Value for keys	Key binding for take broadcast.
VKMToggleCameraCapture	REG_DWORD	0 or 1	Toggles camera capture enabled.
VKToggleCameraCapture	REG_DWORD	ASCII Value for keys	Key binding for camera capture.
VKMToggleGameBar	REG_DWORD	0 or 1	Toggles game bar enabled.
VKToggleGameBar	REG_DWORD	ASCII Value for keys	Key binding for game bar.
VKMToggleMicrophoneCapture	REG_DWORD	0 or 1	Toggles microphone capture enabled.
VKToggleMicrophoneCapture	REG_DWORD	ASCII Value for keys	Key binding for microphone capture.
VKMToggleRecording	REG_DWORD	0 or 1	Toggles recording enabled.
VKToggleRecording	REG_DWORD	ASCII Value for keys	Key binding for recording.
VKMToggleRecordingIndicator	REG_DWORD	0 or 1	Toggles recording indicator enabled.
VKToggleRecordingIndicator	REG_DWORD	ASCII Value for keys	Key binding for recording indicator.

Registry values under HKCU\Software\Microsoft\GameBar

Expand table

Registry value	Type	Data	Description
UseNexusForGameBarEnabled	REG_DWORD	0 or 1	Key associated with toggle Gaming -> Game Bar -> "Allow your controller to open Game Bar"
AutoGameModeEnabled	REG_DWORD	0 or 1	Key associated with toggle Gaming -> Game Mode -> Game Mode.

Personalization - Start - Layout - Pins and recommendations

Specifies the start layout type.

Registry values under HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Ad

Expand table

Registry value	Type	Data	Description
Start_Layout	REG_DWORD	0 [Default], 1 [More Pins], 2 [More Recommendations]	The start layout.

Personalization - Start - Recommendations

Specifies whether recommendations for tips, shortcuts, new apps and more are shown.

Registry values under HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Adv

Expand table

Registry value	Type	Data	Description
Start_IrisRecommendations	REG_DWORD	0 or 1	Specifies whether recommendations are enabled.

Personalization - Taskbar - Alignment

This setting sets the alignment of the taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\TaskbarA

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_Al	REG_SZ	0 or 1	Specifies the taskbar alignment. 0 is left aligned. 1 is center aligned.

Personalization - Taskbar - Autohide

This setting sets the auto-hide behavior of the taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\StuckRects3\

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_Autohide	REG_BINARY	A binary blob.	This is an opaque binary blob copied from the following location on the backed up.
SystemSettings_Taskbar_Autohide	REG_BINARY	A binary blob.	This is an opaque binary blob copied from the following location on the backed up.

Personalization - Taskbar - Combine buttons

This setting enables combining buttons and hiding labels on the taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\TaskbarG

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_GroupingMode	REG_SZ	0, 1, or 2	0: Always, 1: When taskbar is full, 2: Never.

Personalization - Taskbar - Flashing

This setting enables flashing for taskbar apps.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\TaskbarF

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_Flashing	REG_SZ	0 or 1	Enables flashing for taskbar apps.

Personalization - Taskbar - Share window

This setting enables sharing any window from taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\TaskbarS

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_Sn	REG_SZ	0 or 1	Enables sharing any window from taskbar.

Personalization - Taskbar - Show desktop

This setting enables showing the desktop by clicking the far corner of the taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\TaskbarS

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_Sd	REG_SZ	0 or 1	Enables showing the desktop by clicking the far corner of the taskbar.

Personalization - Taskbar - Show recent searches

This setting enables showing recent searches when hovering on the search icon in taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Feeds\DSB\OpenOnHover

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_Sh	REG_SZ	0 or 1	Enables showing recent searches when hovering on the search icon in taskbar.

Personalization - Taskbar - Task view

This setting shows or hides the Task View button on the taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\ShowTas

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_TaskView	REG_SZ	0 or 1	Specifies whether the task view button is shown on the taskbar.

Personalization - Taskbar - Widgets button

This setting shows or hides the Widgets button on the taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\TaskbarD

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_Da	REG_SZ	0 or 1	Specifies whether the Widgets button is shown on the taskbar.

Personalization - Themes

This setting is used to set a personalized theme.

Type: Windows.Data.PersonalizationThemes.CurrentThemeType enumeration

CurrentThemeType Values

Expand table

Name	Value	Description
InboxTheme	0	In-box theme.
ContrastTheme	1	Contrast theme.

Type: Windows.Data.PersonalizationThemes.CurrentThemeType structure

CurrentThemeType Properties

Expand table

Name	Type	Description
type	**CurrentThemeType**	The current theme type.
basePersonalizationThemeName	wstring	The name of the current inbox theme applied in the system. The user may have done customization on top of this inbox theme.

Text Input

This setting helps to chose a theme for touch keyboard, voice typing, emoji and more, and input method editors.

Registry values under HKCU\Software\Microsoft\TabletTip\1.7

Expand table

Registry value	Type	Data	Description
IsKeyBackgroundEnabled	REG_DWORD	0 or 1	Indicates if key background is enabled.
KeyLabelSize	REG_DWORD	Min value: 0, Max value: 2	Key label size.
UserKeyboardScalingFactor	REG_DWORD	Min value: 1, Max value: 1000	User keyboard scaling factor.
SelectedThemeIndex	REG_DWORD	Min value: 0, Max value: 15	Selected theme index.
SelectedThemeName	REG_SZ	One of the following values: "LightTheme", "DarkTheme", "ColorPopTheme", "BlackWhiteTheme", "PoppyRedTheme", "IceBlueTheme", "PlatinumTheme", "TangerineTidesTheme", "LilacRiverTheme", "SilkyDawnTheme", "IndigoBreezeTheme", "PinkBlueTheme", "GreenPurpleTheme", "PinkOrangeTheme", "CustomTheme"	Selected theme name.
ThemeDataVersion	REG_DWORD	2	Theme data version.

Typing

This setting contains toggles and other settings related to touch keyboard, text suggestions and preferences.

Registry values under HKCU\Software\Microsoft\input\Settings

Expand table

Registry value	Type	Data	Description
EnableAutoShiftEngage	REG_DWORD	1 or 0	Enables auto shift engage.
EnableDoubleTapSpace	REG_DWORD	1 or 0	Enables double-tap space.
EnableAutocorrection	REG_DWORD	1 or 0	Enables auto-correction.
IsVoiceTypingKeyEnabled	REG_DWORD	1 or 0	Indicates if voice typing key is enabled.
MultilingualEnabled	REG_DWORD	1 or 0	Indicates in multilingual is enabled.
EnableHwkbTextPrediction	REG_DWORD	An integer.	ASCII Value for keys.

VPN

VPN settings that apply to all VPN connections configured in the Settings app.

Registry values under HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RasMan\Parameters

Expand table

Registry value	Type	Data	Description
NoCostedNetwork	REG_DWORD	0 or 1	Block VPN over metered networks.
NoRoamingNetwork	REG_DWORD	0 or 1	Block VPN while roaming.

Wi-Fi

Global random hardware addresses preference.

Registry values under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\WlanSvc\Interfaces\

<Interface GUID>

Expand table

Registry value	Type	Data	Description
RandomMacState	REG_BINARY	00 00 00 00 or 01 00 00 00	Whether to use random hardware addresses for newly configured Wi-Fi networks.

Reference for Windows 11 and Windows 10 settings

Article • 04/03/2024

The information provided on this page includes details for accessing the status of Windows Backup and Restore settings that are supported for both Windows 10 and Windows 11. This public documentation ensures effective data portability by providing third-party developers with a streamlined process to access the data. Settings that are supported on Windows 11 only are documented in Reference for Windows 11 settings.

Settings status is accessed in one of two ways:

1. Via the Windows registry: For settings below that include registry details, please use that information to access the settings.
2. Via the Cloud Data Store Reader tool. These settings must be extracted from a data store to be readable. If the setting below does not list registry details, then the settings must be extracted using the Cloud Data Store Reader tool. For information on how to use this tool, see Cloud Data Store Settings Reader Tool (readCloudDataSettings.exe).

App compatibility

The app compatibility setting is a JSON file that describes compatibility information for apps installed on the device. The path to this JSON is:

`C:\Windows\appcompat\Backup\[user SID].json`

The format of the backup JSON file. Install, Update, and Uninstall nodes contain arrays of applications, which contain arrays of files. The following code segment describes the format of the file and provides descriptions for each field.

JSON

```
{
  "Install": [
    {
      "path": App's uninstall registry path,
      "programId": The unique identifier of the installed Win32 application,
      "compatFlags": Applicable backup/restore compatibility flags OR'ed together. For the list of supported values, see
the table below,
      "restoreAction": Actions to be taken on app restore,
      "files": [
        {
          "name": File name,
          "path": File path,
          "osComponent": Boolean stating if the file is an OS file,
          "size": The file size as a 32-bit value,
          "magic": The PE header's magic number,
          "peHeaderHash": Hash of the file's PE header,
          "sizeOfImage": PE header's SizeOfImage value,
          "peChecksum": PE header's CheckSum value,
          "linkDate": PE header's TimeDateStamp value,
          "linkerVersion": PE header's MarjorImageVersion and MinorImageVersion,
          "binFileVersion": File version obtained from GetFileVersionInfo,
          "binProductVersion": Product version obtained from GetFileVersionInfo,
          "binaryType": Type of binary (e.g. PE64_AMD64),
          "created": File creation time obtained from file system,
          "modified": File modification time obtained from file system,
          "lastAccessed": File access time obtained from file system,
          "verLanguage": Language obtained from GetFileVersionInfo,
          "id": Unique identifier obtained from hashing file contents,
          "switchBackContext": Value for OS runtime compatibility fixes,
          "sigDisplayName": Display name obtained from the file signature,
          "sigPublisherName": Publisher name obtained from the file signature,
          "sigMoreInfoURL": URL obtained from the file signature,
          "fileVersion": File version obtained from GetFileVersionInfo,
          "companyName": Company name obtained from GetFileVersionInfo,
          "fileDescription": File description obtained from GetFileVersionInfo,
          "internalName": Internal name obtained from GetFileVersionInfo,
          "legalCopyright": Copyright information obtained from GetFileVersionInfo,
          "originalFileName": Original filename obtained from GetFileVersionInfo,
          "productName": Product name obtained from GetFileVersionInfo,
          "productVersion": Product version obtained from GetFileVersionInfo,
          "peImageType": Image type obtained from PE header,
          "peSubsystem": Subsystem obtained from PE header,
          "runLevel": Executable's runlevel obtained from app manifest,
          "uiAccess": UI access obtained from app manifest,
          "crcChecksum": File's CRC checksum,
```

```
          "clrVersion": CLR version obtained from app manifest,
          "boeProgramId": Unique ID describing the application,
          "boeProgramName": Same as "productName", if it exists. Otherwise same as "name",
          "boeProgramPublisher": Same as "companyName", if it exists. Otherwise same as "fileDescription", if it exists,
          "boeProgramVersion": Same as "productVersion", if it exists. Otherwise same as "fileVersion", if it exists.
Otherwise same as "binProductVersion", if it exists. Otherwise same as "binFileVersion", if it exists,
          "boeProgramLanguage": Same as "verLanguage", if it exists,
          "fileSize": File's size as a 64-bit number,
          "peCharacteristics": Image characteristics obtained from PE header,
          "sha256": SHA256 hash of file,
        }
      ]
    },
  ],
  "Update": [
    { }
  ],
  "Uninstalled": [
    { }
  ]
}
```

The value of the *compatFlags* field of the backup JSON file is a combination of the following values, computed with an OR operation.

Expand table

Value	Description
0x00000000	App is compatible.
0x00000001	App is incompatible with this OS.
0x00000002	App is developed for specific OEM.
0x00000004	App is a redistributable package.
0x00000008	Plugin or extension that requires the main app.
0x00000010	Middleware.
0x00000020	App was acquired from third party such as a game store.
0x00000040	App is incompatible with HVCI.
0x00000080	App is incompatible with Kernet CET.
0x00000100	App depends on a kernel mode driver.
0x00000200	App is not compatible with Android.
0x00000400	App will not work if S mode is enabled.
0x00000800	App is only available in a certain market.
0x00001000	App does not support this architecture.
0x00002000	App is targeted for other device families.
0x00004000	Generic hardware incompatibility.
0x00008000	App is incompatible up to certain version.

AppList Backup Data

Type: Windows.Data.Apps.AppMetaData structure

AppMetaData values

Unless otherwise specified, the Values are found in the AppXManifest for MSIX packages, and Uninstall registries for other formats.

Expand table

Name	Type	Description
appId	wstring	PackageFamilyName (packaged) or ProductCode (unpackaged).
installSource	wstring	Description of type of installer for the app. See *installSource* for supported values.
lightIconInfo	**IconInfo**	Information about the light icon.
darkIconInfo	**IconInfo**	Information about the dark icon.
appName	wstring	App display name.
publisher	wstring	Publishers name of the app from Add Remove Programs.
lastLaunchTime	uint64	This is a calculated value that represents the last time the app was launched.
appVersion	wstring	Version of the app from Add Remove Programs.
appLanguage	wstring	Language list in Add Remove Programs.
appArch	wstring	Architecture specified in Add Remove Programs.
reinstallId	wstring	Reinstall ID specified in Add Remove Programs.
productUrl	wstring	Product URL Specified in Add Remove Programs.
isPinned	bool	Boolean indicating if this app was pinned to the start menu.
wingetID	wstring	Identifier to indicate if this app can be installed through winget, and the winget ID.
wingetSource	wstring	Specifies where the app was sourced from through the Winget APIs. See *wingetSource* for supported values.

Supported values for the *installSource* field.

Expand table

Value	Description
"Store MSIX"	An MSIX from the Microsoft Store.
"Sideloaded MSIX"	A sideloaded MSIX.
"Edge PWA MSIX"	A PWA MSIX.
"Unknown MSIX"	Not one of the other MSIX values.
"Store Win32"	A non-UWP app from the Microsoft Store.
"Android"	An Android app.
"External MSI"	An external MSI.

Supported values for the *wingetSource* field.

Expand table

Value	Description
"External"	Installed from the web, but winget has an ID a match in the winget catalog.
"Winget"	Installed from the winget catalog.
"Spark"	Microsoft Store non-UWP app.
"MSStore"	Microsoft Store MSIX app.
"NoReliableInfo"	No data provided for source.

Type: Windows.Data.Apps.IconInfo structure

IconInfo values

The paths to the icons used to generate the IconInfo, can be found in the AppXManifest for MSIX packages, and Uninstall registries for other formats.

Expand table

Name	Type	Description
appIconAssetId	wstring	The ID representing an icon from the cloud. The appIconAssetId represents the icon stored in the cloud which was generated from the app installer either through add remove programs metadata or AppxManifest files.
isPlated	bool	Plated or not.

Type: Windows.Data.Apps.ShortcutInfo structure

ShortcutInfo values

Expand table

Name	Type	Description
targetPath	wstring	Link to the executable that launching the tile will shell execute.
shortcutArgs	wstring	Arguments provided on launch.

Type: Windows.Data.Apps.AppLevelTileInfo structure

AppLevelTileInfo values

Expand table

Name	Type	Description
tileId	wstring	UnifiedTileIdentifier for tile
lightIconInfo	**IconInfo**	UnifiedTileIdentifier for light tile
darkIconInfo	**IconInfo**	UnifiedTileIdentifier for dark tile
displayName	wstring	String displayed on tile
sortName	wstring	String value used for sorting in search
packageId	wstring	PackageFamilyName (packaged), ProductCode (unpackaged), empty for unmapped products (appId is specified in **AppMetaData**)
shortcut	**ShortcutInfo**	Shortcut information.
suiteName	wstring	String name for a collection of apps.

Type: Windows.Data.Apps.FileInfo structure

FileInfo values

FileInfo values are populated from the *App Compatibility* JSON above. All FileInfo values are provided as WSTRINGs, though some of the values in the JSON are different.

Expand table

Name	Type	Description
name	wstring	Read from App compatibility JSON. Optional.
path	wstring	Read from App compatibility JSON. Optional.

0b00000010	Gaming
0b00000100	Family
0b00001000	Creativity
0b00010000	Schoolwork
0b00100000	Entertainment
0b01000000	Business
0b10000000	Development

Autoplay

This setting helps to set defaults for removable drives and memory cards

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\AutoplayHandlers

Expand table

Registry value	Type	Data	Description
DisableAutoplay	REG_DWORD	0/1	Toggle the use of autoplay for all media and devices.
UserChosenExecuteHandlers\CameraAlternate\ShowPicturesOnArrival	REG_SZ	A string.	User selected default autoplay behavior for removable drive. See table below for supported values.
UserChosenExecuteHandlers\ StorageOnArrival	REG_SZ	A string.	User selected default autoplay behavior for memory card. See table below for supported values.
EventHandlersDefaultSelection\CameraAlternate\ShowPicturesOnArrival	REG_SZ	A string.	System default autoplay behavior for removable drive. See table below for supported values.
EventHandlersDefaultSelection\StorageOnArrival	REG_SZ	A string.	System default autoplay behavior for memory card. See table below for supported values.

Supported data values for ShowPicturesOnArrival

Expand table

Data value	Description
dsd9eksajf9re3669zh5z2jykhws2jy42gypaqjh1qe66nyek1hg!content!import	Import Photos and Videos (Photos)
MSPlayMediaOnArrival	Play media on arrival.
MSOpenFolder	Open folder.
MSPromptEachTime	Prompt each time.
OneDriveAutoPlay	Import Photos and Videos (OneDrive).
MSTAKENOACTION	Take no action.

Supported data values for StorageOnArrival

Expand table

Data value	Description
MSTAKENOACTION	Take no action.
MSOpenFolder	Open folder.
MSStorageSense	Configure Storage Settings (Settings).
MSPromptEachTime	Prompt each time.

Background

Setting for managing and personalizing the desktop background.

Type: Windows.Data.Background.WallpaperPosition enumeration

WallpaperPosition values

Expand table

Name	Value	Description
Fill	0	Fill.
Fit	1	Fit.
Stretch	2	Stretch.

Name	Value	Description
Tile	3	Tile.
Center	4	Center.
Span	5	Span

Type: Windows.Data.Background.WallpaperKind enumeration

WallpaperKind values

Expand table

Name	Value	Description
SolidColor	0	Solid color.
Image	1	Image.
Slideshow	2	Slideshow.
Spotlight	3	Spotlight.

Type: Windows.Data.Background.DesktopWallpaper structure

The scope of this type is per device.

DesktopWallpaper Properties

Expand table

Name	Type	Description
kind	**WallpaperKind**	Specifies whether current background is set as Wallpaper or Solid Color or Slideshow or Spotlight.
position	**WallpaperPosition**	Specifies how wallpaper or slideshow images are positioned on background.
color	Windows.Data.Common.Color	Specifies the solid color value if background is selected as Solid Color
itemId	wstring	The unique ID for the wallpaper or slideshow uploaded during backup.
contentUri	wstring	The url for the wallpaper or slideshow uploaded during backup.
intervalInSeconds	uint64	The interval between images of slideshow if background is selected as slideshow.
shuffle	bool	Signifies whether slideshow images are shuffled if background is selected as slideshow
syncRootRelativePath	wstring	Signifies path to slideshow folder if background is selected as slideshow.

Calling

The settings below are for a deprecated Windows calling experience and are no longer read by the operating system, however the settings data may be present on user devices or in the cloud.

Type: Windows.data.calling.Settings structure

Settings properties

Name	Type	Description
values	map<wstring, wstring>	A map of key/path settings

Type: Windows.data.calling.callhistoryItem structure

callhistoryItem properties

Expand table

Name	Type	Description
uniqueId	String	Unique identifier for the record.
phoneNumber	String	Phone number of the caller.
calltype	Enum CallType	Possible values: Outgoing, IncomingAnswered, IncomingMissed, IncomingRinging, OutgoingMissed, OutgoingRinging.
voicemailCall	Bool	Indicates whether the call was a voice mail.
videocall	Bool	Indicates whether the call was a video call.
Seen	Bool	Indicates whether the call history was seen by the user.
callerIdBlocked	Bool	Indicates whether the call was blocked.
emergencycall	Bool	Indicates whether call was an emergency call.
linenumber	String	The number of the phone line that received the call.
lineName	String	The phone line's name.
callerLocation	String	Caller location.
callerCategory	String	Caller category.
callerCategoryDescription	String	Caller category description.
Calltimestamp	Unit64	unix time stamp.
Callarrivaltime	Unit64	Unix time the call arrived on the device.
callEndTime	Unit64	Unix time stamp when the call was ended.

Type: Windows.Data.calling.callhistory structure

callhistory Properties

Expand table

Name	Type	Description
historyItems	Map<string, CallHistoryItem>	A collection of call history items where the keys are each history item's UniqueId.
highestSequenceNumber	Unit32	Highest sequence number issued, used for internal business logic.

Type: Windows.data.calling.callfavorites structure

callfavorites Properties

Expand table

Name	Type	Description
favoriteItems	vector<CallFavoriteItem>	A collection of calling favorites.

Type: Windows.data.calling.CallFavoriteItem structure

CallFavoriteItem Properties

Expand table

Name	Type	Description
phoneNumber	String	A collection of calling favorites.
displayName	String	Display name of the favorite.
lineNumber	String	Line number the favorite is associated with.
phoneNumberName	Uint32	Phone number name.
remoteIdHash	String	Remote ID hash.
propHash	String	Property hash.
isVideoCall	Bool	Indicates whether the item is a video call.
isPublicSwitchTelephoneNetwork	Bool	Indicates whether the item is a telephone call.
applicationId	String	Application ID.
callbackToken	String	Callback token.
UniqueId	Unit64	A unique identifier for the item.

Contrast themes

Settings related to high-contrast themes.

Type: Windows.Data.ContrastThemes.CurrentThemeType enumeration

CurrentThemeType values

Expand table

Name	Value	Description
Contrast_Inbox	0	In-box high contrast theme.
Contrast_Custom	1	Customized high contrast theme.
Backup_disabled	2	Backup disabled.

Type: Windows.Data.ContrastThemes.SynchedTheme structure

SynchedTheme properties

Expand table

Name	Value	Description
type	**CurrentThemeType**	Specifies whether current theme is personalized theme or inbox high contrast theme or customized high contrast theme.

Name	Value	Description
currentThemePath	wstring	The complete path to the currently applied theme file.
contrastThemePath	wstring	The complete path to the last applied high contrast theme file.This can be same as of *currentThemePath* if current theme is high contrast.
baseContrastThemeName	wstring	Specifies the base in-box high contrast theme is applied. Any customization may have been applied on top of these themes. Supported values are "High Contrast #1", " or "High Contrast #2", "High Contrast Black", or "High Contrast White"
customThemeName	wstring	The user-defined name for a customized contrast theme.
rgbBackground	**Windows.Data.Common.Color**	Theme background color.
rgbText	**Windows.Data.Common.Color**	Theme text color.
rgbHyperlink	**Windows.Data.Common.Color**	Theme hyperlink color.
rgbInactiveText	**Windows.Data.Common.Color**	Theme inactive text color.
rgbSelectedText1	**Windows.Data.Common.Color**	Signifies color value of Text of highlighted text.
rgbSelectedText2	**Windows.Data.Common.Color**	Signifies color value of Text of highlight.
rgbButtonText1	**Windows.Data.Common.Color**	Signifies color value of Text of button text.
rgbButtonText2	**Windows.Data.Common.Color**	Signifies color value of Face of button.

Type: Windows.Data.Common.Color structure

Color values

Expand table

Name	Value	Description
red	uint8	Red channel value of an RGBA color.
green	uint8	Green channel value of an RGBA color.
blue	uint8	Blue channel value of an RGBA color.
alpha	uint8	Alpha channel value of an RGBA color.

Date and Time

Settings related to date and time.

Registry values under HKLM\SYSTEM\CurrentControlSet\Services\tzautoupdate

Expand table

Registry value	Type	Data	Description
start	REG_DWORD	3/4	3: Set timezone toggle value on. 4: Set Timezone toggle value off.

Registry values under HKLM\SYSTEM\CurrentControlSet\Control\TimeZoneInformation

Expand table

Registry value	Type	Data	Description
timeZone	REG_SZ	System timezone as string.	The currently set time zone for the system.

Do not disturb

Set "do not disturb" status manually or automatically, so that notifications will be sent directly to the notification center.

Type: Windows.Data.DoNotDisturb.ChangeReason enumeration

ChangeReason values

Expand table

Name	Value	Description
Default	0	Default setting.
User	1	User setting.

Type: BoolWithMetadata structure

BoolWithMetadata properties

Expand table

Name	Value	Description
value	bool	The boolean value.
changeReason	**ChangeReason**	The reason a user changed their profile.

Type: Windows.Data.DoNotDisturb.QuietHoursProfile structure

This setting is multi-instance. The following is an example command line for retrieving this type:

```
readCloudDataSettings.exe enum -type:windows.data.donotdisturb.QuietHoursProfile
```

For more information on retrieving multi-instance settings, see Cloud Data Store Settings Reader Tool.

QuietHoursProfile Properties

Expand table

Name	Type	Description
isInitialized	bool	CDS data initialize status.
settings	map<uint64, bool>	Map of the boolean state of the settings. Specifies when a given settings checkbox is checked or unchecked.
allowedContacts	set<wstring>	The set of allowed contacts as a list.
allowedApps	set<wstring>	The list of app names to set notifications on.
defaultAllowedAppsRemoved	set<wstring>	The list of names of the default app names removed.

Type: Windows.Data.DoNotDisturb.QuietHoursSettings structure

QuietHoursSettings Properties

Expand table

Name	Type	Description
isInitialized	bool	CDS data initialize status. .

Name	Type	Description
selectedProfile	wstring	The string value of the user profile. "Unrestricted" or "Priority Only"
shouldShowSummaryToast	BoolWithMetadata	Sets whether the summary toast should be shown and the associated reason.

Type: Windows.Data.DoNotDisturb.QuietMoment structure

This setting is multi-instance. The following is an example command line for retrieving this type:

```
readCloudDataSettings.exe enum -type:windows.data.donotdisturb.quietmoment
```

For more information on retrieving multi-instance settings, see Cloud Data Store Settings Reader Tool.

QuietMoment Properties

Expand table

Name	Type	Description
isInitialized	bool	CDS data initialize status. Default value is false.
isEnabled	bool	Settings enabled or disabled.
assignedProfile	wstring	The value of the user profile set by automatic rules. "Unrestricted", "Priority Only", or "Alarms Only"
startTime	TimeSpan	When automatic rules should start.
endTime	TimeSpan	When automatic rules should end.
repeatType	uint32	How frequently the rules should apply. "Daily", "Weekend", or "Weekdays"
shouldShowActiveToast	BoolWithMetadata	Sets whether the active toast should be shown and the associated reason.

File Explorer Classic

Settings related to the classic Windows File Explorer.

Type: Windows.Data.FileExplorerClassic.ShellStateSetting structure

ShellStateSetting Properties

Expand table

Name	Type	Description
bmigratedFromSSF	bool	Indicates whether the shell state is migrated from legacy setting framework to current solution.
bshowAllObjects	bool	Indicates whether Shell state should show all objects.
bshowExtensions	bool	Indicates whether Shell state should show all extensions.
bshowCompColor	bool	Indicates whether Shell state should show all colors.
bdoubleClickInWebView	bool	Indicates whether Shell state should show all objects.
bdontPrettyPath	bool	Indicates whether Shell state should show pretty path
showInfoTip	bool	Indicates whether Shell state should show info tip.
noConfirmRecycle	bool	Indicates whether Shell state should should confirm recycle option.
showSuperHidden	bool	Indicates whether Shell state should show super hidden.
sepProcess	bool	Indicates whether Shell state should show the separation process.
iconsOnly	bool	Indicates whether Shell state should show icons only.
showTypeOverlay	bool	Indicates whether Shell state should show type overlay.

Type: Windows.Data.FileExplorerClassic.CabinetStateSettings structure

CabinetStateSettings Properties

Expand table

Name	Type	Description
migratedFromSSF	bool	Indicates whether the cabinet state is migrated from legacy setting framework to current solution.
fullPathTitle	bool	Indicates whether the cabinet state setting should show full path title.
saveLocalView	bool	Indicates whether the cabinet state setting should save local view.
newWindowMode	bool	Indicates whether the cabinet state setting should open in new window mode.

Type: Windows.Data.FileExplorerClassic.AdvancedSettings structure

Expand table

Name	Type	Description
migratedFromSSF	bool	Indicates whether advanced settings are migrated from legacy setting framework to current solution.
alwaysShowMenus	bool	Indicates whether advanced settings should always show menu.
folderContentsInfoTip	bool	Indicates whether advanced settings should show folder contents info tip.
hideDrivesWithNoMedia	bool	Indicates whether advanced settings should hide the drives with no media present.
navPaneExpandToCurrentFolder	bool	Indicates whether advanced settings should expand the navigation pane to current folder.
navPaneShowAllFolders	bool	Indicates whether advanced settings should expand the navigation panel to show all folders.
navPaneShowFavorites	bool	Indicates whether advanced settings should expand the navigation panel to show all favorites.
persistBrowsers	bool	Indicates advanced settings for file explorer should persist browsers.
sharingWizardOn	bool	Indicates whether sharing wizard is on for advanced settings.
showDriveLetters	bool	Indicates whether drives letters are shown for advanced settings.
showPreviewHandlers	bool	Indicates whether to show preview handlers.
typeAhead	bool	Indicates whether to show type ahead.
showStatusBar	bool	Indicates whether the file explorer should show status bar.
showLibraries	bool	Indicates whether the file explorer advanced settings should show libraries.
showCompColor	bool	Indicates whether to show comp color for advanced settings.

Type: Windows.Data.FileExplorerClassic.ExplorerSettings structure

ExplorerSettings Properties

Expand table

Name	Type	Description
migratedFromSSF	bool	Indicates whether the explorer settings are migrated from legacy setting framework to current solution.
underlineIconsAlways	bool	Indicates whether Explorer settings should always underline icons.
underlineIconsNever	bool	Indicates whether Explorer settings should never underline icons.
underlineIconsAsBrowser	bool	Indicates whether Explorer settings should underline icons as browser.

Type: Windows.Data.FileExplorerClassic.SearchSettings structure

SearchSettings Properties

Expand table

Name	Type	Description
migratedFromSSF	bool	Indicates whether the search settings are migrated from legacy setting framework to current solution.
searchOnly	bool	Indicates whether search setting show search only.
wholeFileSystem	bool	Indicates whether search setting show the whole file system.
systemFolders	bool	Indicates whether search setting show system folders.
archivedFiles	bool	Indicates whether search setting show archived files.

Type: Type: Windows.Data.FileExplorerClassic.RegistrySettings structure

These are blobs that are in the registry. There are three things that use registry stream settings:

Expand table

Name	Type	Description
migratedFromSSF	bool	Indicates whether the registry settings are migrated from legacy setting framework to current solution.
RibbonQat	blob	A single blob.
detailsPreviewPaneSettings	unit32	Details about preview pane settings.
readingPaneSettings	unit32	Indicates reading pane settings.
navigationPaneVisible	bool	Indicates whether navigation pane is visible or not.

RegistrySettingsProperties

Expand table

Name	Type	Description
migratedFromSSF	bool	Indicates whether registry settings are migrated from legacy setting framework to current solution.
ribbonQat	blob	A single blob.
detailsPreviewPaneSettings	unit32	Details about preview pane settings.
readingPaneSettings	unit32	Indicates reading pane settings.
navigationPaneVisible	bool	Indicates whether navigation pane is visible or not.

Type: Windows.Data.FileExplorerClassic.FolderOptionGeneralSettings structure

These are settings found in File Explorer->Folder options(...)->General tab

- File explorer can be opened to either Home or This PC
- File explorer can be opened to One Drive folder as well if user has signed in to One Drive (This option is available only if user has signed in)

FolderOptionGeneralSettings Properties

Expand table

Name	Type	Description
defaultOpenLocation	unit8	Indicates whether file explorer can be opened to either home or this PC. Default is home (0).

Name	Type	Description
browseFoldersInNewWindow	bool	Indicates whether to browse folder in new window.
useDoubleClickToOpen	bool	Indicates whether to use double click to open.
showRecentlyUsedFiles	bool	Indicates whether to show recently used files.
showFrequentlyUsedFolders	bool	Indicates whether to show frequently used folders.
showFilesFromOffice	bool	Indicates whether to show files from MS office.

Type: Windows.Data.FileExplorerClassic.FolderOptionsAdvancedSettings structure

These are settings found in File Explorer->Folder options(...)->View tab->Advanced settings

FolderOptionsAdvancedSettings Properties

Expand table

Name	Type	Description
alwaysShowIconsNeverThumbnails	bool	This is used to show icons only.
compactView	bool	Decrease space between items.
displayFileIconOnThumbnails	bool	Indicates whether to display file icon on thumbnails.
displayFileSizeInfoInFolderTips	bool	Indicates whether to display file size information in folder tips.
displayFullFilePath	bool	Show folder contents info tip.
showSysHiddenFiles	bool	Show/hide hidden files and folders.
hideEmptyDrives	bool	Hide drives with no media.
showExtensions	bool	Show/hide extensions of known file types.
hideFolderMergeConflicts	bool	Indicates whether to show/hide folder merge conflicts.
showSuperHiddenOSProtectedFiles	bool	Show/hide OS protected files.
showDriveLetters	bool	Show/hide drive letters.
colorEncryptedCompressedFiles	bool	Show encrypted and compressed files in color.
showPopupDescription	bool	Indicates pop up descriptions.
showSyncProviderNotification	bool	Indicates notification provider sync notification.
useCheckboxesForSelection	bool	Used to show check boxes for selection.
useSharingWizard	bool	Sharing wizard on/off.
navPaneAlwaysShowAvailablityStatus	bool	Show Navigation pane all cloud states.
navPaneShowLibraries	bool	Show navigation pane libraries.
navPaneShowNetwork	bool	Show pane navigation network.
navPaneShowThisPC	bool	This is used to show navigation pane to show current folder.

Type: Windows.Data.FileExplorerClassic.RecycleBinSettings structure

These are settings found in Recycle bin-> right click Properties

RecycleBinSettings Properties

Expand table

Name	Type	Description
displayDeleteConfirmationDialog	bool	Indicates whether to show delete confirmation dialog

Type: Windows.Data.FileExplorerClassic.DesktopIconSettings structure

These are settings related to desktop icons.

DesktopIconSettings Properties

Expand table

Name	Type	Description
viewAutoArrangeIcons	bool	Indicates values for AutoArrangement of icons.
viewAlignIconsToGrid	bool	Indicates values for snapping to grid.
viewShowDesktopIcons	bool	Indicates values to view desktop icons.
sortColPropertyKeyFmtid	wstring	L"B725F130-47EF-101A-A5F1-02608C9EEBAC".
sortColPropertyKeyPid	Unit32	10.
sortColDirection	bool	1=Ascending -1=Descending Default value is Ascending (true).

Input Method Editors (IME)

History files are used to optimize the Japanese IME user experience across devices.

Type: Windows.Data.Input.HistoryFiles structure

This type is multi-instance and must be retrieved using the following collection collection names:

- "historyfiles"

The following is an example command line for retrieving this type:

```
readCloudDataSettings.exe enum -type:Windows.Data.Input.HistoryFiles -collection:historyfiles
```

For more information on retrieving multi-instance settings, see Cloud Data Store Settings Reader Tool.

HistoryFiles Properties

Expand table

Name	Type	Description
InputDataFiles	Map<string,FilePathInfo>	A map of input history FilePathInfo structs where the key represents a relative folder path.

Type: Windows.Data.Input.FilePathInfo structure

FilePathInfo Properties

Expand table

Name	Type	Description
filePath	Map<string,fileData>	A map of FileData structs where the key is the file name.

Type: Windows.Data.Input.FileData structure

FileData Properties

Expand table

Name	Type	Description
filePath	blob	Raw input data, byte array serialized as a collection of integers.

Internet Explorer

Although Internet explorer has reached end of life, some settings stored by the browser may remain in the cloud or on Windows through settings backup.

The **SettingUnit** structure used with the following settings has the following definition:

C++

```
struct SettingUnit
{
    String settingType
    String settingUnitID
    FILETIME timeStamp
    blob settingData
}
```

Type: Windows.Data.InternetExplorer.Favorites structure

Favorites Properties

Expand table

Name	Type	Description
favoriteSettings	vector<**SettingUnit**>	**SettingUnit** structures related to Internet Explorer favorites.

Type: Windows.Data.InternetExplorer.TypedURLS structure

TypedURLS Properties

Expand table

Name	Type	Description
typedURLSettings	vector<**SettingUnit**>	**SettingUnit** structures related to Internet Explorer TypedURLS.

Type: Windows.Data.InternetExplorer.BrowserHistory structure

BrowserHistory Properties

Expand table

Name	Type	Description
BrowserHistory	vector<**SettingUnit**>	**SettingUnit** structures related to Internet Explorer browser history.

Type: Windows.Data.InternetExplorer.AutoComplete structure

AutoComplete Properties

Expand table

Name	Type	Description
AutoCompleteSetting	vector<**SettingUnit**>	**SettingUnit** structures related to Internet Explorer autocomplete.

Type: Windows.Data.InternetExplorer.TabRoaming structure

TabRoaming Properties

Expand table

Name	Type	Description
TabRoamingSetting	vector<**SettingUnit**>	**SettingUnit** structures related to Internet Explorer tab roaming settings.

Lock screen

Setting for managing and personalizing the lock screen.

Type: Windows.Data.LockScreenSettings.LockScreenKind enumeration

LockScreenKind values

Expand table

Name	Value	Description
Picture	0	Picture.
Slideshow	1	Slideshow
Spotlight	2	Spotlight

Type: Windows.Data.LockScreenSettings structure

The scope of this type is per device.

LockScreenSettings Properties

Expand table

Name	Type	Description
kind	**LockScreenKind**	Specifies whether current Lockscreen is set as Wallpaper or Slideshow or Spotlight
pictureOnSignInScreen	bool	Specifies whether show the lock screen background picture on the sign-in screen is enabled.
funItems	bool	Specifies whether "Get fun facts, tips, tricks, and more on your lock screen" is enabled.
itemId	wstring	The unique ID for the lockscreen wallpaper uploaded to during backup.
contentUri	wstring	The url for the lockscreen wallpaper uploaded to during backup
lockScreenStatus	wstring	Not used.
slideShowAutoLock		Not used.
slideShowEnabledOnBattery		Not used.
slideshowOptimizePhotoSelection		Not used.
slideShowIncludeCameraRoll		Not used.
slideShowDuration		Not used.

Name	Type	Description
syncRootRelativePaths		Not used.

Lunar calendar

Settings related to the lunar Calendar in the task bar.

Type: Windows.Data.LunarCalendar structure

LunarCalendar Properties

Expand table

Name	Type	Description
languageType	**LunarCalendarLanguageType**	A member of the **LunarCalendarLanguageType** enumeration. The default value is **Default**.

Type: Windows.Data.LunarCalendarPerDevice structure

This type inherits from **LunarCalendar**. The scope of this type is per device.

Type: Windows.Data.LunarCalendarLanguageType enumeration

LunarCalendarLanguageType Values

Expand table

Name	Value	Description
Default	0	The default lunar calendar configuration.
None	1	No lunar calendar.
SimplifiedChinese	2	The Simplified Chinese lunar calendar.
TraditionalChinese	3	The Traditional Chinese calendar.

Multiple displays

Settings related to multiple displays.

Type: Windows.Data.Settings.DisplaySettings.MultipleDisplays structure

The scope of this type is per device.

MultipleDisplays Properties

Expand table

Name	Type	Description
rememberWindowLocationsPerMonitorConnection	nullable<bool>	Enables remember window locations per monitor connection
minimizeWindowsOnMonitorDisconnect	nullable<bool>	Enables minimize windows on monitor disconnect.
easeCursorMovementBetweenDisplays	nullable<bool>	Enables minimize windows on monitor disconnect.

Nightlight

Settings related to changing screen lighting or set brightness for certain hours.

Type: Windows.Data.BlueLightReduction.ScheduleTime structure

The scope of this type is per device.

ScheduleTime Properties

Expand table

Name	Type	Description
hour	int8	Hours.
minute	int8	Minutes.

Type: Windows.Data.BlueLightReduction.Settings structure

BlueLightReduction.Settings Properties

Expand table

Name	Type	Description
automaticOnSchedule	bool	Specifies whether blue light reduction is automatically turned on or off based on a schedule.
automaticOnSunset	bool	Specifies if blue light reduction schedule is automatically set based on sunrise and sunset.
manualScheduleBlueLightReductionOnTime	**ScheduleTime**	The start time of blue light reduction for a user manually setting their schedule.
manualScheduleBlueLightReductionOffTime	**ScheduleTime**	The end time of blue light reduction for a user manually setting their schedule.
targetColorTemperature	**int16**	The target color temperature (in Kelvin) for blue light reduction.
sunsetTime	**ScheduleTime**	The scheduled sunset time for blue light reduction.
sunriseTime	**ScheduleTime**	he scheduled sunrise time for blue light reduction.
previewColorTemperatureChanges	bool	Specifies whether blue light reduction color temperature changes should be previewed.
darkMode	bool	Specifies whether app mode should change when blue light reduction is turned on or off

Type: Windows.Data.BlueLightReduction.ActiveState enumeration

ActiveState values

Expand table

Name	Value	Description
BlueLightReductionOn	0	
BlueLightReductionOff	1	

Type: Windows.Data.BlueLightReduction.ChangeSource enumeration

ChangeSource values

Expand table

Name	Value	Description
Schedule	0	
User	1	

Type: Windows.Data.BlueLightReduction.BlueLightReductionState structure

BlueLightReductionState Properties

Expand table

Name	Type	Description
state	**ActiveState**	The current state of blue light reduction.
source	**ChangeSource**	Where the change came from, user change or scheduled change.
timestampUTC	int64	The time the change in active state was applied.
isSupported	bool	Whether or not current configuration supports blue light reduction.

NlmSignature

Settings related to Nlm signatures. Each network is uniquely identified with a network signature based on the uniquely identifiable properties of that network.

Type: Windows.Data.Nlm.NlmSignature structure

This type is multi-instance and must be retrieved using the following collection names:

- "wificloudstore3"
- "wifi3_wpa3"
- "wifi3_owe"

The following is an example command line for retrieving this type:

```
readCloudDataSettings.exe enum -type:windows.data.nlm.nlmsignature -collection:wificloudstore3
```

For more information on retrieving multi-instance settings, see Cloud Data Store Settings Reader Tool.

NlmSignature Properties

Expand table

Name	Type	Description
category	uint64	Category of signature.

Pen and Windows Ink

Settings related to pen and Windows Ink.

Type: Windows.Data.Input.Devices.PenPerDevice structure

PenPerDevice Properties

Expand table

Name	Type	Description
singleClickOverride	uint64	Any integer value 0 - 13. Value corresponds to options available for Single Click setting dropdown.
singleClickPenWorkspaceVerb	uint64	Any integer value 0-3. Value corresponds to options available for Single Click setting dropdown.
doubleClickOverride	uint64	Any integer value 0 - 13. Value corresponds to options available for Double Click setting dropdown.
doubleClickPenWorkspaceVerb	uint64	Any integer value 0-3. Value corresponds to options available for Double Click setting dropdown.
longPressOverride	uint64	Any integer value 0 - 13. Value corresponds to options available for long press setting dropdown.
longPressPenWorkspaceVerb	uint64	Any integer value 0-3. Value corresponds to options available for Long Press setting dropdown.
penWorkspaceAppLaunchOnPenDetachEnabled	bool	Specifies whether the pen menu is shown after pen is removed from storage.
penEnablePenButtonOverride	bool	Specifies whether apps are allowed to override the shortcut button behavior.
singleClickCustomAppPath	wstring	Specifies the path to the app opened on single-click.
doubleClickCustomAppPath	wstring	Specifies the path to the app opened on double-click.
longPressCustomAppPath	wstring	Specifies the path to the app opened on long-press.
singleClickCustomAppID	wstring	Specifies the app ID app opened on single-click.
doubleClickCustomAppID	wstring	Specifies the app ID app opened on double-click.
longPressCustomAppID	wstring	Specifies the app ID app opened on long-press.

Supported override and verb values:

Expand table

Dropdown Option Selected	Override	PenWorkspaceVerb	Override (Win10)	PenWorkspaceVerb (Win10)
Nothing	1	0/1	1	0
Screen Snipping	8	0/1	8	0
Pen Menu	5	0	5	0
Whiteboard	9	0	5	2
One Note	6	0/1	0	0
One Note Quick Notes	13	0/1	NA	NA
Sticky Notes	5	1	5	1
Snip & Sketch	NA	NA	5	3
Open Program	3	0	3	0
Open App	2	0	2	0

Personalization - colors

Settings related to system colors.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Themes\Personalize

Expand table

Registry value	Type	Data	Description
AppsUseLightTheme	REG_DWORD	0/1	Signifies light/dark color mode for an app.
SystemUsesLightTheme	REG_DWORD	0/1	Signifies light/dark color mode for Windows.
EnableTransparency	REG_DWORD	0/1	Signifies the transparency effect on windows and surfaces.
ColorPrevalance	REG_DWORD	0/1	Signifies the toggle state for "Show Accent Color on Start and Taskbar".

Registry values under HKCU\Control Panel\Desktop

Expand table

Registry value	Type	Data	Description
AutoColorization	REG_DWORD	0/1	signifies auto-apply accent color based on background or manually.

Expand table

Registry value	Type	Data	Description
ColorPrevalence	REG_DWORD	0/1	Signifies toggle state for "show Accent color in title bar and windows borders".

Personalization - Start - Folders

Specifies the folders that are shown at the bottom of the Start menu.

Registry values under HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Start

Expand table

Registry value	Type	Data	Description
VisiblePlaces	REG_BINARY	A vector of GUIDs.	A list of GUIDs indicating the folders that are shown at the bottom of Start.

The folder GUIDs that are supported for *Start_Layout* are:

- Documents: {2D34D5CE-FA5A-4543-82F2-22E6EAF7773C}
- Downloads: {E367B32F-89DE-4355-BFCE-61F37B18A937}
- Music: {B00B0620-7F51-4C32-AA1E-34CC547F7315}
- Pictures: {383F07A0-E80A-4C80-B05A-86DB845DBC4D}
- Videos: {42B3A5C5-7D86-42F4-80A4-93FACA7A88B5}
- Network: {FE758144-080D-42AE-8BDA-34ED97B66394}
- UserProfile: {74BDB04A-F94A-4F68-8BD6-4398071DA8BC}
- Explorer: {148A24BC-D60C-4289-A080-6ED9BBA24882}
- Settings: {52730886-51AA-4243-9F7B-2776584659D4}

Personalization - Start - Layout

Specifies the start layout.

Registry values for layout under HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Start

Expand table

Registry value	Type	Data	Description
Config	REG_BINARY	A JSON file.	The contents of the Pinned Layout in JSON.

Personalization - Start - Show recent apps

Specifies whether apps that were recently installed in Start in various surfaces are shown on Start.

Registry values for recent apps under HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Start

Expand table

Registry value	Type	Data	Description
ShowRecentList	REG_BOOL	0 or 1	Specifies whether apps that were recently installed in Start in various surfaces are shown on Start.

Personalization - Start - Show recommended apps

Specifies whether recommended files in Start, recent files in File Explorer, and items in Jump Lists are shown.

Registry values under HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Ad

Expand table

Registry value	Type	Data	Description
Start_TrackDocs	REG_BOOL	0 or 1	Specifies whether recommended files in Start, recent files in File Explorer, and items in Jump Lists are shown.

Personalization - Taskbar - Badges

This setting enables badges for apps on the taskbar.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\TaskbarE

Expand table

Registry value	Type	Data	Description
SystemSettings_Taskbar_Badging	REG_SZ	0 or 1	Enables badges for apps on the taskbar.
SystemSettings_DesktopTaskbar_Badging	REG_SZ	0 or 1	Enables badges for apps on the taskbar.

Personalization - Taskbar - Combine buttons, mult-monitor

This setting enables combining buttons and hiding labels on the taskbar on multiple monitors.

Registry values under HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced\MMTask

Expand table

Registry value	Type	Data	Description
SystemSettings_DesktopTaskbar_GroupingMode	REG_SZ	0, 1, or 2	0: Always, 1: When taskbar is full, 2: Never.

AccountInfo Properties

Expand table

Name	Type	Description
accountName	wstring	The user name of the account such as "example@outlook.com".
accountId	wstring	The unique identifier of the account.
accountType	**AccountType**	The type of the account.
country	wstring	The code of the country or region in which a MSA is registered.
safeCustomerId	wstring	An alternative identifier for an MSA.
ageGroup	wstring	Age group of an MSA, based on the registered birth date of the MSA user. Current values are 0 = unknown, 1 = child, 2 = teen, 3 = adult.
scope	wstring	Represents the "Sign in options" setting state.

Type: Windows.Data.Account.SecondaryAccounts structure

SecondaryAccounts Properties

Expand table

Name	Type	Description
accountDetails	vector<AccountInfo>	A vector of **AccountInfo** objects representing secondary accounts.

Spelling dictionary

The user's custom spelling dictionary is stored in a file in the following file path:

`%userprofile%\AppData\Roaming\Microsoft\Spelling\neutral\default.dic`

USB

This setting controls toggles such as connection notifications, battery saver and other notifications related to charging of PC.

Registry values under HKCU\Software\Microsoft\Shell\USB

Expand table

Registry value	Type	Data	Description
NotifyOnUsbErrors	REG_DWORD	0 or 1	Enables notifications for USB errors.
NotifyOnWeakCharger	REG_DWORD	0 or 1	Enables notifications for weak charger detected.

Windows Backup - Remember my preferences

Helps user to synchronize the settings and Data on multiple machines.

Type: Windows.Data.WindowsBackup.Preference.CloudStorePolicyEnum enumeration

CloudStorePolicyEnum values

Expand table

Name	Value	Description
SyncEnabled	0	Sync enabled.
SyncDisabledByUser	1	Sync disabled by user.
SyncDisabledByGroupPolicy	2	Sync disabled by group policy.

Toggles properties

Expand table

Name	Type	Description
toggleState	map<wstring, **CloudStorePolicyEnum**>	The user preference in terms of mapping of sync policy and CloudStorePolicy option. Allowed values for sync policy names are listed below.

Valid sync policy names:

- Microsoft
- MicrosoftDevice
- MicrosoftUserProfile
- Microsoft.Accessibility
- MicrosoftDevice.Accessibility
- MicrosoftUserProfile.Accessibility
- Microsoft.Credentials
- MicrosoftDevice.Credentials
- MicrosoftUserProfile.Credentials
- Microsoft.Personalization
- MicrosoftDevice.Personalization
- MicrosoftUserProfile.Personalization
- Microsoft.Language
- MicrosoftDevice.Language
- MicrosoftUserProfile.Language
- Microsoft.Default
- MicrosoftDevice.Default
- MicrosoftUserProfile.Default
- Microsoft.Ink
- MicrosoftDevice.Ink
- MicrosoftUserProfile.Ink

Windows Update

Settings related to Windows Update.

Registry values under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\WindowsUpdate\UX\Settings

Expand table

Registry value	Type	Data	Description
IsContinuousInnovationOptedIn	REG_DWORD	0/1	Enables devices to get the latest updates as soon as they're released.
AllowMUUpdateService	REG_DWORD	0/1	Allows users to get other Microsoft products alongside with Windows Updates.
IsExpedited	REG_DWORD	0/1	User selects this to invoke device restart 15 min after all updates finished installing.
RestartNotificationsAllowed2	REG_DWORD	0/1	Users decides if they want to be notified about the updates pending restart.

Cloud Data Store Settings Reader tool (readCloudDataSettings.exe)

Article • 03/06/2024

This article describes the Cloud Data Store Settings Reader Tool, readCloudDataSettings.exe, that can be used to fetch data stored within the Windows Cloud Data Store component on the local device. For settings documented in Reference for Windows 11 settings or Reference for Windows 11 and Windows 10 settings, if the setting lists a type name rather than a registry key, then you must use this tool to retrieve the data.

Usage

Single instance items

```
readCloudDataSettings.exe get -type:<type name> [-account:<secondary account id>]
```

Multi-instance items

```
readCloudDataSettings.exe enum -type:<type name> [-collection:<collection name>] [-account:<secondary account id>]
```

Command line parameter descriptions

Expand table

Parameter	Description
`<type name>`	The name of a Cloud Data Store type whose data is to be retrieved (e.g., "windows.data.platform.diagnostics.diagnosticdata")
`<collection name>`	The optional name of a collection for a Cloud Data Store multi-instance type. This must be specified if the multi-instance type has a named collection and must not be specified if either the collection has no name or the type is single-instance. Cloud Data Store does has no support for enumerating either the data or names of all collections of a type.
`<secondary account id>`	The optional id (in the form of user@domain) of a secondary account associated with the current user whose data is to be fetched. This must be a secondary

Parameter	Description
	account associated with the currently logged in Windows user; it does not provide access to data for other Windows users that might be sharing the device.

Errors

If the data does not exist or an error occurs, the output will report a pair of square brackets with nothing between; example:

PowerShell

```
[
]
```

Examples

Single-instance type

Command line:

PowerShell

```
C:\Windows\System32>readCloudDataSettings.exe get -
type:windows.data.settings.settingsusagehistory
```

Output:

PowerShell

```
/type: windows.data.settings.settingsusagehistory

[
{"Data":{"pageUsages":{"\"SettingsPageAppsNotifications\"":{"Data":
{"frequency":1,"lastUsedTime":1.3353819570909629E+17,"lastUsedSettingId":"Sy
stemSettings_Notifications_QuietHours_MuteNotification_Enabled"}},"\"Setting
sPageOtherUsers\"":{"Data":
{"frequency":1,"lastUsedTime":1.3353709031552022E+17,"lastUsedSettingId":"Sy
stemSettings.UserAccountsHandlers.RemoveOtherUserSetting"}}}}}
]
```

Single-instance type, alternate account

Command line:

```PowerShell
C:\Windows\System32>readCloudDataSettings.exe get -
type:windows.data.settings.settingsusagehistory -
account:otheruser@contoso.com
```

Output:

```PowerShell
/type: windows.data.settings.settingsusagehistory

[
{"Data":{"pageUsages":{"\"SettingsPageAppsNotifications\"":{"Data":
{"frequency":1,"lastUsedTime":1.3353819570909629E+17,"lastUsedSettingId":"Sy
stemSettings_Notifications_QuietHours_MuteNotification_Enabled"}},"\"Setting
sPageOtherUsers\"":{"Data":
{"frequency":1,"lastUsedTime":1.3353709031552022E+17,"lastUsedSettingId":"Sy
stemSettings.UserAccountsHandlers.RemoveOtherUserSetting"}}}}}
]
```

Multi-instance type with collection name

Command line:

```PowerShell
readclouddatasettings.exe enum -type:windows.data.wifi.wifiprofile -
collection:wificloudstore3
```

Output:

```PowerShell
/type: windows.data.wifi.wifiprofile
/collection: wificloudstore3

[
    {"Data":{"profileXml":"<?xml version=\"1.0\"?>\r\n<WLANProfile

```

Note on serialization

For interoperability settings data structures are serialized to JSON when exported from Windows. In some cases, this can result in unintuitive results. See the examples below.

Basic data types

Basic data types (integer, floating point, string, etc) have no special representation beyond normal JSON encoding.

Structures

All structures (including top level structures) are wrapped in a JSON element called "Data". This includes nested structures (including when structures are used in vectors, maps, and nullables)

Example

This structure definition:

C#

```
struct MyInnerDataType
{
    0: int32 data;
}

struct MyDataType
{
    0: MyInnerDataType innerData;
    1: int64 id;
}
```

Becomes the following JSON:

JSON

```
{
    "Data":
    {
        "innerData":
        {
            "Data":
            {
                "data": 1
            }
        },
        "id": 2
    }
}
```

Vectors / Lists

Vectors and lists are translated into standard JSON arrays (with the caveat from above that a list of structures has each element wrapped in a JSON element named "Data").

Example

This structure definition:

C#

```
struct MyInnerDataType
{
    0: int32 data;
}

struct MyDataType
{
    0: vector<MyInnerDataType> dataList;
    1: vector<int32> idList;
}
```

Becomes the following JSON:

JSON

```
{
    "Data":
    {
        "dataList":
        [
            {
                "Data":
                {
                    "data": 1
                }
            },
            {
                "Data":
                {
                    "data": 2
                }
            },
        ],
        "idList": [ 1, 2 ]
    }
}
```

Blob

Blobs are translated into arrays of integers

Example

This structure definition:

C#

```
Struct mySetting
{
0: blob settingData;
}
```

Becomes the following JSON:

JSON

```
{
    "Data":
    {
        "settingData":
[-103,84,-51,60,-88,-121,16,75,-94,21,96,-120,-120,-35,59,85,4,0,0,0,0,1,0,0

Devices and sensors

Article • 10/22/2021

This article provides an index of development features that are related to scenarios involving devices and sensors in Windows apps.

> **Note**
>
> The **Windows App SDK** currently does not provide APIs related to devices and sensors scenarios.

Windows OS features

Windows 10 and later OS releases provide a wide variety of APIs related to data and files scenarios for apps. These features are available via a combination of WinRT and Win32 (C++ and COM) APIs provided by the Windows SDK.

WinRT APIs

The following articles provide information about features available via WinRT APIs provided by the Windows SDK.

Article	Description
Devices, sensors, and power	Learn about the breadth of features available for integrating external devices and sensors into your app.
Enumerate devices	Learn how to find devices that are internally connected to the system, externally connected, or detectable over wireless or networking protocols.
Sensors	Learn how to access sensors such as accelerometers, compasses, and gyrometers.
Bluetooth	Learn how to integrate classic Bluetooth (RFCOMM) and Bluetooth Low Energy (LE) into your apps.
Printing and scanning	Learn how to print and scan from your app.
3D printing	Learn how to add 3D printing functionality to your app.

Article	Description
Get battery information	Learn how to get detailed battery information, including the charge, capacity, and status of a battery or aggregate of batteries.

Win32 (C++ and COM) APIs

The following articles provide information about features available via Win32 (C++ and COM) APIs provided by the Windows SDK.

Article	Description
Sensor API	Learn how to access sensor data using Win32 APIs.
Printing	Learn how to print documents using Win32 APIs.
Power management	Learn how to access power management features using Win32 APIs.

.NET features

The .NET SDK also provides APIs related to device scenarios for WPF and Windows Forms apps.

Article	Description
Printing and print system management (WPF)	Learn how to print documents using .NET APIs for WPF apps.
Print support (Windows Forms)	Learn how to print documents using .NET APIs for Windows Forms apps.
Power management in Windows Forms	Learn how to access power management features using .NET APIs for Windows Forms apps.

Printing and scanning

Article • 09/11/2024

This section describes how to print and scan from your Windows app.

Expand table

Topic	Description
Print from your app	Learn how to print documents from a Windows app. This topic also shows how to print specific pages.
Customize the print preview UI	This section describes how to customize the print options and settings in the print preview UI.
Scan from your app	Learn here how to scan content from your app by using a flatbed, feeder, or auto-configured scan source.

Related topics

- UWP print sample
- Customize the print workflow

Print from your app

Article • 09/11/2024

This topic describes how to print from a Windows app.

For more advanced features, see Customize the print preview UI.

✓ **Important APIs**: Windows.Graphics.Printing namespace, PrintManager class, PrintTask, Microsoft.UI.Xaml.Printing namespace, PrintDocument class

Register for printing

The first step to add printing to your app is to register for printing by getting the PrintManager object for the current window. The PrintManager class is responsible for orchestrating the printing flow for your app. To use this class, you must first call the method that returns the PrintManager object that is specific to the current active window.

- In a non-UWP app, use the PrintManagerInterop.GetForWindow method.
- In a UWP app, use the PrintManager.GetForCurrentView method.

Your app must do this on every screen from which you want your user to be able to print. Only the screen that is displayed to the user can be registered for printing. If one screen of your app has registered for printing, it must unregister for printing when it exits. If it is replaced by another screen, the next screen must register for printing when it opens.

> **Tip**
>
> If you need to support printing from more than one page in your app, you can put this print code in a common helper class and have your app pages reuse it. For an example of how to do this, see the `PrintHelper` class in the **UWP print sample**.

After a user has initiated printing, you use a PrintDocument to prepare the pages to be sent to the printer.The `PrintDocument` type is in the **Microsoft.UI.Xaml.Printing** namespace along with other types that support preparing XAML content for printing.

The PrintDocument class is used to handle much of the interaction between the app and the PrintManager, but it exposes several callbacks of its own. During registration, create instances of `PrintManager` and `PrintDocument` and register handlers for their printing events.

In this example, registration is performed in the `RegisterForPrinting` method, which is called from the page's Loaded event handler.

C#

```
using Microsoft.UI.Xaml.Printing;
using Windows.Graphics.Printing;

PrintDocument printDocument = null;
IPrintDocumentSource printDocumentSource = null;
List<UIElement> printPreviewPages = new List<UIElement>();

private void MainPage_Loaded(object sender, RoutedEventArgs e)
{
    RegisterForPrinting();
}

private void RegisterForPrinting()
{
    var hWnd = WinRT.Interop.WindowNative.GetWindowHandle(App.MainWindow);
    PrintManager printManager = PrintManagerInterop.GetForWindow(hWnd);
    printManager.PrintTaskRequested += PrintTask_Requested;

    printDocument = new PrintDocument();
    printDocumentSource = printDocument.DocumentSource;
    printDocument.Paginate += PrintDocument_Paginate;
    printDocument.GetPreviewPage += PrintDocument_GetPreviewPage;
    printDocument.AddPages += PrintDocument_AddPages;
}
```

> **⚠ Warning**
>
> In UWP printing examples, it's recommended to register for printing from the OnNavigatedTo method override. In non-UWP apps, you need to use the window handle in the PrintManagerInterop.GetForWindow call, so you should use the Loaded event to ensure that the window handle is not `null`, which might be the case in OnNavigatedTo.

Here, the event handlers are unregistered in the `UnregisterForPrinting` method, which is called from the OnNavigatedFrom method.

C#

```
protected override void OnNavigatedFrom(NavigationEventArgs e)
{
    base.OnNavigatedFrom(e);
    UnregisterForPrinting();
}
```

```
private void UnregisterForPrinting()
{
    if (printDocument == null)
    {
        return;
    }

    printDocument.Paginate -= PrintDocument_Paginate;
    printDocument.GetPreviewPage -= PrintDocument_GetPreviewPage;
    printDocument.AddPages -= PrintDocument_AddPages;

    var hWnd = WinRT.Interop.WindowNative.GetWindowHandle(App.MainWindow);
    PrintManager printManager = PrintManagerInterop.GetForWindow(hWnd);
    printManager.PrintTaskRequested -= PrintTask_Requested;
}
```

> **Note**
>
> If you have a multiple-page app and don't disconnect printing, an exception is thrown when the user leaves the page and then returns to it.

Create a print button

Add a print button to your app's screen where you'd like it to appear. Make sure that it doesn't interfere with the content that you want to print.

XAML

```
<Button x:Name="InvokePrintingButton"
        Content="Print"
        Click="InvokePrintingButton_Click"/>
```

In the Button's Click event handler, show the Windows print UI to the user.

- In a non-UWP app, use the PrintManagerInterop.ShowPrintUIForWindowAsync method.
- In a UWP app, use the PrintManager.ShowPrintUIAsync method.

C#

```
var hWnd = WinRT.Interop.WindowNative.GetWindowHandle(App.MainWindow);
await PrintManagerInterop.ShowPrintUIForWindowAsync(hWnd);
```

This method is an asynchronous method that displays the appropriate printing window, so you'll need to add the async keyword to the Click handler. We recommend calling the IsSupported method first in order to check that the app is being run on a device that supports printing (and handle the case in which it is not). If printing can't be performed at that time for any other reason, the method will throw an exception. We recommend catching these exceptions and letting the user know when printing can't proceed.

In this example, a print window is displayed in the event handler for a button click. If the method throws an exception (because printing can't be performed at that time), a ContentDialog control informs the user of the situation.

C#

```
private async void InvokePrintingButton_Click(object sender, RoutedEventArgs
e)
{
    if (PrintManager.IsSupported())
    {
        try
        {
            // Show system print UI.
            var hWnd =
WinRT.Interop.WindowNative.GetWindowHandle(App.MainWindow);
            await
Windows.Graphics.Printing.PrintManagerInterop.ShowPrintUIForWindowAsync(hWnd
);
        }
        catch
        {
            // Printing cannot proceed at this time.
            ContentDialog noPrintingDialog = new ContentDialog()
            {
                Title = "Printing error",
                Content = "\nSorry, printing can' t proceed at this time.",
                PrimaryButtonText = "OK"
            };
            await noPrintingDialog.ShowAsync();
        }
    }
    else
    {
        // Printing is not supported on this device.
        ContentDialog noPrintingDialog = new ContentDialog()
        {
            Title = "Printing not supported",
            Content = "\nSorry, printing is not supported on this device.",
            PrimaryButtonText = "OK"
        };
        await noPrintingDialog.ShowAsync();
```

```
    }
}
```

Format your app's content

When `ShowPrintUIForWindowAsync` is called, the PrintTaskRequested event is raised. In the `PrintTaskRequested` event handler, you create a PrintTask by calling the PrintTaskRequest.CreatePrintTask method. Pass the title for the print page and the name of a PrintTaskSourceRequestedHandler delegate. The title is shown in the print preview UI. The `PrintTaskSourceRequestedHandler` links the `PrintTask` with the `PrintDocument` that will provide the content.

In this example, a completion handler is also defined to catch errors. It's a good idea to handle completion events because then your app can let the user know if an error occurred and provide possible solutions. Likewise, your app could use the completion event to indicate subsequent steps for the user to take after the print job is successful.

C#

```
private void PrintTask_Requested(PrintManager sender,
PrintTaskRequestedEventArgs args)
{
    // Create the PrintTask.
    // Defines the title and delegate for PrintTaskSourceRequested.
    PrintTask printTask = args.Request.CreatePrintTask("WinUI 3 Printing
example", PrintTaskSourceRequested);

    // Handle PrintTask.Completed to catch failed print jobs.
    printTask.Completed += PrintTask_Completed;

    DispatcherQueue.TryEnqueue(DispatcherQueuePriority.Normal, () =>
    {
        InvokePrintingButton.IsEnabled = false;
    });
}

private void PrintTaskSourceRequested(PrintTaskSourceRequestedArgs args)
{
    // Set the document source.
    args.SetSource(printDocumentSource);
}

private void PrintTask_Completed(PrintTask sender,
PrintTaskCompletedEventArgs args)
{
    string StatusBlockText = string.Empty;

    // Notify the user if the print operation fails.
```

```
    if (args.Completion == PrintTaskCompletion.Failed)
    {
        StatusBlockText = "Failed to print.";
    }
    else if (args.Completion == PrintTaskCompletion.Canceled)
    {
        StatusBlockText = "Printing canceled.";
    }
    else
    {
        StatusBlockText = "Printing completed.";
    }

    DispatcherQueue.TryEnqueue(DispatcherQueuePriority.Normal, () =>
    {
        StatusBlock.Text = StatusBlockText;
        InvokePrintingButton.IsEnabled = true;
    });
}
```

After the print task is created, the PrintManager requests a collection of print pages to show in the print preview UI by raising the Paginate event. (This corresponds with the `Paginate` method of the `IPrintPreviewPageCollection` interface.) The event handler you created during registration is called at this time.

> **ⓘ Important**
>
> If the user changes print settings, the paginate event handler will be called again to allow you to reflow the content. For the best user experience, we recommend checking the settings before you reflow the content and avoid reinitializing the paginated content when it's not necessary.

In the Paginate event handler, create the pages to show in the print preview UI and to send to the printer. The code you use to prepare your app's content for printing is specific to your app and the content you print.

This example shows the basic steps to create a single print page that prints an image and caption from the page shown on the screen.

- Create a list to hold the UI elements (pages) to be printed.
- Clear the list of preview pages so that pages aren't duplicated each time pagination occurs.
- Use the PrintPageDescription to get the size of the printer page.
- Format your XAML content to fit the printer page. Each page to be printed is a XAML UI element (typically a container element that contains other content). In

this example, elements are created in code and use the same data as the elements shown on the screen.

- Flow the content onto additional pages as needed. Multiple pages are not shown in this basic example, but dividing the content into pages is an important part of the Paginate event.
- Add each page to the list of pages to print.
- Set the count of preview pages on the PrintDocument.

C#

```
List<UIElement> printPreviewPages = new List<UIElement>();

private void PrintDocument_Paginate(object sender, PaginateEventArgs e)
{
    // Clear the cache of preview pages.
    printPreviewPages.Clear();

    // Get the PrintTaskOptions.
    PrintTaskOptions printingOptions =
((PrintTaskOptions)e.PrintTaskOptions);
    // Get the page description to determine the size of the print page.
    PrintPageDescription pageDescription =
printingOptions.GetPageDescription(0);

    // Create the print layout.
    StackPanel printLayout = new StackPanel();
    printLayout.Width = pageDescription.PageSize.Width;
    printLayout.Height = pageDescription.PageSize.Height;
    printLayout.BorderBrush = new
Microsoft.UI.Xaml.Media.SolidColorBrush(Microsoft.UI.Colors.Black);
    printLayout.BorderThickness = new Thickness(48);

    Image printImage = new Image();
    printImage.Source = printContent.Source;

    printImage.Width = pageDescription.PageSize.Width / 2;
    printImage.Height = pageDescription.PageSize.Height / 2;

    TextBlock imageDescriptionText = new TextBlock();
    imageDescriptionText.Text = imageDescription.Text;
    imageDescriptionText.FontSize = 24;
    imageDescriptionText.HorizontalAlignment = HorizontalAlignment.Center;
    imageDescriptionText.Width = pageDescription.PageSize.Width / 2;
    imageDescriptionText.TextWrapping = TextWrapping.WrapWholeWords;

    printLayout.Children.Add(printImage);
    printLayout.Children.Add(imageDescriptionText);

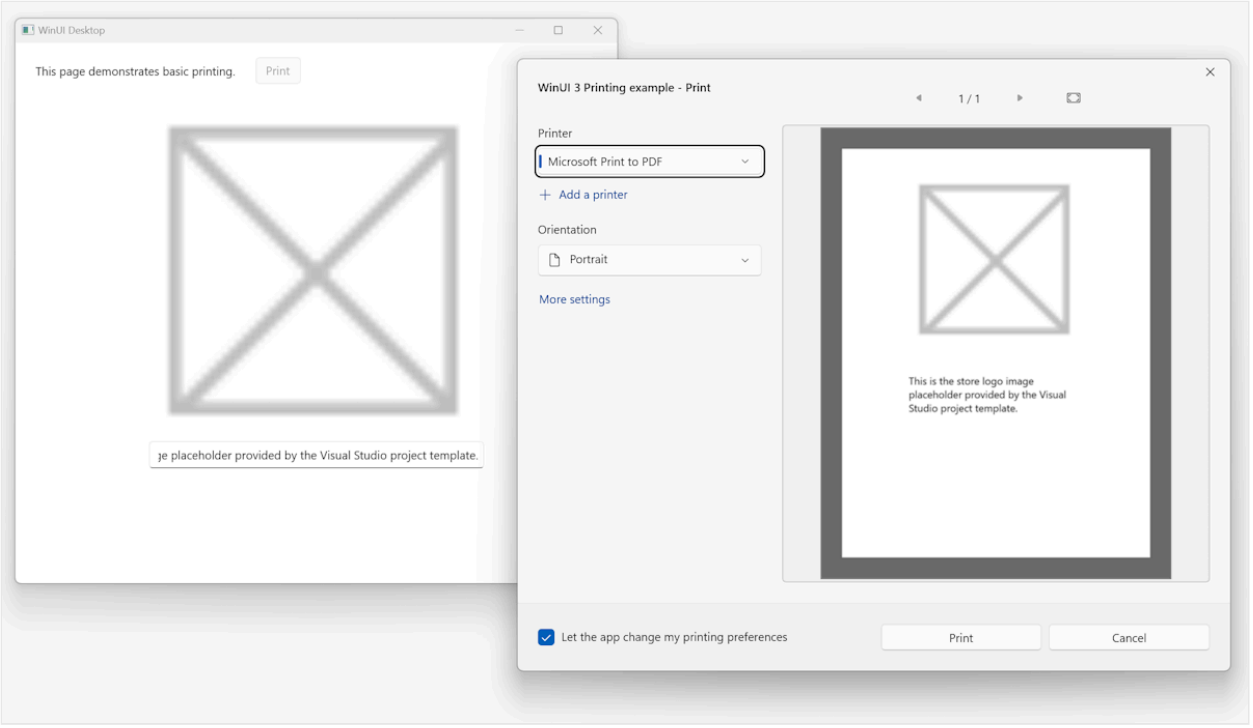
    // Add the print layout to the list of preview pages.
    printPreviewPages.Add(printLayout);

    // Report the number of preview pages created.
```

```
    PrintDocument printDocument = (PrintDocument)sender;
    printDocument.SetPreviewPageCount(printPreviewPages.Count,

PreviewPageCountType.Intermediate);
}
```

Here's a screenshot of the app UI and how the content appears in the print preview UI.



When a particular page is to be shown in the print preview window, the PrintManager raises the GetPreviewPage event. This corresponds with the `MakePage` method of the `IPrintPreviewPageCollection` interface. The event handler you created during registration is called at this time.

In the GetPreviewPage event handler, set the appropriate page on the print document.

C#

```
private void PrintDocument_GetPreviewPage(object sender,
GetPreviewPageEventArgs e)
{
    PrintDocument printDocument = (PrintDocument)sender;
    printDocument.SetPreviewPage(e.PageNumber,
printPreviewPages[e.PageNumber - 1]);
}
```

Finally, once the user clicks the print button, the PrintManager requests the final collection of pages to send to the printer by calling the `MakeDocument` method of the

`IDocumentPageSource` interface. In XAML, this raises the AddPages event. The event handler you created during registration is called at this time.

In the AddPages event handler, add pages from the page collection to the PrintDocument object to be sent to the printer. If a user specifies particular pages or a range of pages to print, you use that information here to add only the pages that will actually be sent to the printer.

C#

```
private void PrintDocument_AddPages(object sender, AddPagesEventArgs e)
{
    PrintDocument printDocument = (PrintDocument)sender;

    // Loop over all of the preview pages and add each one to be printed.
    for (int i = 0; i < printPreviewPages.Count; i++)
    {
        printDocument.AddPage(printPreviewPages[i]);
    }

    // Indicate that all of the print pages have been provided.
    printDocument.AddPagesComplete();
}
```

Customize the print preview UI

Article • 09/11/2024

This topic describes how to customize the print options and settings in the print preview UI. For more info about printing, see Print from your app.

- ✓ **Important APIs**: Windows.Graphics.Printing namespace, PrintTask, StandardPrintTaskOptions class, Microsoft.UI.Xaml.Printing namespace, PrintDocument class

Customize print options

By default, the print preview UI shows the **ColorMode**, **Copies**, and **Orientation** print options. In addition to those, there are several other common printer options that you can add to the print preview UI:

- **Binding**
- **Bordering**
- **Collation**
- **CustomPageRanges**
- **Duplex**
- **HolePunch**
- **InputBin**
- **MediaSize**
- **MediaType**
- **NUp**
- **PrintQuality**
- **Staple**

These options are defined in the StandardPrintTaskOptions class. You can add to or remove options from the list of options displayed in the print preview UI. You can also change the order in which they appear, and set the default settings that are shown to the user.

However, the modifications that you make in this way affect only the print preview UI. The user can always access all of the options that the printer supports by tapping **More settings** in the print preview UI.

Define the options to display

When you register your app for printing (see Print from your app), part of that registration includes defining the PrintTaskRequested event handler. The code to customize the options displayed in the print preview UI is added to the PrintTaskRequested event handler.

After you create the PrintTask in the PrintTaskRequested event handler , you can get the DisplayedOptions list, which contains the option items shown in the print preview UI. You can modify this list by inserting, appending, removing, or re-ordering options.

> **Note**
>
> Although your app can specify any print options to be displayed, only those that are supported by the selected printer are shown in the print preview UI. The print UI won't show options that the selected printer doesn't support.

C#

```
private void PrintTask_Requested(PrintManager sender,
PrintTaskRequestedEventArgs args)
{
    // Create the PrintTask.
    // Defines the title and delegate for PrintTaskSourceRequested.
    PrintTask printTask = args.Request.CreatePrintTask("WinUI 3 Printing
example", PrintTaskSourceRequested);

    // Handle PrintTask.Completed to catch failed print jobs.
    printTask.Completed += PrintTask_Completed;

    DispatcherQueue.TryEnqueue(DispatcherQueuePriority.Normal, () =>
    {
        InvokePrintingButton.IsEnabled = false;
    });

    // Customize options displayed in print preview UI.
    // Get the list of displayed options.
    IList<string> displayedOptions = printTask.Options.DisplayedOptions;

    // Choose the printer options to be shown.
    // The order in which the options are appended determines
    // the order in which they appear in the UI.
    displayedOptions.Clear();
    displayedOptions.Add(StandardPrintTaskOptions.Copies);
    displayedOptions.Add(StandardPrintTaskOptions.Orientation);
    displayedOptions.Add(StandardPrintTaskOptions.MediaSize);
    displayedOptions.Add(StandardPrintTaskOptions.Collation);
    displayedOptions.Add(StandardPrintTaskOptions.Duplex);

    // Preset the default value of the print media size option.
```

```
    printTask.Options.MediaSize = PrintMediaSize.NorthAmericaLegal;
}
```

Specify default options

You can also set the default values of the options in the print preview UI. The following line of code, from the last example, sets the default value of the MediaSize option.

C#

```
// Preset the default value of the print media size option.
printTask.Options.MediaSize = PrintMediaSize.NorthAmericaLegal;
```

> **Note**
>
> When you set the values in the DisplayedOptions list, you use the name you get from StandardPrintTaskOptions (for example, StandardPrintTaskOptions.MediaSize).
>
> When you set the default value of an option, you use PrintTaskOptions (for example, PrintTaskOptions.MediaSize).

Add custom print options

Here, we demonstrate how to create a new custom print option, define a list of values that the option supports, and then add the option to the print preview. In this example, the custom print option lets the user specify whether to print only the text on the page, only the image, or both the text and image. The options are presented in a drop-down list.

In order to ensure a good user experience, the system requires that the app handle the PrintTaskRequested event within the time specified by PrintTaskRequestedEventArgs.Request.Deadline. Therefore, we use the PrintTaskRequested handler only to create the print task. The print settings customization can be done when the print document source is requested. Here, we use a lambda expression to define the PrintTaskSourceRequestedHandler inline, which provides easier access to the PrintTask.

First, get a PrintTaskOptionDetails object and its list of DisplayedOptions. You use this to add the new print option to the print preview UI.

Next, to present the custom print options in a drop-down list, call PrintTaskOptionDetails.CreateItemListOption to create a PrintCustomItemListOptionDetails object. Create the new print option and initialize the list of option values. Finally, add the new option to the DisplayedOptions list and assign a handler for the OptionChanged event. Because you are just adding a new print option at the end of the list of default options, you don't need to clear the DisplayedOptions list; just add the new option.

C#

```
private void PrintTask_Requested(PrintManager sender,
PrintTaskRequestedEventArgs args)
{
    // Create the PrintTask.
    PrintTask printTask = null;
    printTask = args.Request.CreatePrintTask("WinUI 3 Printing example",
sourceRequestedArgs =>
    {
        PrintTaskSourceRequestedDeferral deferral =
            sourceRequestedArgs.GetDeferral();
        PrintTaskOptionDetails printDetailedOptions =

PrintTaskOptionDetails.GetFromPrintTaskOptions(printTask.Options);
        IList<string> displayedOptions =
printDetailedOptions.DisplayedOptions;

        // Create a new list option.
        PrintCustomItemListOptionDetails pageFormat =
            printDetailedOptions.CreateItemListOption("PageContent", "Page
content");
        pageFormat.AddItem("PicturesText", "Pictures and text");
        pageFormat.AddItem("PicturesOnly", "Pictures only");
        pageFormat.AddItem("TextOnly", "Text only");

        // Add the custom option to the option list
        displayedOptions.Add("PageContent");

        printDetailedOptions.OptionChanged +=
PrintDetailedOptions_OptionChanged;
        sourceRequestedArgs.SetSource(printDocumentSource);

        deferral.Complete();
    });

    // Handle PrintTask.Completed to catch failed print jobs.
    printTask.Completed += PrintTask_Completed;

    DispatcherQueue.TryEnqueue(DispatcherQueuePriority.Normal, () =>
    {
        InvokePrintingButton.IsEnabled = false;
```

```
    });
}
```

The options appear in the print preview UI in the same order they are appended, with the first option shown at the top of the window. In this example, the custom option is appended last so that it appears at the bottom of the list of options. However, you could put it anywhere in the list; custom print options don't need to be added last.

When the user changes the selected option in your custom option, use the selected option to update the print preview image. After the print preview layout in updated, call the InvalidatePreview method to redraw the image in the print preview UI, as shown here.

C#

```
void PrintDetailedOptions_OptionChanged(PrintTaskOptionDetails sender,
                                        PrintTaskOptionChangedEventArgs
args)
{
    string optionId = args.OptionId as string;
    if (string.IsNullOrEmpty(optionId))
    {
        return;
    }

    if (optionId == "PageContent")
    {
        PrintCustomItemListOptionDetails pageContentOption =
            (PrintCustomItemListOptionDetails)sender.Options["PageContent"];
        string pageContentValue = pageContentOption.Value.ToString();

        if (pageContentValue == "PicturesOnly")
        {
            pageLayoutOption = PageLayoutOption.Images;
        }
        else if (pageContentValue == "TextOnly")
        {
            pageLayoutOption = PageLayoutOption.Text;
        }
        else
        {
            pageLayoutOption = PageLayoutOption.TextAndImages;
        }

        DispatcherQueue.TryEnqueue(DispatcherQueuePriority.Normal, () =>
        {
            printDocument.InvalidatePreview();
        });
    }
}
```

To support use of the custom options in your page, add an enum for the available options and a page-level variable to hold the selected option.

C#

```
internal enum PageLayoutOption : int
{
    Text = 1,
    Images = 2,
    TextAndImages = 3
}

PageLayoutOption pageLayoutOption = PageLayoutOption.TextAndImages;
```

Then, use the selected option in your Paginate handler where you add the content for the print preview.

C#

```
private void PrintDocument_Paginate(object sender, PaginateEventArgs e)
{
    // Clear the cache of preview pages.
    printPreviewPages.Clear();

    // Get the PrintTaskOptions.
    PrintTaskOptions printingOptions =
((PrintTaskOptions)e.PrintTaskOptions);
    // Get the page description to determine the size of the print page.
    PrintPageDescription pageDescription =
printingOptions.GetPageDescription(0);

    // Create the print layout.
    StackPanel printLayout = new StackPanel();
    printLayout.Width = pageDescription.PageSize.Width;
    printLayout.Height = pageDescription.PageSize.Height;
    printLayout.BorderBrush = new
Microsoft.UI.Xaml.Media.SolidColorBrush(Microsoft.UI.Colors.DimGray);
    printLayout.BorderThickness = new Thickness(48);

    // Use the custom print layout options to determine
    // which elements to add to the print page.
    if (pageLayoutOption == PageLayoutOption.Images ||
        pageLayoutOption == PageLayoutOption.TextAndImages)
    {
        Image printImage = new Image();
        printImage.Source = printContent.Source;

        printImage.Width = pageDescription.PageSize.Width / 2;
        printImage.Height = pageDescription.PageSize.Height / 2;
        printLayout.Children.Add(printImage);
    }
```

```
    if (pageLayoutOption == PageLayoutOption.Text ||
        pageLayoutOption == PageLayoutOption.TextAndImages)
    {
        TextBlock imageDescriptionText = new TextBlock();
        imageDescriptionText.Text = imageDescription.Text;
        imageDescriptionText.FontSize = 24;
        imageDescriptionText.HorizontalAlignment =
HorizontalAlignment.Center;
        imageDescriptionText.Width = pageDescription.PageSize.Width / 2;
        imageDescriptionText.TextWrapping = TextWrapping.WrapWholeWords;

        printLayout.Children.Add(imageDescriptionText);
    }

    // Add the print layout to the list of preview pages.
    printPreviewPages.Add(printLayout);

    // Report the number of preview pages created.
    PrintDocument printDocument = (PrintDocument)sender;
    printDocument.SetPreviewPageCount(printPreviewPages.Count,

PreviewPageCountType.Intermediate);
}
```

Scan from your app

Article • 09/11/2024

This topic describes how to scan content from your app by using a flatbed, feeder, or auto-configured scan source.

Important APIs

- Windows.Devices.Scanners
- DeviceInformation
- DeviceClass

To scan from your app, you must first list the available scanners by declaring a new DeviceInformation object and getting the DeviceClass type. Only scanners that are installed locally with WIA drivers are listed and available to your app.

After your app has listed available scanners, it can use the auto-configured scan settings based on the scanner type, or just scan using the available flatbed or feeder scan source. To use auto-configured settings, the scanner must be enabled for auto-configuration and must not be equipped with both a flatbed and a feeder scanner. For more info, see Auto-Configured Scanning.

Enumerate available scanners

Windows does not detect scanners automatically. You must perform this step in order for your app to communicate with the scanner. In this example, the scanner device enumeration is done using the Windows.Devices.Enumeration namespace.

1. First, add these using statements to your class definition file.

C#

```
using Windows.Devices.Enumeration;
using Windows.Devices.Scanners;
```

2. Next, implement a device watcher to start enumerating scanners. For more info, see Enumerate devices.

C#

```
void InitDeviceWatcher()
{
   // Create a Device Watcher class for type Image Scanner for
```

```
enumerating scanners
        scannerWatcher =
DeviceInformation.CreateWatcher(DeviceClass.ImageScanner);

        scannerWatcher.Added += OnScannerAdded;
        scannerWatcher.Removed += OnScannerRemoved;
        scannerWatcher.EnumerationCompleted += OnScannerEnumerationComplete;
    }
```

3. Create an event handler for when a scanner is added.

C#

```
    private async void OnScannerAdded(DeviceWatcher sender,
DeviceInformation deviceInfo)
    {
        await
        MainPage.Current.Dispatcher.RunAsync(
              Windows.UI.Core.CoreDispatcherPriority.Normal,
              () =>
              {
                 MainPage.Current.NotifyUser(String.Format("Scanner with
device id {0} has been added", deviceInfo.Id), NotifyType.StatusMessage);

                 // search the device list for a device with a matching
device id
                 ScannerDataItem match = FindInList(deviceInfo.Id);

                 // If we found a match then mark it as verified and return
                 if (match != null)
                 {
                    match.Matched = true;
                    return;
                 }

                 // Add the new element to the end of the list of devices
                 AppendToList(deviceInfo);
              }
        );
    }
```

Scan

1. **Get an ImageScanner object**

For each ImageScannerScanSource enumeration type, whether it's **Default**, **AutoConfigured**, **Flatbed**, or **Feeder**, you must first create an ImageScanner object by calling the ImageScanner.FromIdAsync method, like this.

```
C#

   ImageScanner myScanner = await ImageScanner.FromIdAsync(deviceId);
```

2. **Just scan**

To scan with the default settings, your app relies on the **Windows.Devices.Scanners** namespace to select a scanner and scans from that source. No scan settings are changed. The possible scanners are auto-configure, flatbed, or feeder. This type of scan will most likely produce a successful scan operation, even if it scans from the wrong source, like flatbed instead of feeder.

Note If the user places the document to scan in the feeder, the scanner will scan from the flatbed instead. If the user tries to scan from an empty feeder, the scan job won't produce any scanned files.

```
C#

    var result = await
myScanner.ScanFilesToFolderAsync(ImageScannerScanSource.Default,
        folder).AsTask(cancellationToken.Token, progress);
```

3. **Scan from Auto-configured, Flatbed, or Feeder source**

Your app can use the device's Auto-Configured Scanning to scan with the most optimal scan settings. With this option, the device itself can determine the best scan settings, like color mode and scan resolution, based on the content being scanned. The device selects the scan settings at run time for each new scan job.

Note Not all scanners support this feature, so the app must check if the scanner supports this feature before using this setting.

In this example, the app first checks if the scanner is capable of auto-configuration and then scans. To specify either flatbed or feeder scanner, simply replace **AutoConfigured** with **Flatbed** or **Feeder**.

```
C#

    if
(myScanner.IsScanSourceSupported(ImageScannerScanSource.AutoConfigured))
    {
        ...
        // Scan API call to start scanning with Auto-Configured settings.
        var result = await myScanner.ScanFilesToFolderAsync(
            ImageScannerScanSource.AutoConfigured,
folder).AsTask(cancellationToken.Token, progress);
```

```
        ...
    }
```

Preview the scan

You can add code to preview the scan before scanning to a folder. In the example below, the app checks if the **Flatbed** scanner supports preview, then previews the scan.

C#

```
if (myScanner.IsPreviewSupported(ImageScannerScanSource.Flatbed))
{
    rootPage.NotifyUser("Scanning", NotifyType.StatusMessage);
                // Scan API call to get preview from the flatbed.
                var result = await myScanner.ScanPreviewToStreamAsync(
                    ImageScannerScanSource.Flatbed, stream);
```

Cancel the scan

You can let users cancel the scan job midway through a scan, like this.

C#

```
void CancelScanning()
{
    if (ModelDataContext.ScenarioRunning)
    {
        if (cancellationToken != null)
        {
            cancellationToken.Cancel();
        }
        DisplayImage.Source = null;
        ModelDataContext.ScenarioRunning = false;
        ModelDataContext.ClearFileList();
    }
}
```

Scan with progress

1. Create a **System.Threading.CancellationTokenSource** object.

C#

```
cancellationToken = new CancellationTokenSource();
```

2. Set up the progress event handler and get the progress of the scan.

```
C#
```

```
    rootPage.NotifyUser("Scanning", NotifyType.StatusMessage);
    var progress = new Progress<UInt32>(ScanProgress);
```

Scanning to the pictures library

Users can scan to any folder dynamically using the **FolderPicker** class, but you must declare the *Pictures Library* capability in the manifest to allow users to scan to that folder. For more info on app capabilities, see App capability declarations.

Graphics

Article • 05/25/2023

This article provides an index of development features that are related to scenarios involving graphics in Windows apps.

Win2D

Win2D is an easy-to-use Windows Runtime API for immediate mode 2D graphics rendering with GPU acceleration.

Windows App SDK features

The Windows App SDK provides the following features related to graphics scenarios for Windows 10 and later OS releases.

Expand table

Feature	Description
Render text with DWriteCore	Use the C++/COM APIs in the DWriteCore headers of the Windows App SDK to render text using a device-independent text layout system, high quality sub-pixel Microsoft ClearType text rendering, hardware-accelerated text, multi-format text, wide language support, and much more.

Windows OS features

Windows 10 and later OS releases provide a wide variety of APIs related to graphics scenarios for apps. These features are available via a combination of WinRT and Win32 (C++ and COM) APIs provided by the Windows SDK.

WinRT APIs

The following articles provide information about features available via WinRT APIs provided by the Windows SDK.

Enhance UI with the Visual layer (Windows App SDK/WinUI 3)

Article • 08/19/2024

The Visual layer in the Windows App SDK/WinUI 3 provides a high performance, retained-mode API for graphics, effects, animations, and input. It's the foundation for all UI across Windows devices.

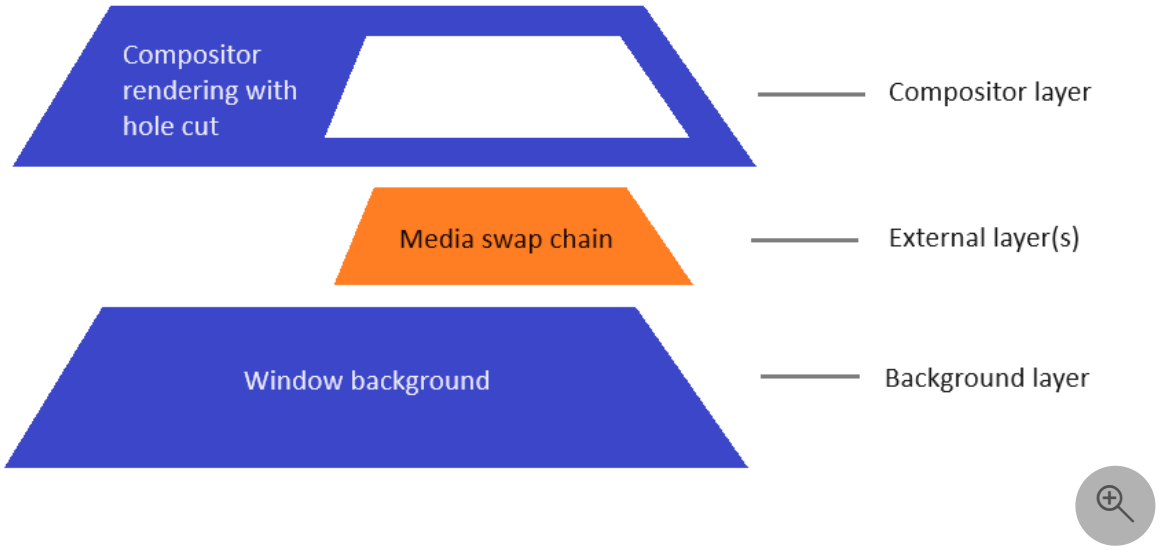
The types in Microsoft.UI.Composition form the Windows App SDK/WinUI 3 implementation of the Visual layer. It's very similar to the UWP Visual layer, which is implemented in the **Windows.UI.Composition** namespace. The differences between the two and the missing functionality from the Windows App SDK/WinUI 3 Visual layer are detailed below.

Differences from UWP

The most obvious difference between **Microsoft.UI.Composition** and the UWP Visual layer is the namespace. **Microsoft.UI.Composition** provides access to functionality that's nearly identical to that of the UWP Visual layer, in the most commonly used scenarios. But there are exceptions, and differences.

The Windows App SDK/WinUI 3 uses **Microsoft.UI.Composition** to describe a tree of individual Visuals. Those Visuals are then composited to create the complete rendering of the window. It's very similar to how **Windows.UI.Composition** works (for UWP apps). But one big difference is that the **Microsoft.UI.Composition** compositor runs entirely within a Windows App SDK app; and it has access only to pixels that it drew. That means that any *external* content (content that wasn't drawn by the compositor) is unknown to the compositor. Which creates certain limitations.

An example of external content is the (**Microsoft.UI.Xaml.Controls**) MediaPlayerElement. The Windows media stack provides to XAML an opaque media swap chain handle. XAML gives that handle to the compositor, which in turn hands it off to Windows (via **Windows.UI.Composition**) to display. More specifically, since the compositor can't see any of the pixels in the media swap chain, it can't composite that as part of the overall rendering for the window. Instead, it gives the media swap chain to Windows to render it below the compositor's rendering, with a hole cut out of the compositor's rendering in order to allow the media swap chain below it to be visible. Here's a visualization of this setup.



In general, the approach allows external content (such as swap chains) to be part of the overall rendering for the window; and it still allows other content drawn by the compositor to overlap on top of the external content—for example, XAML's MediaTransportControls rendering on top of the media. But it doesn't allow more advanced effect interactions with this external content. That applies to all approaches that one could use to plug a swap chain into a view: either via XAML (for example, via SwapChainPanel), or via Composition (for example, using ICompositorInterop::CreateCompositionSurfaceForSwapChain).

In the Windows App SDK/WinUI 3, the following APIs all create external content.

- MediaPlayerElement
- SwapChainPanel
- WebView2
- MicaBackdrop and DesktopAcrylicBackdrop, as well as the underlying MicaController and DesktopAcrylicController that they use.

The model, described above, of handling external content creates these limitations:

- It's not possible to have compositor content behind external content (that is, behind/below the external layer(s) in the diagram above). So, for example, it's not possible to give a **WebView2** a transparent background in order to be able to see XAML buttons or images behind it. The only things that can be behind external content are *other* external content and the window background. Because of that, we discourage/disable transparency for external content.
- It's not possible to have compositor content sample from external content. For example, AcrylicBrush isn't able to sample and blur any pixels from a **MediaPlayerElement**. **AcrylicBrush** will sample from the compositor's image, which

is transparent black for external content areas. So that transparent black will be what **AcrylicBrush** blurs. Similarly, **AcrylicBrush** in front of a **MicaBackdrop** or **DesktopAcrylicBackdrop** can't see any colors that those backdrops will draw; and instead, the brush will blur the transparent black.

- Another scenario is known as *destination invert*, which is used for the caret of text box controls to invert the pixels that the text insertion caret is in front of. That invert similarly samples from the compositor surface, and it will be impacted if the text box doesn't have an opaque background that's drawn by the compositor.
- Because the WinUI 3 SwapChainPanel creates external content, it doesn't support transparency. Nor does it support applying AcrylicBrush and other effects that use a CompositionBackdropBrush in front of it. **AcrylicBrush** and these other **CompositionBackdropBrush**-based effects are not able to sample from a **SwapChainPanel**.
- In desktop apps (a WinUI 3 app is a desktop app), **Window.Current** is `null`. So you can't retrieve an instance of Compositor from `Window.Current.Compositor`. In XAML apps (both WinUI 3 and UWP), we recommend that you call ElementCompositionPreview.GetElementVisual(UIElement) to get a Composition Visual, and retrieve the `Compositor` from the visual's Compositor property. In cases where you don't have access to a **UIElement** (for example, if you create a CompositionBrush in a class library), you can call CompositionTarget.GetCompositorForCurrentThread.

For more details about the Visual layer, see the Visual layer overview in the UWP documentation. In most cases, the documentation and samples are also applicable to **Microsoft.UI.Composition**.

Prerequisites to using Microsoft.UI.Composition

To use **Microsoft.UI.Composition** APIs in the Windows App SDK/WinUI 3:

1. Download and install the latest release of the Windows App SDK. For more information, see Start developing Windows apps.
2. Create a new project as described in Start developing Windows apps, or follow the instructions to use the Windows App SDK in an existing project.

To learn more about the availability of **Microsoft.UI.Composition** in the Windows App SDK/WinUI 3, see release channels.

Windows Composition Samples Gallery

We've updated the Windows Composition Samples Gallery to now take a dependency on the Windows App SDK Composition APIs. Visit WindowsCompositionSamples to see the Microsoft.UI.Composition APIs in action.

Render text with DWriteCore

Article • 08/21/2024

DWriteCore is the Windows App SDK implementation of DirectWrite (DirectWrite is the DirectX API for high-quality text rendering, resolution-independent outline fonts, and full Unicode text and layout support).

DWriteCore provides access to all current DirectWrite features for text rendering, including a device-independent text layout system, hardware-accelerated text, multi-format text, and wide language support.

For more details about DWriteCore—including guidance for setting up your development environment, and code examples for programming with it—see DWriteCore overview in the DirectWrite documentation.

Prerequisites to using DWriteCore

To use DWriteCore APIs in the Windows App SDK:

1. Download and install the latest release of the Windows App SDK. For more information, see Start developing Windows apps.
2. Create a new project as described in Start developing Windows apps, or follow the instructions to use the Windows App SDK in an existing project.

To learn more about the availability of DWriteCore in the Windows App SDK, see release channels.

Overview of Win2D

Article • 10/25/2023

Win2D is an easy-to-use Windows Runtime (WinRT) API for immediate-mode 2D graphics rendering with GPU acceleration. It's ideal for creating simple games, displays such as charts, and other simple 2D graphics.

You can use Win2D in your WinUI 3 (Windows App SDK) apps or Universal Windows Platform (UWP) apps, using either C#, C++, or VB. Win2D utilizes the power of Direct2D, and it integrates seamlessly with XAML on both WinUI 3 (Windows App SDK) and UWP.

> **ⓘ Important**
>
> Win2D for WinUI 3 (Windows App SDK) is a work-in-progress, and some features aren't supported. This documentation refers to both the WinUI 3 and UWP versions, which mostly share the same API surface and functionality. Whenever there's any relevant differences between the two, we'll call it out in the documentation. But otherwise, the info being presented applies to both platforms in the same way.

Get started

Win2D is available as a NuGet package, or as source code (for the source code, see the Win2D repo on GitHub).

Reference the Win2D NuGet package

In a WinUI 3 or UWP project in Visual Studio, click **Tools** > **NuGet Package Manager** > **Manage NuGet Packages for Solution...** > **Browse**. Make sure that **Include prerelease** is unchecked, and type or paste into the search box:

- For a WinUI 3 project, *Microsoft.Graphics.Win2D*.
- For a UWP project, *Win2D.uwp*.

Select the correct item in search results, check your project, and click **Install** to install the package into that project. Accept the license agreement.

> **ⓘ Important**
>
> If you see any error messages, then try updating the version of the Windows App SDK NuGet package that you're referencing (if appropriate). Or try going into

project properties, and setting **Target OS version** to the latest version.

Next steps

Next, to learn about creating a simple app, try out the Win2D "Hello, World!" quickstart, or the Build a simple Win2D app tutorial. You can also consult the features list to discover all the things Win2D can do. To learn more about advanced topics, you can refer to the collection of articles included in the documentation here as well.

The Win2D APIs.

Win2D "Hello, World!" quickstart

Article • 11/17/2023

In this topic you'll create a very simple "Hello, World!" project for Win2D.

In Visual Studio, create a new project from one of the following project templates:

- **WinUI 3 (Windows App SDK)**. To create a new WinUI 3 project, use the **Blank App, Packaged (WinUI 3 in Desktop)** project template. You can find that project template by choosing language: either *C#* or *C++*; platform: *Windows*; project type: *Desktop*.
- **Universal Windows Platform (UWP)**. To create a new UWP project, use the **Blank App (Universal Windows)** or **Blank App (C++/WinRT)** or **Blank App (Universal Windows - C++/CX)** project template. For language, choose: either *C#* or *C++*; platform: *Windows*; project type: *UWP*.

> **ⓘ Important**
>
> For info about how to set up your project to use Win2D, see **Reference the Win2D NuGet package**.

To host Win2D content, you'll need to add a Win2D **CanvasControl** to your project's `MainWindow.xaml` (or `MainPage.xaml`, for a UWP project).

First, add the following xml namespace declaration:

XAML

```
xmlns:win2dcanvas="using:Microsoft.Graphics.Canvas.UI.Xaml"
```

And then add a **CanvasControl**, prefixed with that xml namespace. For example, you could add a **Grid** as your layout root, like this:

XAML

```
<Grid>
    <win2dcanvas:CanvasControl Draw="CanvasControl_Draw"
ClearColor="CornflowerBlue"/>
</Grid>
```

The project won't build at the moment, due to the referenced-but-not-implemented **Draw** event handler. So we'll remedy that next, while we add some drawing code to

interact with the **CanvasControl**.

For a WinUI 3 (Windows App SDK) project

For a C# project, add the following event handler to `MainWindow.xaml.cs`:

C#

```
// MainWindow.xaml.cs
...
public sealed partial class MainWindow : Window
{
    ...
    void CanvasControl_Draw(
        Microsoft.Graphics.Canvas.UI.Xaml.CanvasControl sender,
        Microsoft.Graphics.Canvas.UI.Xaml.CanvasDrawEventArgs args)
    {
        args.DrawingSession.DrawEllipse(155, 115, 80, 30,
Microsoft.UI.Colors.Black, 3);
        args.DrawingSession.DrawText("Hello, Win2D World!", 100, 100,
Microsoft.UI.Colors.Yellow);
    }
}
...
```

For a C++/WinRT project, add the following event handler to `MainWindow.xaml.h` and `MainWindow.xaml.cpp`:

C++/WinRT

```
// MainWindow.xaml.h
...
void CanvasControl_Draw(
    winrt::Microsoft::Graphics::Canvas::UI::Xaml::CanvasControl const&
sender,
    winrt::Microsoft::Graphics::Canvas::UI::Xaml::CanvasDrawEventArgs const&
args);
...

// MainWindow.xaml.cpp
...
namespace winrt::MYPROJECT::implementation
{
    ...
    void MainWindow::CanvasControl_Draw(
        winrt::Microsoft::Graphics::Canvas::UI::Xaml::CanvasControl const&
sender,
        winrt::Microsoft::Graphics::Canvas::UI::Xaml::CanvasDrawEventArgs
const& args)
    {
```

```
        args.DrawingSession().DrawEllipse(155, 115, 80, 30,
winrt::Microsoft::UI::Colors::Black(), 3);
        args.DrawingSession().DrawText(L"Hello, Win2D World!", 100, 100,
winrt::Microsoft::UI::Colors::Yellow());
    }
}
```

You can now build and run the project. You'll see some Win2D content—a black ellipse with a yellow "Hello, World!" message in front of it.

For a UWP project

For a C# project, you can use the same C# code as for a WinUI 3 project (see the For a WinUI 3 project section above). The only differences are that you'll be editing `MainPage.xaml.cs` instead of `MainWindow.xaml.cs`. And you'll need to change `Microsoft.UI.Colors` to `Windows.UI.Colors`.

For a C++/WinRT project, add the following code to `pch.h`, `MainPage.h`, and `MainPage.cpp`:

C++/WinRT

```
// pch.h
...
#include <winrt/Microsoft.Graphics.Canvas.UI.Xaml.h>

// MainPage.h
...
void CanvasControl_Draw(
    winrt::Microsoft::Graphics::Canvas::UI::Xaml::CanvasControl const&
sender,
    winrt::Microsoft::Graphics::Canvas::UI::Xaml::CanvasDrawEventArgs const&
args);
...

// MainPage.cpp
...
namespace winrt::MYPROJECT::implementation
{
    ...
    void MainPage::CanvasControl_Draw(
        winrt::Microsoft::Graphics::Canvas::UI::Xaml::CanvasControl const&
sender,
        winrt::Microsoft::Graphics::Canvas::UI::Xaml::CanvasDrawEventArgs
const& args)
    {
        args.DrawingSession().DrawEllipse(155, 115, 80, 30,
winrt::Windows::UI::Colors::Black(), 3);
        args.DrawingSession().DrawText(L"Hello, Win2D World!", 100, 100,
```

```
winrt::Windows::UI::Colors::Yellow());
    }
}
```

For a C++/CX project, add the following event handler to `MainPage.xaml.h` and `MainPage.xaml.cpp`:

C++/CX

```
// MainPage.xaml.h
...
void CanvasControl_Draw(
    Microsoft::Graphics::Canvas::UI::Xaml::CanvasControl^ sender,
    Microsoft::Graphics::Canvas::UI::Xaml::CanvasDrawEventArgs^ args);
...

// MainWindow.xaml.cpp
...
void MainPage::CanvasControl_Draw(
    Microsoft::Graphics::Canvas::UI::Xaml::CanvasControl^ sender,
    Microsoft::Graphics::Canvas::UI::Xaml::CanvasDrawEventArgs^ args)
{
    args->DrawingSession->DrawEllipse(155, 115, 80, 30,
Windows::UI::Colors::Black, 3);
    args->DrawingSession->DrawText("Hello, Win2D World!", 100, 100,
Windows::UI::Colors::Yellow);
}
```

Build a simple Win2D app

Article • 10/25/2023

This tutorial introduces some of the basic drawing capabilities of Win2D. You'll learn how to:

- Add Win2D to a C# XAML Windows project.
- Draw text and geometry.
- Apply filter effects.
- Animate your Win2D content.
- Follow Win2D best practices.

Set up your dev machine

Make sure to set up your machine with all the necessary tools:

- Install Visual Studio
  - Include the UWP or Windows SDK (depending on your needs), 17763+
- If using UWP, ensure to also enable developer mode

Create a new Win2D project

Follow the steps in the Win2D "Hello, World!" quickstart to create a new project using Win2D, and to add a reference to the Win2D NuGet package. You can use either WinUI 3 (Windows App SDK) or the Universal Windows Platform (UWP).

Add a Win2D CanvasControl to your app's XAML

1. In order to use Win2D, you need somewhere to draw your graphics. In a XAML app, the simplest way to do this is to add a CanvasControl to your XAML page.

Before you continue, first ensure that the project's Architecture option is set to `x86` or `x64` and **not** to `Any CPU`. Win2D is implemented in C++, and therefore projects that use Win2D need to be targeted to a specific CPU architecture.

1. Navigate to `MainPage.xaml` in your project by double clicking on it in Solution Explorer. This will open the file. For convenience, you can double click on the XAML

button in the Designer tab; this will hide the visual designer and reserve all of the space for the code view.

2. Before you add the control, you first have to tell XAML where **CanvasControl** is defined. To do this, go to the definition of the **Page** element, and add this directive: `xmlns:canvas="using:Microsoft.Graphics.Canvas.UI.Xaml"`. Your XAML should now look like this:

XAML

```
<Page
    ...
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    xmlns:canvas="using:Microsoft.Graphics.Canvas.UI.Xaml"
    mc:Ignorable="d">
```

4. Now, add a new `canvas:CanvasControl` as a child element to the root **Grid** element. Give the control a name—for example, "canvas". Your XAML should now look like this:

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <canvas:CanvasControl x:Name="canvas"/>
</Grid>
```

5. Next, define an event handler for the Draw event. **CanvasControl** raises `Draw` whenever your app needs to draw or redraw its content. The easiest way is to let Visual Studio AutoComplete assist you. In the **CanvasControl** definition, begin typing a new attribute for the `Draw` event handler:

XAML

```
<canvas:CanvasControl x:Name="canvas" Draw="canvas_Draw" />
```

Note

Once you have entered in `Draw="`, Visual Studio should pop up a box prompting you to let it automatically fill out the right definition for the event handler. Press TAB to accept Visual Studio's default event handler. This will also automatically add a correctly formatted event handler method in your code behind

(`MainPage.xaml.cs``). Don't worry if you didn't use AutoComplete; you can manually add the event handler method in the next step.

Draw your first text in Win2D

1. Now, let's go to the C# code behind. Open `MainPage.xaml.cs` from Solution Explorer.

2. At the top of the C# file are various namespace definitions. Add the following namespaces:

C#

```
using Windows.UI;
using System.Numerics;
using Microsoft.Graphics.Canvas;
using Microsoft.Graphics.Canvas.Effects;
```

3. Next, you should see the following blank event handler which was inserted by AutoComplete:

C#

```
private void canvas_Draw(
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasControl sender,
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasDrawEventArgs args)
{
}
```

(If you didn't use AutoComplete in the previous step, add this code now.)

4. The CanvasDrawEventArgs parameter exposes a member, **DrawingSession**, which is of the type CanvasDrawingSession. This class provides most of the basic drawing functionality in Win2D: it has methods such as CanvasDrawingSession.DrawRectangle, CanvasDrawingSession.DrawImage, and the method you need to draw text, CanvasDrawingSession.DrawText.

Add the following code to the `canvas_Draw` method:

C#

```
args.DrawingSession.DrawText("Hello, World!", 100, 100, Colors.Black);
```

The first argument, `"Hello, World!"`, is the string that you want Win2D to display. The two "100"s tell Win2D to offset this text by 100 DIPs (device-independent pixels) to the right and down. Finally, `Colors.Black` defines the color of the text.

5. Now you are ready to run your first Win2D app. Press the F5 key to compile and launch. You should see an empty window with "Hello, world!" in black.

Correctly dispose of Win2D resources

1. Before continuing on to draw other kinds of content, you first should add some code to ensure your app avoids memory leaks. Most Win2D applications written in a .NET language and using a Win2D control like CanvasControl need to follow the below steps. Strictly speaking, your simple "Hello, world" app is not affected, but this is a good practice to follow in general.

For more information, see Avoiding memory leaks.

2. Open `MainPage.xaml` and find the Page XAML element that contains your **CanvasControl**. It should be the first element in the file.

3. Add a handler for the `Unloaded` event. Your XAML should look like this:

XAML

```
<Page
    ...
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    xmlns:canvas="using:Microsoft.Graphics.Canvas.UI.Xaml"
    mc:Ignorable="d"
    Unloaded="Page_Unloaded">
```

4. Go to `MainPage.xaml.cs` and find the `Page_Unloaded` event handler. Add the following code:

C#

```
void Page_Unloaded(object sender, RoutedEventArgs e)
{
    this.canvas.RemoveFromVisualTree();
    this.canvas = null;
}
```

5. If your app contains multiple Win2D controls, then you need to repeat the above steps for each XAML page that contains a Win2D control. Your app currently only

has a single **CanvasControl** so you're all done.

Draw some shapes

1. It's just as easy to add 2D geometry to your app. Add the following code to the end of `canvas_Draw`:

```
C#

args.DrawingSession.DrawCircle(125, 125, 100, Colors.Green);
args.DrawingSession.DrawLine(0, 0, 50, 200, Colors.Red);
```

The arguments to these two methods are similar to `DrawText`. A circle is defined by a center point (125, 125), a radius (100), and a color (Green). A line is defined by a beginning (0, 0), an end (50, 200) and a color (Red).

12. Now, press F5 to run the app. You should see "Hello, world!" along with a green circle and red line.

You may be wondering how to control more advanced drawing options, such as line thickness and dashes, or more complex fill options such as using brushes. Win2D provides all of these options and more, and makes it easy to use them when you want. All of the `Draw(...)` methods offer many overloads that can accept additional parameters such as CanvasTextFormat (font family, size, etc) and CanvasStrokeStyle (dashes, dots, endcaps, etc). Feel free to explore the API surface to learn more about these options.

Dynamically generate drawing parameters

1. Now, let's add some variety by drawing a bunch of shapes and text with randomized colors.

Add the following code to the top of your `MainPage` class. This is helper functionality to generate random values that you will use when drawing:

```
C#

Random rnd = new Random();
private Vector2 RndPosition()
{
    double x = rnd.NextDouble() * 500f;
    double y = rnd.NextDouble() * 500f;
    return new Vector2((float)x, (float)y);
}
```

```
private float RndRadius()
{
    return (float)rnd.NextDouble() * 150f;
}

private byte RndByte()
{
    return (byte)rnd.Next(256);
}
```

2. Modify your `canvas_Draw` method to draw using these random parameters:

C#

```
private void canvas_Draw(
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasControl sender,
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasDrawEventArgs args)
{
    args.DrawingSession.DrawText("Hello, World!", RndPosition(),
Color.FromArgb(255, RndByte(), RndByte(), RndByte()));
    args.DrawingSession.DrawCircle(RndPosition(), RndRadius(),
Color.FromArgb(255, RndByte(), RndByte(), RndByte()));
    args.DrawingSession.DrawLine(RndPosition(), RndPosition(),
Color.FromArgb(255, RndByte(), RndByte(), RndByte()));
}
```

Let's break down how `DrawText` has changed. `"Hello, World!"` remains the same as before. The x and y offset parameters have been replaced with a single System.Numerics.Vector2 which is generated by `RndPosition`. Finally, instead of using a predefined color, `Color.FromArgb` allows you to define a color using A, R, G and B values. A is alpha, or the opacity level; in this case you always want fully opaque (255).

`DrawCircle` and `DrawLine` operate similarly to `DrawText`.

3. Finally, wrap your drawing code in a `for` loop. You should end up with the following `canvas_Draw` code:

C#

```
for (int i = 0; i < 100; i++)
{
    args.DrawingSession.DrawText("Hello, World!", RndPosition(),
Color.FromArgb(255, RndByte(), RndByte(), RndByte()));
    args.DrawingSession.DrawCircle(RndPosition(), RndRadius(),
Color.FromArgb(255, RndByte(), RndByte(), RndByte()));
    args.DrawingSession.DrawLine(RndPosition(), RndPosition(),
```

```
Color.FromArgb(255, RndByte(), RndByte(), RndByte()));
}
```

4. Run the app again. You should see a whole bunch of text, lines and circles with random positions and sizes.

Apply an image effect to your content

Image effects, also known as filter effects, are graphical transformations that are applied to pixel data. Saturation, hue rotation, and Gaussian blur are some common image effects. Image effects can be chained together, producing sophisticated visual appearance for minimal effort.

You use image effects by providing a source image (the content you're starting with), creating an effect such as GaussianBlurEffect, setting properties such as BlurAmount, and then drawing the effect's output with `DrawImage`.

To apply an image effect to your text and shapes, you need to first render that content into a CanvasCommandList. This object is usable as an input to your effect.

2. Change your `canvas_Draw` method to use the following code:

C#

```
CanvasCommandList cl = new CanvasCommandList(sender);

using (CanvasDrawingSession clds = cl.CreateDrawingSession())
{
    for (int i = 0; i < 100; i++)
    {
        clds.DrawText("Hello, World!", RndPosition(), Color.FromArgb(255,
RndByte(), RndByte(), RndByte()));
        clds.DrawCircle(RndPosition(), RndRadius(), Color.FromArgb(255,
RndByte(), RndByte(), RndByte()));
        clds.DrawLine(RndPosition(), RndPosition(), Color.FromArgb(255,
RndByte(), RndByte(), RndByte()));
    }
}
```

Just like how you obtain a `CanvasDrawingSession` from `CanvasDrawEventArgs` which you can draw with, you can create a `CanvasDrawingSession` from a `CanvasCommandList`. The only difference is that when you draw to the command list's drawing session (clds), you are not directly rendering to the **CanvasControl**. Instead, the command list is an intermediate object that stores the results of rendering for later use.

You may have noticed the `using` block that wraps the command list's drawing session. Drawing sessions implement IDisposable and must be disposed when you are done rendering (the `using` block does this). The `CanvasDrawingSession` that you obtain from `CanvasDrawEventArgs` automatically is closed for you, but you must dispose any drawing sessions that you explicitly created.

3. Finally, define the `GaussianBlurEffect` by adding the following code to the end of the `canvas_Draw` method:

C#

```
GaussianBlurEffect blur = new GaussianBlurEffect();
blur.Source = cl;
blur.BlurAmount = 10.0f;
args.DrawingSession.DrawImage(blur);
```

4. Run the app again. You should see your lines, text and circles with a blurry appearance.

Animate your app with CanvasAnimatedControl

. Win2D gives you the ability to update and animate your content in realtime, for example by changing the blur radius of the Gaussian blur with every frame. To do this, you will use CanvasAnimatedControl.

CanvasControl is best suited for mostly static graphics content - it only raises the `Draw` event when your content needs to be updated or redrawn. If you have continually changing content then you should consider using `CanvasAnimatedControl` instead. The two controls operate very similarly, except `CanvasAnimatedControl` raises the `Draw` event on a periodic basis; by default it is called 60 times per second.

2. To switch to `CanvasAnimatedControl`, go to `MainPage.xaml`, delete the **CanvasControl** line, and replace it with the following XAML:

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <canvas:CanvasAnimatedControl x:Name="canvas" Draw="canvas_DrawAnimated"
CreateResources="canvas_CreateResources"/>
</Grid>
```

Just like with **CanvasControl**, let AutoComplete create the `Draw` event handler for you. By default, Visual Studio will name this handler `canvas_Draw_1` because `canvas_Draw`

already exists; here, we've renamed the method `canvas_AnimatedDraw` to make it clear that this is a different event.

In addition, you are also handling a new event, CreateResources. Once again, let AutoComplete create the handler.

Now that your app will be redrawing at 60 frames per second, it is more efficient to create your Win2D visual resources once and reuse them with every frame. It is inefficient to create a `CanvasCommandList` and draw 300 elements into it 60 times per second when the content remains static. `CreateResources` is an event that is fired only when Win2D determines you need to recreate your visual resources, such as when the page is loaded.

3. Switch back to `MainPage.xaml.cs`. Find your `canvas_Draw` method which should look like this:

C#

```
private void canvas_Draw(
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasControl sender,
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasDrawEventArgs args)
{
    CanvasCommandList cl = new CanvasCommandList(sender);
    using (CanvasDrawingSession clds = cl.CreateDrawingSession())
    {
        for (int i = 0; i < 100; i++)
        {
            clds.DrawText("Hello, World!", RndPosition(),
Color.FromArgb(255, RndByte(), RndByte(), RndByte()));
            clds.DrawCircle(RndPosition(), RndRadius(), Color.FromArgb(255,
RndByte(), RndByte(), RndByte()));
            clds.DrawLine(RndPosition(), RndPosition(), Color.FromArgb(255,
RndByte(), RndByte(), RndByte()));
        }
    }

    GaussianBlurEffect blur = new GaussianBlurEffect();
    blur.Source = cl;
    blur.BlurAmount = 10.0f;
    args.DrawingSession.DrawImage(blur);
}
```

The vast majority of this existing draw code does not need to be executed with every frame: the command list containing the text, lines and circles remains the same with every frame, and the only thing that changes is the blur radius. Therefore, you can move this "static" code into `CreateResources`.

To do this, first cut (CTRL+X) the entire contents of `canvas_Draw`, except for the very last line (`args.DrawingSession.DrawImage(blur);`). You can now delete the remainder of `canvas_Draw` as it is no longer needed: recall that `CanvasAnimatedControl` has its own distinct `Draw` event.

4. Find the automatically generated `canvas_CreateResources` method:

```
C#

private void canvas_CreateResources(
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasAnimatedControl sender,
    Microsoft.Graphics.Canvas.UI.CanvasCreateResourcesEventArgs args)
{}
```

Paste (CTRL+V) your previously cut code into this method. Next, move the declaration of `GaussianBlurEffect` outside the method body so the variable becomes a member of the MainPage class. Your code should now look like the following:

```
C#

GaussianBlurEffect blur;
private void canvas_CreateResources(
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasAnimatedControl sender,
    Microsoft.Graphics.Canvas.UI.CanvasCreateResourcesEventArgs args)
{
    CanvasCommandList cl = new CanvasCommandList(sender);
    using (CanvasDrawingSession clds = cl.CreateDrawingSession())
    {
        for (int i = 0; i < 100; i++)
        {
            clds.DrawText("Hello, World!", RndPosition(),
Color.FromArgb(255, RndByte(), RndByte(), RndByte()));
            clds.DrawCircle(RndPosition(), RndRadius(), Color.FromArgb(255,
RndByte(), RndByte(), RndByte()));
            clds.DrawLine(RndPosition(), RndPosition(), Color.FromArgb(255,
RndByte(), RndByte(), RndByte()));
        }
    }

    blur = new GaussianBlurEffect()
    {
        Source = cl,
        BlurAmount = 10.0f
    };
}
```

5. Now you can animate the Gaussian blur. Find the `canvas_DrawAnimated` method and add the following code:

C#

```
private void canvas_DrawAnimated(
    Microsoft.Graphics.Canvas.UI.Xaml.ICanvasAnimatedControl sender,
    Microsoft.Graphics.Canvas.UI.Xaml.CanvasAnimatedDrawEventArgs args)
{
    float radius = (float)(1 + Math.Sin(args.Timing.TotalTime.TotalSeconds))
* 10f;
    blur.BlurAmount = radius;
    args.DrawingSession.DrawImage(blur);
}
```

This reads the total elapsed time provided by CanvasAnimatedDrawEventArgs and uses this to calculate the desired blur amount; the sine function provides an interesting variation over time. Finally, the `GaussianBlurEffect` is rendered.

6. Run the app to see the blurred content change over time.

Congratulations on completing this quick start tutorial! Hopefully you've seen how you can use Win2D to create a rich, animated visual scene with just a few lines of C# and XAML code.

Win2D in a Core App project

Article • 11/20/2023

The Win2D quickstart and Build a simple Win2D app topics both show Win2D being used in projects that use the XAML user-interface (UI) framework. But you can *also* use Win2D in a project that doesn't use XAML at all.

This topic shows you how, in a UWP Core App project, you can use a CanvasSwapChain to display Win2D content. And you can run the resulting app on both Windows and Xbox. This type of app is also referred to as a *CoreApplication app*, or a *UWP DirectX app*.

> **Platform APIs:** IFrameworkViewSource, IFrameworkView, CoreWindow, CoreApplication, CoreApplicationView, CanvasSwapChain, CanvasDrawingSession

Create and configure a new project

We'll be creating a XAML project just to get started. But we'll be removing all of the XAML from it as we proceed.

1. In Visual Studio, create a new project from the **Blank App (Universal Windows)** project template. For language, choose: *C#*; platform: *Windows*; project type: *UWP*.
2. Then, to set up the project to use Win2D, see Reference the Win2D NuGet package.

Modify the project files

1. Since we won't be using XAML, go ahead and delete the following files from the project: `App.xaml`, `App.xaml.cs`, `MainPage.xaml`, and `MainPage.xaml.cs`.
2. And then add to the project a new *Class*; name the file `Program.cs`.

Add code to Program.cs

1. Replace the entire contents of `Program.cs` with the following code listing:

```
C#

// Program.cs
using Microsoft.Graphics.Canvas;
```

```
using Windows.ApplicationModel.Core;
using Windows.Graphics.Display;
using Windows.UI;
using Windows.UI.Core;

public sealed class App : IFrameworkViewSource, IFrameworkView
{
    private CoreApplicationView view;
    private CoreWindow window;
    private CanvasSwapChain swapChain;

    public IFrameworkView CreateView()
    {
        return this;
    }

    public void Initialize(CoreApplicationView applicationView)
    {
        this.view = applicationView;
    }

    public void SetWindow(CoreWindow window)
    {
        this.view.TitleBar.ExtendViewIntoTitleBar = true;
        this.window = window;
    }

    public void Load(string entryPoint)
    {
    }

    public void Run()
    {
        this.swapChain = CanvasSwapChain.CreateForCoreWindow(
            resourceCreator: CanvasDevice.GetSharedDevice(),
            coreWindow: this.window,
            dpi: DisplayInformation.GetForCurrentView().LogicalDpi);

        this.swapChain.ResizeBuffers((float)this.window.Bounds.Width,
(float)this.window.Bounds.Height);

        using (CanvasDrawingSession session =
this.swapChain.CreateDrawingSession(Colors.Black))
        {
            session.DrawEllipse(155, 115, 80, 30, Colors.Cyan, 3);
            session.DrawText("Hello, Win2D World!", 100, 100,
Colors.Yellow);
        }

        this.swapChain.Present();

        this.window.Activate();

this.window.Dispatcher.ProcessEvents(CoreProcessEventsOption.ProcessUntilQui
t);
```

```
    }

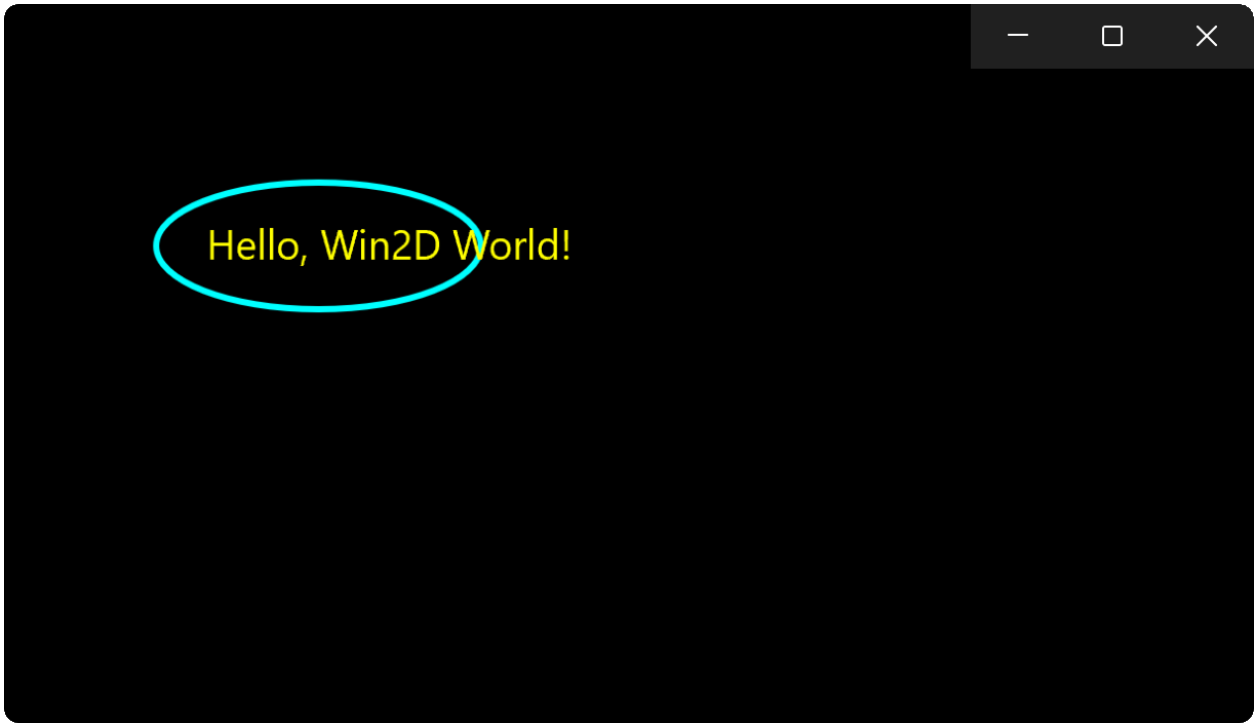
    public void Uninitialize()
    {
    }
}

public static class Program
{
    public static void Main()
    {
        CoreApplication.Run(new App());
    }
}
```

> **Note**
>
> This example includes a separate **Program** class containing the **Main** entry point for the program, which then starts the actual **CoreApplication** app. But it's not necessary to place the entry point in a separate class; you could instead just move the **Main** method inside of the **App** class if you prefer structuring code that way. If you're using C# 10 or above, then the `CoreApplication.Run(new App());` expression statement could also be in a top-level statement.

Finishing up

Now you can go ahead and build and run the app, and see the following output:



In terms of the app model, the code in the previous section has an **App** class that implements the IFrameworkViewSource and IFrameworkView interfaces, which are necessary for a Core App. And the **Main** function entry point calls **CoreApplication.Run** to run an instance of that **App** class.

In terms of the graphics, the code creates a CanvasSwapChain for the main CoreWindow, and draws content into it.

You can extend the sample app above in any way that you like. For example, this could be a good starting point for a simple 2D game.

Features

Article • 05/29/2023

Win2D includes an extensive set of features to support lots of different scenarios. Here's a list of most of them, with useful links to related docs and API references to learn more.

Bitmap graphics

- Load, save and draw bitmap images
- Render to texture
- Use bitmaps as opacity masks
- Sprite batch API for efficiently drawing large numbers of bitmaps
- Use block compressed bitmap formats to save memory
- Load, save, and draw virtual bitmaps, which can be larger than the maximum GPU texture size and are automatically split into tiles

Vector graphics

- Draw primitive shapes (lines, rectangles, circles, etc.) or arbitrarily complex geometry
- Fill shapes using solid colors, image brushes, or linear and radial gradients
- Draw lines of any width with flexible stroke styles (dotted, dashed, etc.)
- High quality antialiasing
- Rich geometry manipulation (union, intersect, compute point on path, tessellate, etc.)
- Clip drawing to arbitrary geometric regions
- Capture drawing operations in command lists for later replay
- Rasterize ink strokes (from a stylus)
- Load, draw, and manipulate SVG vector graphics

Powerful image processing effects

- Blurs
- Blends
- Color adjustments (brightness, contrast, exposure, highlights & shadows, etc.)
- Filters (convolve, edge detection, emboss, sharpen)
- Lighting

- Custom pixel shaders
- Fully custom effects
- And many more ...

Text

- Fully internationalized Unicode text rendering
- Text layouts can be drawn, measured, or hit-tested against
- Convert text outlines to geometry
- Enumerate fonts and query their metrics
- Draw or manipulate individual glyph runs to create custom text layouts

Interop with Direct2D

Article • 05/29/2023

Win2D is implemented as a layer on top of Direct2D, and supports interop in both directions. If you have a Win2D object, you can access the native Direct2D object that is used to implement it. If you have a Direct2D object, you can look up the Win2D object that wraps it, or create a new wrapper if one did not already exist.

Interop allows you to mix and match Win2D with native DirectX APIs. You can write an app that mostly uses Win2D, but drop down to native DirectX at any point - perhaps to call into some other API or 3rd party component that requires native interfaces. Or your app can be mostly native DirectX, yet you can switch over to Win2D in specific places where you want its extra convenience or C# support.

Interop APIs

C++/CX interop APIs are defined in the header Microsoft.Graphics.Canvas.native.h:

C++

```
#include <Microsoft.Graphics.Canvas.native.h>

using namespace Microsoft::Graphics::Canvas;
```

To get the native Direct2D object that is wrapped by a Win2D object:

C++

```
template<typename T, typename U>
Microsoft::WRL::ComPtr<T> GetWrappedResource(U^ wrapper);

template<typename T, typename U>
Microsoft::WRL::ComPtr<T> GetWrappedResource(CanvasDevice^ device, U^ wrapper);

template<typename T, typename U>
Microsoft::WRL::ComPtr<T> GetWrappedResource(CanvasDevice^ device, U^ wrapper,
float dpi);
```

For most types `GetWrappedResource` can be called with only a Win2D wrapper object as parameter. For a few types (see below table) it must also be passed a device and/or DPI value. It is not an error to pass a device or DPI when using `GetWrappedResource` with types that do not require them.

To get a Win2D object wrapping a native Direct2D object:

C++

```
template<typename WRAPPER>
WRAPPER^ GetOrCreate(IUnknown* resource);

template<typename WRAPPER>
WRAPPER^ GetOrCreate(CanvasDevice^ device, IUnknown* resource);

template<typename WRAPPER>
WRAPPER^ GetOrCreate(ID2D1Device1* device, IUnknown* resource);

template<typename WRAPPER>
WRAPPER^ GetOrCreate(CanvasDevice^ device, IUnknown* resource, float dpi);

template<typename WRAPPER>
WRAPPER^ GetOrCreate(ID2D1Device1* device, IUnknown* resource, float dpi);
```

`GetOrCreate` returns an existing wrapper instance if one already exists, or creates a new wrapper if one does not. Calling it repeatedly on the same native object will return the same wrapper each time, as long as that wrapper instance continues to exist. If all references to the wrapper are released such that its reference count goes to zero and it is destroyed, any later call to `GetOrCreate` will have to create a new wrapper.

For some types `GetOrCreate` can be called with only a Direct2D resource object as parameter, while for other types (see below table) it must also be passed a device and DPI value. It is not an error to pass a device or DPI when using `GetOrCreate` with types that do not require them. If a Win2D wrapper already exists, it is ok to omit the device and DPI even for types that would normally need them: these parameters are only used when creating new wrapper instances.

`GetOrCreate` understands inheritance hierarchies and will always create the appropriate most-derived wrapper type. For instance if you call `GetOrCreate<CanvasBitmap>(ID2D1Bitmap1*)` with an `ID2D1Bitmap1` that has the `D2D1_BITMAP_OPTIONS_TARGET` flag, the returned wrapper instance will in fact be a `CanvasRenderTarget` (which derives from `CanvasBitmap`). The other way around, if you call `GetOrCreate<CanvasRenderTarget>(ID2D1Bitmap1*)` with an `ID2D1Bitmap1` that does not have `D2D1_BITMAP_OPTIONS_TARGET`, this will throw an invalid cast exception.

Taking this to the extreme, it is valid to call `GetOrCreate<Object>(IUnknown*)`, and also `GetWrappedResource<IUnknown>(Object^)`.

Types that support interop

Win2D type	Direct2D type	`GetOrCreate` parameters	`GetWrappedResource` parameters

Win2D type	Direct2D type	`GetOrCreate` parameters	`GetWrappedResource` parameters
CanvasBitmap	`ID2D1Bitmap1` without `D2D1_BITMAP_OPTIONS_TARGET`	Device	-
CanvasCachedGeometry	`ID2D1GeometryRealization`	Device	-
CanvasCommandList	`ID2D1CommandList`	Device	-
CanvasDevice	`ID2D1Device1`	-	-
CanvasDrawingSession	`ID2D1DeviceContext1`	-	-
CanvasFontFace	`IDWriteFontFaceReference`	-	-
CanvasFontSet	`IDWriteFontSet`	-	-
CanvasGeometry	`ID2D1Geometry`, or one of its derived interfaces `ID2D1PathGeometry`, `ID2D1RectangleGeometry`, `ID2D1RoundedRectangleGeometry`, `ID2D1EllipseGeometry`, `ID2D1TransformedGeometry`, or `ID2D1GeometryGroup`	Device	-
CanvasGradientMesh	`ID2D1GradientMesh`	Device	-
CanvasImageBrush	`ID2D1BitmapBrush1` (if the image is a `CanvasBitmap` and `SourceRectangle` is `null`) or `ID2D1ImageBrush` (if it is any other type of `ICanvasImage`, or if `SourceRectangle is set`)	Device	Optional DPI^1
CanvasLinearGradientBrush	`ID2D1LinearGradientBrush`	Device	-
CanvasNumberSubstitution	`IDWriteNumberSubstitution`	-	-
CanvasRadialGradientBrush	`ID2D1RadialGradientBrush`	Device	-
CanvasRenderTarget	`ID2D1Bitmap1` with `D2D1_BITMAP_OPTIONS_TARGET`	Device	-
CanvasSolidColorBrush	`ID2D1SolidColorBrush`	Device	-
CanvasStrokeStyle	`ID2D1StrokeStyle1`	-	Device
CanvasSvgDocument	`ID2D1SvgDocument`^2	Device	-
CanvasSwapChain	`IDXGISwapChain1`	Device, DPI	-

Win2D type	Direct2D type	`GetOrCreate` parameters	`GetWrappedResource` parameters
CanvasTestFormat	`IDWriteTextFormat1`	-	-
CanvasTextLayout	`IDWriteTextLayout3`	Device	-
CanvasTextRenderingParameters	`IDWriteRenderingParams3`	-	-
CanvasTypography	`IDWriteTypography`	-	-
CanvasVirtualBitmap	`ID2D1ImageSource` or `ID2D1TransformedImageSource`	Device	-
ColorManagementProfile	`ID2D1ColorContext`	Device	Device
EffectTransferTable3D	`ID2D1LookupTable3D`	Device	-
Microsoft.Graphics.Canvas.Effects.* (multiple Win2D classes map to the same D2D type)	`ID2D1Effect` with the appropriate `D2D1_PROPERTY_TYPE_CLSID`	Device	Device, optional DPI^1

> **Note**
>
> ^1: optional DPI means it is valid to call `GetWrappedResource` for this type without specifying a DPI value, but if you do specify DPI, Win2D may be able to more efficiently configure effect graphs by leaving out redundant DPI compensation nodes. This applies when calling `GetWrappedResource` on an effect, or on a `CanvasImageBrush` that has an effect as its source image.

> **Note**
>
> ^2: when a `CanvasSvgDocument` is produced from an `ID2D1SvgDocument` using native C++ interop, the `ID2D1SvgDocument`'s viewport size is ignored.

Interop using C++/CX

Here's an example of how Win2D can interoperate with Direct2D, using C++:

C++

```
#include <Microsoft.Graphics.Canvas.native.h>
#include <d2d1_2.h>

using namespace Microsoft::Graphics::Canvas;
```

```
using namespace Microsoft::WRL;

// Interop Win2D -> Direct2D.
CanvasDevice^ canvasDevice = ...;
CanvasBitmap^ canvasBitmap = ...;

ComPtr<ID2D1Device> nativeDevice = GetWrappedResource<ID2D1Device>
(canvasDevice);
ComPtr<ID2D1Bitmap1> nativeBitmap = GetWrappedResource<ID2D1Bitmap1>
(canvasBitmap);

// Interop Direct2D -> Win2D.
canvasDevice = GetOrCreate<CanvasDevice>(nativeDevice.Get());
bitmap = GetOrCreate<CanvasBitmap>(canvasDevice, nativeBitmap.Get());
```

> **Note**
>
> Interop is also possible via C#, through various means (eg. using built-in COM/WinRT interop, via **CsWinRT** 's APIs, or using blittable bindings). For more info on manual interop in C#, refer to the docs about CsWinRT.

Interop using C++/WinRT

You can also perform interop using C++/WinRT with some modification of the above. Note that the C++/WinRT headers for the Win2D Windows Runtime Components should be generated automatically when you add the Win2D NuGet package to your C++/WinRT project. However, for interop you will still need to use the header file Microsoft.Graphics.Canvas.native.h which contains the low-level ABI interface `ICanvasFactoryNative` in the namespace `ABI::Microsoft::Graphics::Canvas`. The interface has the following functions which you can use to perform interop.

C++

```
HRESULT GetOrCreate(ICanvasDevice* device, IUnknown* resource, float dpi,
IInspectable** wrapper);
HRESULT GetNativeResource(ICanvasDevice* device, float dpi, REFIID iid, void**
resource);
```

Here is an example showing how to create a `CanvasVirtualBitmap` from an `IWICBitmapSource` starting with the `IWICBitmapSource` and the shared `CanvasDevice`.

C++

```
#include "pch.h"
#include <wincodec.h>
#include <wincodecsdk.h>
```

```
#include <winrt/Microsoft.Graphics.Canvas.h> //This defines the C++/WinRT
interfaces for the Win2D Windows Runtime Components
#include <Microsoft.Graphics.Canvas.h> //This defines the low-level ABI
interfaces for the Win2D Windows Runtime Components
#include <Microsoft.Graphics.Canvas.native.h> //This is for interop
#include <d2d1_3.h>

using namespace winrt::Microsoft::Graphics::Canvas;
namespace abi {
  using namespace ABI::Microsoft::Graphics::Canvas;
}

namespace winrt::Win2DInteropTest::implementation {
  CanvasVirtualBitmap
CreateVirtualBitmapFromBitmapSource(com_ptr<IWICBitmapSource> const&
pBitmapSource){
    CanvasDevice sharedDevice = CanvasDevice::GetSharedDevice();

    //First we need to get an ID2D1Device1 pointer from the shared CanvasDevice
    com_ptr<abi::ICanvasResourceWrapperNative> nativeDeviceWrapper =
sharedDevice.as<abi::ICanvasResourceWrapperNative>();
    com_ptr<ID2D1Device1> pDevice{ nullptr };
    check_hresult(nativeDeviceWrapper->GetNativeResource(nullptr, 0.0f,
guid_of<ID2D1Device1>(), pDevice.put_void()));

    //Next we need to call some Direct2D functions to create the
ID2D1ImageSourceFromWic object
    com_ptr<ID2D1DeviceContext1> pContext{ nullptr };
    check_hresult(pDevice-
>CreateDeviceContext(D2D1_DEVICE_CONTEXT_OPTIONS_NONE, pContext.put()));
    com_ptr<ID2D1DeviceContext2> pContext2 = pContext.as<ID2D1DeviceContext2>
();
    com_ptr<ID2D1ImageSourceFromWic> pImage{ nullptr };
    check_hresult(pContext2->CreateImageSourceFromWic(pBitmapSource.get(),
D2D1_IMAGE_SOURCE_LOADING_OPTIONS_RELEASE_SOURCE, pImage.put()));

    //Finally we need to wrap the ID2D1ImageSourceFromWic object inside
    com_ptr<::IInspectable> pInspectable{ nullptr };
    auto factory = winrt::get_activation_factory<CanvasDevice,
abi::ICanvasFactoryNative>(); //abi::ICanvasFactoryNative is the activation
factory for the CanvasDevice class
    check_hresult(factory->GetOrCreate(sharedDevice.as<abi::ICanvasDevice>
().get(), pImage.as<::IUnknown>().get(), 0.0f, pInspectable.put())); //Note
abi::ICanvasDevice is defined in the header Microsoft.Graphics.Canvas.h
    CanvasVirtualBitmap cvb = pInspectable.as<CanvasVirtualBitmap>();
    return cvb;
  }
}
```

Remember to include the header `<unknwn.h>` in pch.h before any WinRT headers (required in SDK 17763 and later).

Offscreen drawing

Article • 06/29/2024

Apps occasionally need to draw graphics to a target, where that target is not intended for immediate display. This type of drawing is sometimes called "offscreen rendering", or "drawing to a texture". This is useful when, for example, an app's output of a drawing operation is to be saved to a file, returned as an array of pixels, or used as an input to a later operation.

Win2D supports these scenarios, and they are made easy with CanvasRenderTarget.

`CanvasRenderTarget` extends CanvasBitmap, and has the method CreateDrawingSession(). Use `CreateDrawingSession` to draw graphics content to a `CanvasRenderTarget`. For example:

C#

```
CanvasDevice device = CanvasDevice.GetSharedDevice();
CanvasRenderTarget offscreen = new CanvasRenderTarget(device, width, height,
96);

using (CanvasDrawingSession ds = offscreen.CreateDrawingSession())
{
    ds.Clear(Colors.Black);
    ds.DrawRectangle(100, 200, 5, 6, Colors.Red);
}
```

Note that there is a method call to `Clear`. Without this, the bitmap will be initialized with undefined content. Drawing sessions created through `CanvasRenderTarget` are different from those created on Win2D's XAML controls, in terms of the `Clear` behavior. Controls are always cleared automatically by Win2D when a drawing session is created. `CanvasRenderTargets` are not. This way, apps have the ability to make incremental changes to `CanvasRenderTarget`-s, and avoid redrawing an entire scene every time.

To draw a `CanvasRenderTarget` to another drawing session, simply use `DrawImage(ICanvasImage)` or one of its overloads. For example:

C#

```
void canvasControl_Draw(CanvasControl sender, CanvasDrawEventArgs args)
{
    args.DrawingSession.DrawImage(offscreen, 23, 34);
}
```

Or, to use a `CanvasRenderTarget` as an input to an effect, pass it in wherever the effect expects to use an `IGraphicsEffectSource` as a source. For example:

```
C#

GaussianBlurEffect blurEffect = new GaussianBlurEffect()
{
    Source = offscreen,
    BlurAmount = 3.0f
};
```

An app can close, and re-open drawing sessions on a `CanvasRenderTarget` arbitrarily many times.

Drawing operations are not committed to the `CanvasRenderTarget` until the drawing session object is disposed. In C#, a `using` block can organize this.

It's worth pointing out that `CanvasRenderTarget` is not a XAML control, and does not involve the XAML tree at all. It is suitable for both XAML and non-XAML-based apps.

DPI and DIPs

Article • 05/29/2023

This article explains the difference between physical pixels and device independent pixels (DIPs), and how DPI (dots per inch) is handled in Win2D.

Win2D is designed in such a way that many apps can ignore this distinction, as it provides sensible default behaviors that will do the right thing when run on both low and high DPI devices. If your app has more specialized needs, or if you have a different opinion about what "sensible default" means, read on for the gory details...

What is DPI?

DPI stands for "dots per inch". This is an approximate measure of the pixel density of an output display such as a computer monitor or phone screen. The higher the DPI, the more, smaller dots make up the display.

DPI is only an approximate measure because not all display hardware can be relied on to report accurate information. Some computer monitors do not report DPI to the operating system at all, or the user may have configured their system to render using a different DPI from the actual hardware (for instance to change the size of UI text elements). Applications can use DPI to choose how large things should be drawn, but should not rely on it as an exact physical measurement of the display size.

A DPI value of 96 is considered to be a neutral default.

What is a pixel?

A pixel is a single colored dot. Images in computer graphics are made up of many pixels arranged in a two dimensional grid. You can think of pixels as the atoms out of which all images are built.

The physical size of a pixel can vary greatly from one display to another. When a computer is connected to a large but low resolution monitor or external display, pixels can be quite large, but on a phone with a 1080p display only a few inches across, pixels are tiny.

In Win2D, whenever you see an API that specifies a position or size using integer data types (or a struct such as BitmapSize that contains integers), this means the API is operating in pixel units.

Most Win2D APIs work with DIPs rather than pixels.

What is a DIP?

DIP stands for "device independent pixel". This is a virtualized unit that may be the same as, larger, or smaller than a physical pixel.

The ratio between pixels and DIPs is determined by DPI:

```
pixels = dips * dpi / 96
```

When DPI is 96, pixels and DIPs are the same. When using higher DPI, a single DIP may correspond to more than one pixel (or parts of pixels in the common case where DPI is not an exact multiple of 96).

Most Windows Runtime APIs, including Win2D, use DIPs rather than pixels. This has the advantage of keeping graphics approximately the same physical size no matter what display an app is run on. For instance if an app specifies that a button is 100 DIPs wide, when run on a high DPI device such as a phone or 4k monitor this button will automatically scale to be more than 100 pixels in width, so it remains a sensible size that is possible for the user to click on. If the button size was specified in pixels, on the other hand, it would appear ridiculously small on this kind of high DPI display, so the app would have to do more work to adjust layouts differently for each kind of screen.

In Win2D, whenever you see an API that specifies a position or size using floating point data types (or structs such as Vector2 or Size that contain floating point values), this means the API is operating in DIPs.

To convert between DIPs and pixels, use the methods ConvertDipsToPixels(Single, CanvasDpiRounding) and ConvertPixelsToDips(Int32).

Win2D resources that have DPI

All Win2D resources that contain a bitmap image also have an associated DPI property:

- CanvasBitmap
- CanvasRenderTarget
- CanvasSwapChain
- CanvasControl
- CanvasVirtualControl

- CanvasAnimatedControl
- CanvasImageSource

All other resource types are independent of DPI. For instance a single CanvasDevice instance can be used to draw to controls or rendertargets of many different DPIs, therefore the device has no DPI of its own.

Similarly, CanvasCommandList does not have a DPI, because it contains vector drawing instructions rather than a bitmap image. DPI only comes into play during the rasterization process, when the command list is drawn to a rendertarget or control (which do have DPI).

Control DPI

The Win2D controls (CanvasControl, CanvasVirtualControl and CanvasAnimatedControl) automatically use the same DPI as the display the app is running on. This matches the coordinate system used by XAML, CoreWindow, and other Windows Runtime APIs.

If the DPI changes (for instance if the app is moved to a different display), the control will raise the `CreateResources` event and pass a CanvasCreateResourcesReason of DpiChanged. Apps should respond to this event by recreating any resources (such as rendertargets) that depend on the DPI of the control.

Rendertarget DPI

Things that can be drawn onto (which includes not just CanvasRenderTarget but also the rendertarget-like types CanvasSwapChain and CanvasImageSource) have a DPI of their own, but unlike the controls these types are not directly connected to a display, so Win2D cannot automatically determine what the DPI should be. If you are drawing to a rendertarget which will later be copied to the screen, you probably want that rendertarget to use the same DPI as the screen, but if you are drawing for some other purpose (eg. generating images for upload to a website) a default 96 DPI would be more appropriate.

To make both these usage patterns easy, Win2D provides two types of constructor overload:

```
CanvasRenderTarget(ICanvasResourceCreator, width, height, dpi)
CanvasRenderTarget(ICanvasResourceCreatorWithDpi, width, height)
```

The ICanvasResourceCreator interface is implemented by `CanvasDevice` as well as the Win2D controls. Because a device does not have any specific DPI of its own, you must explicitly specify the DPI when creating a rendertarget from one.

For instance to create a default DPI rendertarget where DIPs and pixels will always be the same thing:

```
C#

const float defaultDpi = 96;
var rtWithFixedDpi = new CanvasRenderTarget(canvasDevice, width, height,
defaultDpi);
```

ICanvasResourceCreatorWithDpi extends `ICanvasResourceCreator` by adding a DPI property. This interface is implemented by the Win2D controls, and makes it easy to create a rendertarget which will automatically inherit the same DPI as the control it was created from:

```
C#

var rtWithSameDpiAsDisplay = new CanvasRenderTarget(canvasControl, width,
height);
```

Bitmap DPI

CanvasBitmap, unlike a rendertarget, does not automatically inherit DPI from a control. The methods for creating and loading bitmaps include overloads to explicitly specify DPI, but if you leave this out, bitmap DPI defaults to 96 regardless of the current display configuration.

The reason bitmaps are different to other types is that they are a source of input data, rather than an output which will be drawn onto. So the important thing for bitmaps is not the DPI of where that output will end up, but the DPI of the source image, which is entirely unrelated to the current display settings.

If you load say a 100x100 default DPI bitmap and then draw it onto a rendertarget, the bitmap will be scaled from 100 DIPs at 96 DPI (which is 100 pixels) to 100 DIPs at the DPI of the destination rendertarget (which could be a larger number of pixels if it is a high DPI rendertarget). The resulting image will always be 100 DIPs in size (so there will be no unpleasant layout surprises), but it may suffer some blurring if a low DPI source bitmap was scaled up to a higher DPI destination.

For maximum clarity at high DPI, some applications may wish to provide multiple sets of bitmap images at different resolutions, and at load time select whichever version most closely matches the DPI of the destination control. Other apps may prefer to ship only high DPI bitmaps, and let Win2D scale these down when running on lower DPI displays (scaling down can often look better than scaling up). In either case, the bitmap DPI can be specified as a parameter to LoadAsync(ICanvasResourceCreator, String, Single).

Note that some bitmap file formats contain DPI metadata of their own, but Win2D ignores this since it is often set incorrectly. Instead, DPI must be explicitly specified when loading the bitmap.

CanvasDrawingSession DPI

CanvasDrawingSession inherits its DPI from whatever control, rendertarget, swapchain, etc, it is drawing onto.

By default, all drawing operations operate in DIPs. If you prefer to work in pixels, this can be changed via the Units property.

Effect DPI

The image effect pipeline inherits its DPI from whatever CanvasDrawingSession an effect is being drawn onto. Internally, effect processing always operates in pixels. Parameter values such as sizes or positions are specified in DIPs, but these units are converted to pixels before any actual image manipulation takes place.

When a bitmap of different DPI than the target drawing session is used as an effect source image, an internal DpiCompensationEffect is automatically inserted in between the bitmap and the effect. This scales the bitmap to match the target DPI, which is usually what you want. If it's not what you want, you can insert your own instance of DpiCompensationEffect to customize the behavior.

> **Note**
>
> If implementing a custom effect, consider applying an equivalent DPI handling scheme to ensure consistent behavior when used together with built-in Win2D effects.

Composition API

The `Microsoft.Graphics.Canvas.Composition` APIs operate at a lower level than Win2D XAML controls, so they do not attempt to automatically handle DPI on your behalf. It is up to you to decide what units you prefer to operate in, and set whatever transforms are necessary to achieve that as part of your composition visual tree.

`Windows.UI.Composition` APIs such as `CreateDrawingSurface` always specify sizes in pixel units. When using Win2D to draw onto a composition surface, you can specify whatever DPI you want to use when calling CreateDrawingSession(CompositionDrawingSurface, Rect, Single). All drawing performed through the returned `CanvasDrawingSession` will be scaled up or down accordingly.

How to test DPI handling

The easiest way to test that your app will do the right thing in response to changing display DPI is to run on Windows 10 or Windows 11 and change display settings while the app is running:

- Right-click on the desktop background and choose 'Display settings'
- Move the slider labeled 'Change the size of text, apps, and other items'
- Click the 'Apply' button
- Choose 'Sign out later'

If you do not have Windows 10 or Windows 11, you can also test with the Windows Simulator. In the Visual Studio toolbar, change the "Local Machine" setting to "Simulator", then use the Change Resolution icon to switch the simulated display between:

- 100% (DPI = 96)
- 140% (DPI = 134.4)
- 180% (DPI = 172.8)

Choosing control resolution

Article • 05/29/2023

This article explains how to configure the resolution used by Win2D's XAML controls. It explains how to:

- Make Win2D controls run at a fixed resolution.
- Adjust control DPI to improve performance by rendering fewer pixels.

Resolution and control sizing

"Resolution", as used in this document, is another word for the size of a bitmap. It consists of a width, and height.

The objects that Win2D's XAML controls draw to have a resolution. They also have a DPI. An object's DPI is a measurement of how dense the pixels of that object are, when drawn. DPI behaves like a scale factor- a high DPI increases the number of pixels that comprise the drawn object. On the other hand, lowering the DPI of an object means that it will span fewer pixels. For more information about Win2D's handling of DPI in general, see this page.

DPI-independent size is sometimes called "logical size". And a DPI-dependent size, in pixels, is called "physical size".

In terms of resolution and sizing, a control's default behavior when it's loaded is:

- The control's logical size is determined by its layout, as determined by where it falls in the XAML tree.
- A DPI is queried from the environment. The control's DPI is set to that.
- The amount of physical pixels that comprise the control's drawable area is determined by the control's size, scaled by its DPI.
  - On high DPI, the physical size will be greater (more pixels) compared to the logical size.
  - On low DPI, the physical size will be smaller (fewer pixels) compared to the logical size.
  - On default DPI, the physical size and logical size of the drawable area are the same.
- The control's drawing resource (`CanvasImageSource` for `CanvasControl`, `CanvasVirtualImageSource` for `CanvasVirtualControl` and `CanvasSwapChain` for `CanvasAnimatedControl`) is set to match the size and DPI of the control.

Most Win2D operations are in dips (DPI-independent units), and Win2D's XAML controls' drawing resources are automatically sized to take DPI into account. This means applications can often ignore DPI. Sizes and co-ordinates are always DPI-independent unless specified otherwise. An application can hard-code various sizes and co-ordinates at which things are drawn into the controls, and that content gets scaled when the app is run in environments with different DPIs.

But for some applications, the default behavior isn't sufficient. This article outlines a couple scenarios where the default is not sufficient, and what apps can do to fix it.

Scenario: the control's contents must be a fixed, lower-than-normal resolution

This scenario may arise, for instance, on a 2D sprite game that should always render at a fixed 640x480 resolution, regardless of what actual display hardware it is run on.

Solving this doesn't strictly require writing any new Win2D code at all.

The Viewbox XAML object lets you constrain the sizes of its child visual elements, automatically adding scaling, with letterboxing or pillarboxing to preseve aspect ratios as necessary.

Simply ensure your `CanvasControl`, `CanvasVirtualControl` or `CanvasAnimatedControl` is a child element of a `ViewBox`, and restrict the size of that control.

For example, to constrain the size of the control to 320 pixels wide, and 224 pixels high, regardless of DPI, then instead of:

XAML

```
<canvas:CanvasAnimatedControl/>
```

Use:

XAML

```
<Viewbox>
    <canvas:CanvasAnimatedControl  Width="320" Height="224"/>
</Viewbox>
```

If your app should not preserve the aspect ratio by adding letterboxing/pillarboxing, then add the `Stretch` attribute:

XAML

```
<Viewbox Stretch="Fill">
    <canvas:CanvasAnimatedControl Width="320" Height="224"/>
</Viewbox>
```

Note that the scaling performed by the `Viewbox` element does not guarantee any control over the interpolation mode. The filtering method may look like `CanvasInterpolationMode.Linear`, or something similar. If your app needs a particular interpolation mode, then don't use `ViewBox` with a fixed-size control. Instead, draw to an intermediate, fixed-size `CanvasRenderTarget`, and use the desired interpolation mode to draw the scaled intermediate to the target.

Scenario: the app cannot perform well at high resolutions

Some devices have very high-resolution displays, but their graphics processing unit is not powerful enough to animate that many pixels smoothly. Developers may not be readily aware of how their apps perform on these devices without testing them.

One option is to use the `DpiScale` property of the control to reduce the control's DPI.

For example, to fix the control at half-resolution, use:

XAML

```
<canvas:CanvasAnimatedControl DpiScale="0.5" />
```

The actual DPI scale factor depends upon the needs of your app. One option is to compute a scale factor that will fix the app's DPI at 96, and no higher.

For example:

C#

```
float dpiLimit = 96.0f;

if(control.Dpi > dpiLimit)
{
    control.DpiScale = dpiLimit / control.Dpi;
}
```

To ensure this setting works across DPI changes, the application should subscribe to DisplayInformation.DpiChanged and use this logic in the handler to set the DPI scale against the new DPI.

This saves the app some perf overhead, exploiting the fact that users may not be able to easily percieve the reduced resolution on a high-DPI display.

The scaling performed in having a lower-than-native resolution control resource cannot guarantee control over the interpolation mode, similar to `ViewBox` mentioned above. If your app needs a particular interpolation mode, use an intermediate instead.

Pixel formats

Article • 05/29/2023

The [`DirectXPixelFormat`](https://msdn.microsoft.com/library/windows/apps/windows.graphics.directx.directxpixelformat.aspx) enum includes all the many and varied pixel formats used by Direct3D and DXGI, but only a few of these options are supported by Win2D (or by Direct2D upon which Win2D is built).

If in doubt, pixel format `B8G8R8A8UIntNormalized` and CanvasAlphaMode.Premultiplied are good defaults for most purposes.

All the formats listed below are supported by Direct3D feature level 11 GPU hardware (used in desktop computers and most tablets). Feature level 9 GPUs (which are found in phones) only support a subset.

> **Note**
>
> If you want to use one of the formats marked as "Not supported on all devices", you should first check **IsPixelFormatSupported(DirectXPixelFormat)**, or catch exceptions if the resource creation fails and be prepared to fall back on one of the universally available options.

CanvasBitmap formats

`DirectXPixelFormat`	**Compatible CanvasAlphaMode-s**	**Notes**
`B8G8R8A8UIntNormalized`	`Premultiplied`, `Ignore`	The default format
`B8G8R8A8UIntNormalizedSrgb`	`Premultiplied`, `Ignore`	Not supported on all devices
`B8G8R8X8UIntNormalized`	`Ignore`	
`R8G8B8A8UIntNormalized`	`Premultiplied`, `Ignore`	
`R8G8B8A8UIntNormalizedSrgb`	`Premultiplied`, `Ignore`	Not supported on all devices
`R16G16B16A16Float`	`Premultiplied`, `Ignore`	Not supported on all devices
`R32G32B32A32Float`	`Premultiplied`, `Ignore`	Not supported on all devices

`DirectXPixelFormat`	**Compatible CanvasAlphaMode - s**	**Notes**
`R10G10B10A2UIntNormalized`	`Premultiplied`, `Ignore`	Not supported on all devices
`R16G16B16A16UIntNormalized`	`Premultiplied`, `Ignore`	Not supported on all devices
`R8G8UIntNormalized`	`Ignore`	Not supported on all devices. Bitmaps of this format can be used as effect sources, but are not directly drawable.
`R8UIntNormalized`	`Ignore`	Not supported on all devices. Bitmaps of this format can be used as effect sources, but are not directly drawable.
`A8UIntNormalized`	`Premultiplied`, `Straight`	Bitmaps of this format can be used as opacity masks or effect sources, but are not directly drawable.
`BC1UIntNormalized`	`Premultiplied`, `Ignore`	
`BC2UIntNormalized`	`Premultiplied`, `Ignore`	
`BC3UIntNormalized`	`Premultiplied`, `Ignore`	

CanvasRenderTarget formats

`DirectXPixelFormat`	**Compatible CanvasAlphaMode - s**	**Notes**
`B8G8R8A8UIntNormalized`	`Premultiplied`, `Ignore`	The default format
`B8G8R8A8UIntNormalizedSrgb`	`Premultiplied`, `Ignore`	Not supported on all devices
`R8G8B8A8UIntNormalized`	`Premultiplied`, `Ignore`	
`R8G8B8A8UIntNormalizedSrgb`	`Premultiplied`, `Ignore`	Not supported on all devices
`R16G16B16A16Float`	`Premultiplied`, `Ignore`	Not supported on all devices
`R32G32B32A32Float`	`Premultiplied`, `Ignore`	Not supported on all devices
`R16G16B16A16UIntNormalized`	`Premultiplied`, `Ignore`	Not supported on all devices

`DirectXPixelFormat`	**Compatible CanvasAlphaMode -s**	**Notes**
`A8UIntNormalized`	`Premultiplied`, `Straight`	

CanvasSwapChain formats

`DirectXPixelFormat`	**Compatible CanvasAlphaMode -s**	**Notes**
`B8G8R8A8UIntNormalized`	`Premultiplied`, `Ignore`	The default format
`R8G8B8A8UIntNormalized`	`Premultiplied`, `Ignore`	
`R16G16B16A16Float`	`Premultiplied`, `Ignore`	Not supported on all devices

Premultiplied alpha

Article • 05/29/2023

In computer graphics there are two different ways to represent the opacity of a color value. Win2D uses both methods. This article explains the difference, and which is used where.

Straight alpha

When using straight, also known as linear, alpha:

- RGB values specify the color of the thing being drawn
- The alpha value specifies how solid it is

In this world, RGB and alpha are independent. You can change one without affecting the other. To make an object fade out, you would gradually reduce its alpha value while leaving RGB unchanged.

To perform a source-over blend between two colors that use straight alpha format:

```
result = (source.RGB * source.A) + (dest.RGB * (1 - source.A))
```

Premultiplied alpha

When using premultiplied alpha:

- RGB specifies how much color the thing being drawn contributes to the output
- The alpha value specifies how much it obscures whatever is behind it

In this world, RGB and alpha are linked. To make an object transparent you must reduce both its RGB (to contribute less color) and also its alpha (to obscure less of whatever is behind it). Fully transparent objects no longer have any color at all, so there is only one value that represents 100% transparency: RGB and alpha all zero.

To perform a source-over blend between two colors that use premultiplied alpha format:

```
result = source.RGB + (dest.RGB * (1 - source.A))
```

Premultiplied alpha is used in graphics rendering because it gives better results than straight alpha when filtering images or composing different layers. For more information see these blog posts:

- Premultiplied alpha
- Premultiplied alpha and image composition

Alpha in Win2D

Win2D uses straight alpha in its API surface, but premultiplied alpha for internal rendering operations.

`Windows.UI.Color` values use straight alpha. Whenever you pass a color to a `Draw*` or `Fill*` method, set the color of a brush, or clear to a color value, this color is specified using straight alpha.

The pixel values stored in a bitmap or rendertarget, and the drawing or blending operations that operate on these surfaces, use premultiplied alpha. When bitmaps are loaded from a file their contents are automatically converted into premultiplied format. When you call a Win2D drawing method, its color parameter is converted from straight to premultiplied before the actual drawing takes place.

Win2D image effects use a mixture of straight and premultiplied alpha. Some effects operate on one format, some on the other, and some provide a property to choose. The documentation for each effect type describes which alpha mode it uses. Effect input data is always assumed to be premultiplied, so when an effect needs to work with straight alpha it will first apply an unpremultiply transform, compute the effect, and then re-premultiply the output.

The bitmap APIs `GetPixelBytes`, `SetPixelBytes`, `GetPixelColors`, and `SetPixelColors`, do **not** perform any alpha format conversions. They just directly transfer bit values to or from the underlying GPU texture. This allows you to observe what alpha format Win2D is using internally:

- Create a drawing session on a rendertarget
- Call `drawingSession.Clear(Colors.Tranparent)`
- `Colors.Tranparent` is defined as R = 255, G = 255, B = 255, A = 0
- Win2D will convert this value to premultiplied format, yielding R = 0, G = 0, B = 0, A = 0
- Use `GetPixelColors` to read back the contents of the rendertarget
- Observe that it contains premultiplied format RGB = 0, not RGB = 255 like the original straight alpha `Colors.Tranparent` value

Converting between alpha formats

To convert a straight alpha color value to premultiplied format, multiply its R, G, and B values by A. To convert premultiplied to straight, divide R, G, and B by A.

Note that color information is often represented as byte values ranging from 0 to 255 (for example the `Windows.UI.Color` structure consists of 4 bytes). This representation is scaled up by a factor of 255, so a byte value of 255 actually means 1, while 128 is half intensity. That scaling factor must be taken into account during format conversions, so to convert a `Windows.UI.Color` from straight to premultiplied:

C#

```
premultiplied.R = (byte)(straight.R * straight.A / 255);
premultiplied.G = (byte)(straight.G * straight.A / 255);
premultiplied.B = (byte)(straight.B * straight.A / 255);
premultiplied.A = straight.A;
```

If you have image data that is using the wrong alpha format, PremultiplyEffect or UnPremultiplyEffect can be used to convert it.

Bitmap block compression

Article • 05/29/2023

`CanvasBitmap` supports block compressed bitmaps. These can be loaded from a DDS file, or created with CreateFromBytes(ICanvasResourceCreator,Byte[], Int32, Int32, DirectXPixelFormat).

Block compressed bitmaps are great for bitmap heavy applications (such as games) because they take up less memory and can be drawn more efficiently. A block compressed bitmap uses up to 1/8th of the memory of an uncompressed bitmap. As a result, the GPU needs to access much less memory when drawing the bitmap, resulting in faster drawing.

About block compression

Block compression is different to the compression employed by PNG or JPG files. Compressed file formats are stored compressed but when they are loaded by Win2D they are decompressed into a bitmap with a format such as `DirectXPixelFormat::B8G8R8A8UIntNormalized`, which uses 32 bits (4 bytes) per pixel. So a 256x256 bitmap would take up 256 * 256 * 4 = 262,144 bytes.

A block compressed bitmap uses 8 or 16 bytes (depending on the format -- more on this later) to store a block of 4x4 pixels. So in this case a 256x256 bitmap would take up 256 * 256 / (4 * 4) * 8 = 32,768 bytes, or 256 * 256 / (4 * 4) * 16 = 65,536 bytes. That's up to 8 times smaller! Since block compression is supported directly by the GPU hardware, the bitmap can be kept compressed in memory and drawn directly from the compressed format without ever having to completely uncompress it.

Win2D supports three block compressed formats. The table below describes these formats, along with an uncompressed format for comparison.

`DirectXPixelFormat`	**Size of 4x4 bitmap**	**Size of 256x256 bitmap**	**Alpha**
`BC1Unorm`	8 bytes	32,768 bytes	1 bit
`BC2Unorm`	16 bytes	65,536 bytes	4 bit
`BC3Unorm`	16 bytes	65,536 bytes	~8 bit (compressed)
`B8G8R8A8UintNormalized`	64 bytes	262,144 bytes	8 bit

`BC1Unorm`, `BC2Unorm` and `BC3Unorm` differ mostly in how they support alpha. BC1 supports only 1-bit alpha. BC2 supports each pixel in the block having a unique 4-bit alpha value. BC3 compresses the alpha values.

See Direct2D Block Compression documentation and Direct3D Block Compression documentation for more information about how block compression works.

Restrictions

- All block compressed textures must have a width and height that is a multiple of 4. This is because block compression works on blocks of 4x4 pixels.
- Any operation on a sub-rectangle of a block compressed texture (using `GetPixelBytes()`, `SetPixelBytes(Byte[])`, `CopyPixelsFromBitmap(CanvasBitmap, Int32, Int32)`) require that the sub-rectangle is 4-pixel aligned.
- Win2D requires premultiplied alpha when using block compressed formats.

Authoring DDS files

Block compressed images can be saved in DDS files. Although these can be generated by plugins to applications such as Photoshop or Paint.NET, care must be taken to ensure that the resulting file is saved with premultiplied alpha. Win2D will load any DDS file containing a `BC1Unorm`, `BC2Unorm` or `BC3Unorm` image and assume that it is authored with premultiplied alpha.

If you are authoring a C++ project then you can use the Image Content Pipeline to convert the image, as described on MSDN.

Alternatively, you can use `texconv.exe` from https://github.com/Microsoft/DirectXTex. `texconv.exe` can be built using the DirectXTex_Desktop_2015.sln solution. The following command converts "smoke.png" to a `BC3Unorm` with premultiplied alpha:

Windows Command Prompt

```
texconv -pmalpha -m 1 -f BC3_UNORM smoke.png
```

Effect precision and clamping

Article • 05/29/2023

Care must be taken while rendering effects using Win2D to achieve the desired level of quality and predictability with respect to numerical precision.

You need to understand these details if:

1. Your effect graph relies on high numerical precision or colors outside of the [0, 1] range, and you want to make sure these will always be available.
2. Or your effect graph relies on the rendering implementation to clamp intermediate colors to the [0, 1] range, so you must ensure this clamping always occurs.

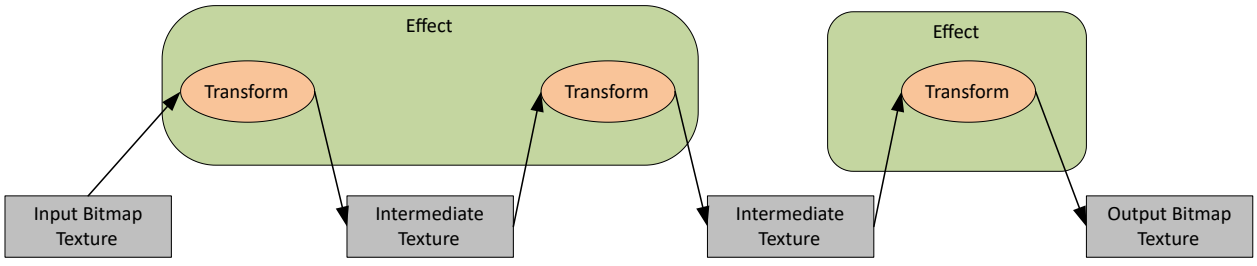
Win2D often divides an effect graph into sections, and renders each section in a separate step. The output of some steps may be stored in intermediate Direct3D textures which by default have limited numerical range and precision. Win2D makes no guarantees about if or where these intermediate textures are used. This behavior may vary according to GPU capabilities as well as between Windows versions.

In Windows 10, Win2D uses fewer intermediate textures due to its use of shader linking. Win2D may therefore produce different results with default settings than in prior Windows releases. This primarily affects scenarios where shader linking is possible in an effect graph, and that graph also contains effects that produce extended-range output colors.

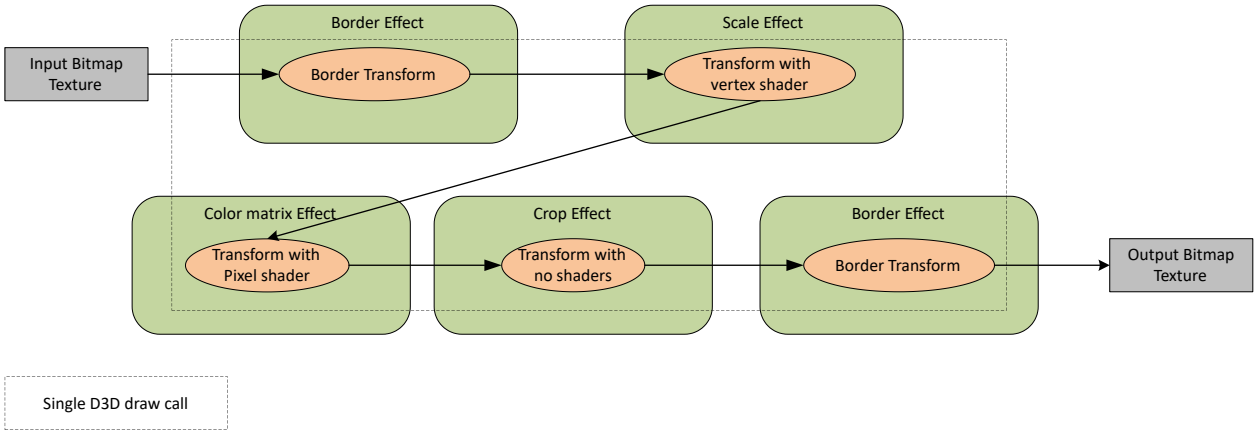
Overview of effect rendering and intermediates

To render an effect graph, Win2D first finds the underlying graph of "transforms", where a transform is a graph node used within an effect to apply a specific processing operation. Each image effect may internally be implemented using one or several transforms. There are different types of transforms, including those which provide Direct3D shaders for Direct2D to use.

For example, Win2D may render an effect graph as follows:

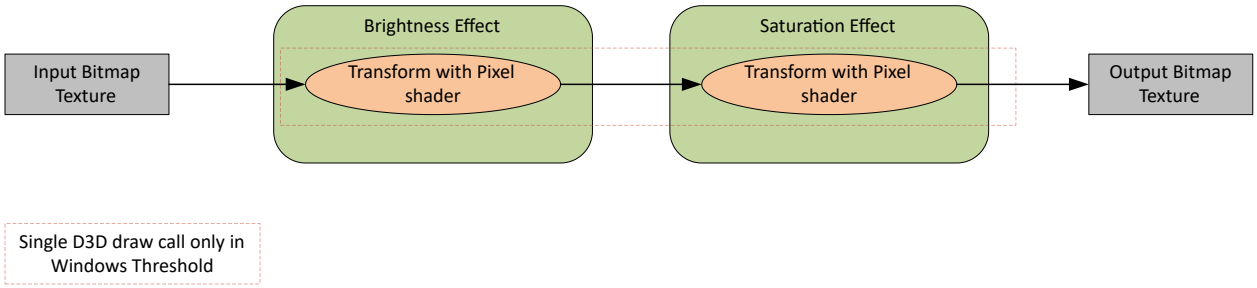


Win2D looks for opportunities to avoid using intermediate textures. This logic is opaque to applications, and may reduce the number of intermediate textures used. For example, the following graph can be rendered by Win2D using one Direct3D draw call and no intermediate textures:



Prior to Windows 10, Win2D would always use intermediate textures if multiple pixel shaders were used within the same effect graph. Most built-in effects that simply adjust color values (for example, Brightness or Saturation) do so using pixel shaders.

In Windows 10, Win2D may now avoid using intermediate textures in such cases. It does this by internally linking adjacent pixel shaders. For example:



Note that not all adjacent pixel shaders in a graph may be linked together, and therefore only certain graphs will produce different output on Windows 10. For full details see Effect Shader Linking. The primary restrictions are:

- An effect will not be linked with effects consuming its output, if the first effect is connected as an input to multiple effects.
- An effect will not be linked with an effect set as its input, if the first effect samples its input at a different logical position than its output. For example, a `ColorMatrix` effect might be linked with its input, but a `Convolution` effect will not be.

Built-in effect behavior

Many built-in effects may produce colors outside of the [0, 1] range in unpremultiplied space, even when their input colors are within that range. When this happens, such colors may be subject to numerical clamping. Note that it's important to consider the color range in unpremultiplied space, even though built-in effects typically produce colors in premultiplied space. This ensures that colors stay within range, even if other effects subsequently unpremultiply them.

Some of the effects which emit these out-of-range colors offer a `ClampOutput` property. These include:

- `ColorMatrix`
- `ArithmeticComposite`
- `Convolve`
- `Transfer` effects

Setting the `ClampOutput` property to true on these effects ensures a consistent result will be achieved regardless of factors such as shader linking. Note that clamping occurs in unpremultiplied space.

Other built-in effects may also produce output colors beyond the [0, 1] range in unpremultiplied space, even when their color pixels (and `Color properties if any) are within that range. These include:

- `Transform` and `Scale` effects (when the `InterpolationMode` property is `Cubic` or `HighQualityCubic`)
- Lighting effects
- `EdgeDetection` (when the `OverlayEdges` property is `true`)
- `Exposure`
- `Composite` (when the `Mode` property is `Add`)
- `Saturation`
- `Sepia`
- `TemperatureAndTint`

Forcing numerical clamping within an effect graph

While using effects listed above which do not have a `ClampOutput` property, applications should consider forcing numerical clamping. This can be done by inserting an additional effect into the graph that clamps its pixels. A `ColorMatrix` effect may be used, with its `ClampOutput` property set to `true`.

A second option to achieve consistent results is to request that Win2D use intermediate textures which have greater precision. This is described below.

Controlling precision of intermediate textures

Win2D provides a few ways to control the precision of a graph.

Before using high precision formats in Win2D, applications must ensure they are supported sufficiently by the GPU. To check this, use IsBufferPrecisionSupported(CanvasBufferPrecision).

Applications may create a Direct3D device using WARP (software emulation) to ensure that all buffer precisions are supported. This is recommended in scenarios such as applying effects to a photo while saving to disk. Even if Win2D supports high precision buffer formats on the GPU, using WARP is recommended in this scenario on feature level 9.X GPUs, due to limited precision of shader arithmetic and sampling on some low-power mobile GPUs. To use software rendering, specify `ForceSoftwareRenderer = true` on your Win2D XAML controls or when creating your `CanvasDevice`.

In each case below, the requested precision is actually the minimum precision Win2D will use. Higher precision may be used if intermediates are not required. Win2D may also share intermediate textures for different parts of the same graph or different graphs entirely. In this case Win2D uses the maximum precision requested for all involved operations.

Precision selection from the drawing session

The simplest way to control the precision of Win2D's intermediate textures is to use the EffectBufferPrecision property. This controls the precision of all intermediate textures, as long as a precision is not also set manually on effects directly.

C#

```
if
(canvasDevice.IsBufferPrecisionSupported(CanvasBufferPrecision.Precision32Fl
oat))
{
    drawingSession.EffectBufferPrecision =
CanvasBufferPrecision.Precision32Float;
}
```

Precision selection from inputs and render targets

Applications may also rely on the precision of the inputs to an effect graph to control the precision of intermediate textures.

The precisions of inputs to effects are propagated through the graph to select the precision of downstream intermediates. Where different branches in the effect graph meet, the greatest precision of any input is used.

The precision selected based on a Win2D bitmap is determined from its pixel format.

It is possible that Win2D cannot assign an effect a precision based on its inputs. This happens when an effect has no inputs, or when a command list is used, which has no specific precision. In this case, the precision of intermediate textures is determined from the current render target.

Precision selection directly on effects

The minimum precision for intermediate textures may also be set at explicit locations within an effect graph. This is only recommended for advanced applications.

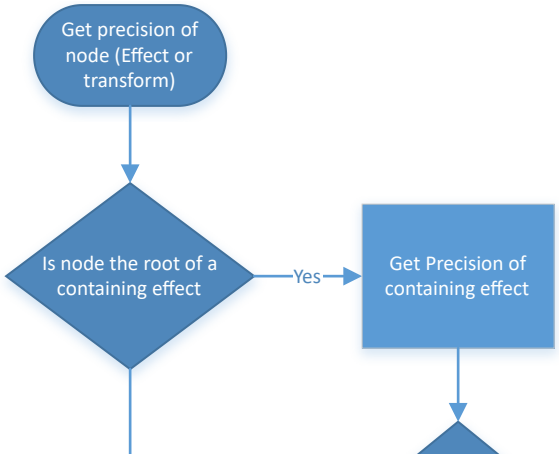
The minimum precision may be set using a property on an effect as follows:

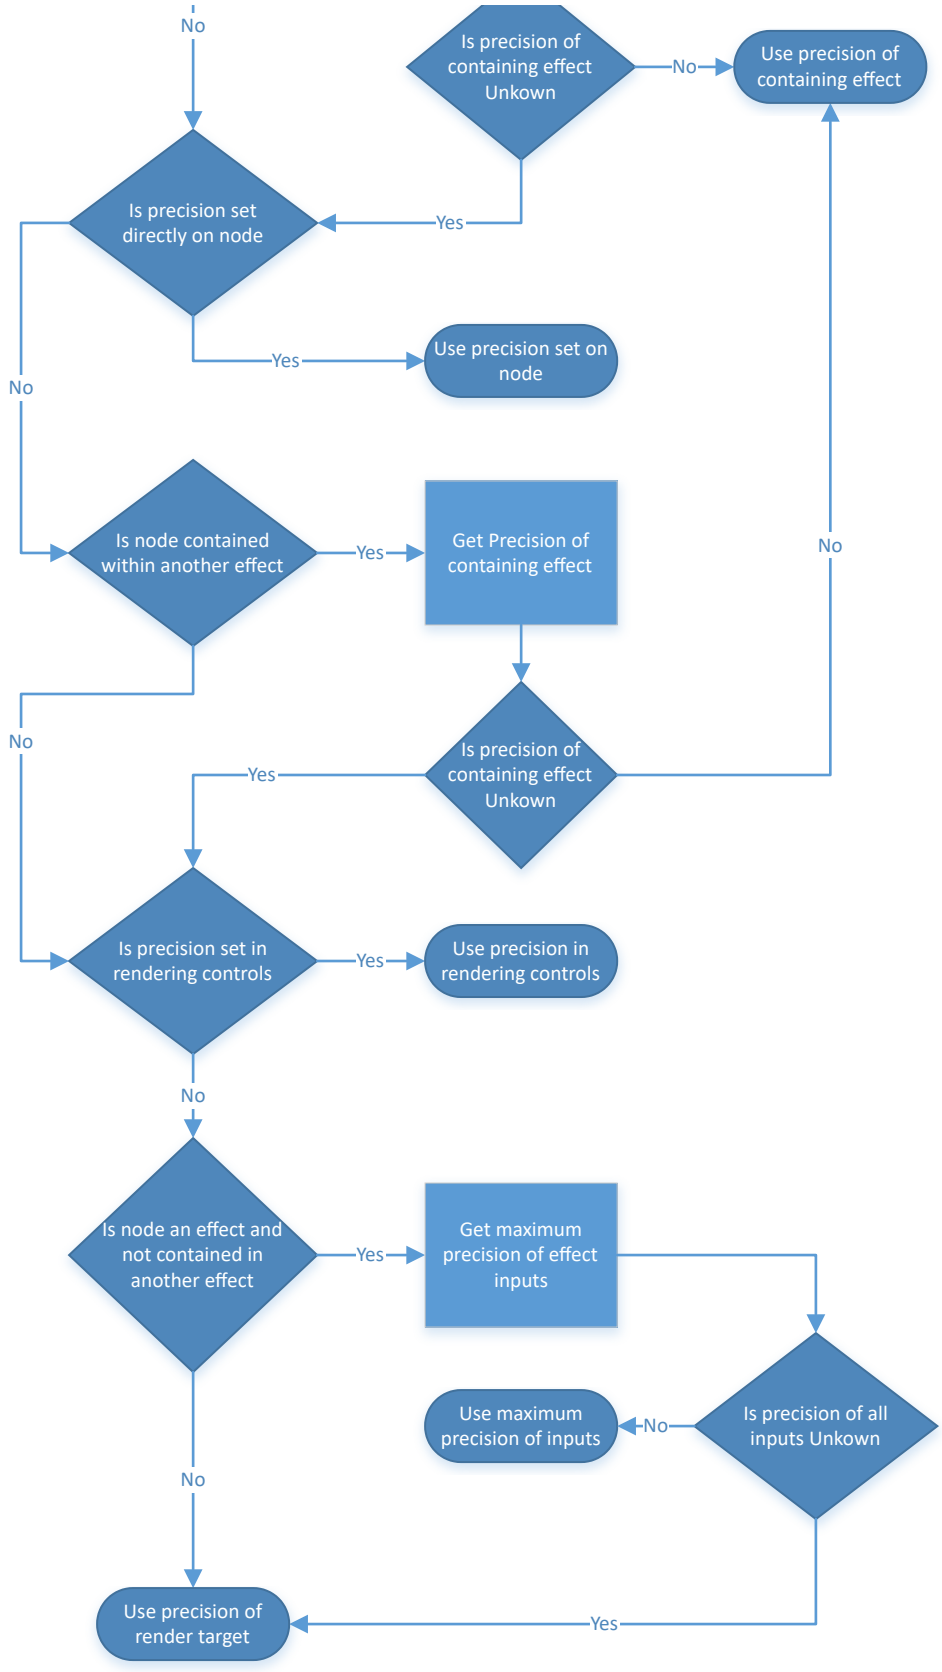
C#

```
if
(canvasDevice.IsBufferPrecisionSupported(CanvasBufferPrecision.Precision32Fl
oat))
{
    blurEffect.BufferPrecision = CanvasBufferPrecision.Precision32Float;
}
```

Note that the precision set on an effect will also apply to effects downstream in the same effect graph, unless a different precision is set on those downstream effects.

Below is the full recursive logic used to determine the minimum precision for an intermediate buffer storing the output of a given transform node:





No
Is precision of containing effect Unkown
No
Use precision of containing effect
Is precision set directly on node
Yes
Yes
Use precision set on node
No
Is node contained within another effect
Yes
Get Precision of containing effect
No
No
Is precision of containing effect Unkown
Yes
Is precision set in rendering controls
Yes
Use precision in rendering controls
No

Handling device lost

Article • 05/29/2023

"Device lost" refers to a situation where the GPU graphics device becomes unusable for further rendering. This can occur due to GPU hardware malfunction, driver bugs, driver software updates, or switching the app from one GPU to another. A lost device can no longer be used, and any attempt to do so from Win2D will throw an exception. To recover from this situation, the app must create a new device and then recreate all its graphics resources.

Not all apps bother trying to recover from device lost. This is a (hopefully!) rare situation, so some developers will just let their apps crash if it occurs. For those who prefer to handle device lost in a robust way, this article explains how.

Device lost when using XAML controls

The Win2D controls (CanvasControl, CanvasVirtualControl and CanvasAnimatedControl) attempt to automatically handle device lost on behalf of the app.

When device lost is detected, these controls will recreate their `CanvasDevice` and then raise the `CreateResources` event passing a CanvasCreateResourcesReason of NewDevice. Apps should respond to this event by recreating all their graphics resources using the new device, and updating any data structures that may contain references to the old, no-longer-valid resources.

The controls can automatically catch and handle device lost exceptions that are thrown by their `CreateResources`, `Update`, `Draw`, or `RegionsInvalidated` event handlers. If you call Win2D drawing APIs from other places (for instance in a pointer or keyboard input event handler) then see the next section.

Manually handling device lost

If you are using Win2D without the built-in controls or from outside the `CreateResources`, `Update` or `Draw` event handlers, then it is your responsibility to catch and report lost device exceptions. This is done with the IsDeviceLost(Int32) and RaiseDeviceLost() methods:

```
C#
```

```
try
{
    DrawStuff();
}
catch (Exception e) where canvasDevice.IsDeviceLost(e.ErrorCode)
{
    canvasDevice.RaiseDeviceLost();
}
```

Calling `RaiseDeviceLost` tells any controls that are sharing this device to initiate their lost device recovery path. If you got your device from somewhere other than a control, use the DeviceLost event to be informed when it is lost.

How to test device lost handling

The easiest way to test that your app will do the right thing in response to device lost is to disable your hardware GPU while the app is running:

- Open Device Manager (Explorer window -> right-click 'This PC' -> 'Properties' -> 'Device Manager')
- Expand the 'Display adapters' node
- Right-click the entry for your GPU and click 'Disable' This will bypass your hardware GPU, at which point Windows switches over to a WARP software rendering device, and all active apps experience a device lost.

Don't forget to reenable your GPU after performing this test! If you want to test device lost more than once, it's best to restart your app each time (always launch it with the GPU enabled). Repeatedly toggling the GPU on and off while an app is running doesn't reliably cause lost devices as it may just continue using the WARP software device.

While testing lost device handling, you probably also want to make sure your app deals correctly with dynamic display DPI changes.

Using Win2D without built-in controls

Article • 05/29/2023

CanvasControl, CanvasVirtualControl and CanvasAnimatedControl are XAML controls - they extend `UserControl` and can exist alongside other controls in an app's XAML tree. They are good choice for many WinRT apps that use XAML and produce graphical content using Win2D. While these controls are versatile, they do impose policies pertaining to layout, resource re-creation, and device lost. Apps may want to implement their own XAML controls, or not use XAML at all.

Win2D is built to support this. This document describes how to use Win2D to draw graphics without use of `CanvasControl`, `CanvasVirtualControl` or `CanvasAnimatedControl`.

Layering

The Win2D XAML controls are built of top of a low level Win2D type. Each control contains an instance of a lower-level type:

Expand table

Control	Low-level type
`CanvasControl`	CanvasImageSource
`CanvasVirtualControl`	CanvasVirtualImageSource
`CanvasAnimatedControl`	CanvasSwapChainPanel and CanvasSwapChain

The controls consume only the public interfaces of these lower-level types. This implementation detail lends some confidence that apps can implement their own XAML controls which are equivalently as powerful as the built-in Win2D controls.

Choosing a lower-level type

An application is free to bypass the provided Win2D XAML controls and use the lower-level types directly. This section provides some guidance on choosing the appropriate lower-level type.

If there is existing C++ code that works with `IDXGISwapChain` then C++ interop can be used to wrap this with a `CanvasSwapChain`. `CanvasSwapChainPanel` can be used to display

a `CanvasSwapChain` in a XAML app.

If the app needs to add graphics to a XAML element which expects an ImageSource, it should use `CanvasImageSource` or `CanvasVirtualImageSource`.

Aside from that, it's worth considering:

- Swap chains are suited for content which will animate very frequently and the animation should be smooth. Direct3D's swap chains are designed for this purpose. The content of a swap chain can be re-drawn with a low latency, as it is not tied to the XAML framework refresh timer.
- `CanvasSwapChain` has heavier resource costs than `CanvasImageSource`. It is generally not desirable to have more than one or two swap chains onscreen at a time. For example, if an application has a page full of widgets, where each widget is a standalone graphical element, it is more appropriate to make each widget use a `CanvasImageSource` resource than a `CanvasSwapChain`.
- `CanvasImageSource` can be manipulated by other XAML UI elements such as transforms or opacity changes, while `CanvasSwapChain` cannot.
- `CanvasVirtualImageSource` can be used to display images that are much larger than the screen (for example in a `ScrollViewer`).

CanvasSwapChain and CoreWindow

CanvasSwapChain wraps a Direct3D swap chain. `CanvasSwapChain` is not a XAML type, but the fact that it has a swap chain means it has a built-in mechanism for being displayed. That said, CoreWindow apps may use `CanvasSwapChain` for displaying graphical content.

To create a `CanvasSwapChain` for use with a `CoreWindow`, in C#:

```
C#

float currentDpi = DisplayInformation.GetForCurrentView().LogicalDpi;

SwapChain = CanvasSwapChain.CreateForCoreWindow(device, window, currentDpi);
```

To draw content using a `CanvasSwapChain`, call its CreateDrawingSession(Color) method:

```
C#

using (CanvasDrawingSession ds =
swapChain.CreateDrawingSession(Colors.Black))
```

```
{
    ds.FillRectangle(100, 200, 3, 5);
}

swapChain.Present();
```

The size of the swap chain should match the size of the `CoreWindow`. If the size of the window changes, call ResizeBuffers(Size) on the swap chain with the new size. For more information, see the `CoreWindow` Win2D sample.

> **Note**
>
> `CoreWindow` is only supported on UWP. For WinAppSDK apps, use either composition or HWND swapchains.

CanvasSwapChainPanel

CanvasSwapChainPanel is a XAML type, and a relatively thin wrapper around `CanvasSwapChain`. It is suitable for XAML apps that require swap chain rendering, but do not want to use the policies that exist in `CanvasAnimatedControl`. To create a swap chain in XAML, use the namespace:

XAML

```
xmlns:canvas="using:Microsoft.Graphics.Canvas.UI.Xaml"
```

And declare:

XAML

```
<canvas:CanvasSwapChainPanel x:Name="canvasSwapChainPanel"/>
```

A `CanvasSwapChainPanel` does not have a swap chain automatically assigned to it. As an example, to assign one:

C#

```
CanvasDevice device = CanvasDevice.GetSharedDevice();
CanvasSwapChain swapChain = new CanvasSwapChain(device, width, height, 96);

canvasSwapChainPanel.SwapChain = swapChain;
```

To draw to the swap chain panel, in C#, use its `SwapChain` property:

```
C#

using (CanvasDrawingSession ds =
canvasSwapChainPanel.SwapChain.CreateDrawingSession(Colors.Black))
{
    ds.FillRectangle(200, 300, 5, 6, Colors.Blue);
}

canvasSwapChainPanel.SwapChain.Present();
```

The application decides on the frequency of redrawing. In the same manner as using `CanvasSwapChain` directly, it is up to the app to resize the swap chain when the control is resized. For example, in C#:

```
C#

canvasSwapChainPanel.SizeChanged += canvasSwapChainPanel_SizeChanged;

void canvasSwapChainPanel_SizeChanged(object sender,
Windows.UI.Xaml.SizeChangedEventArgs e)
{
    canvasSwapChainPanel.SwapChain.ResizeBuffers(e.NewSize);
}
```

Image Sources

CanvasImageSource and CanvasVirtualImageSource provide a way of integrating Win2D graphical content with XAML. They are suitable for content which does not require swap chain rendering.

CanvasImageSource

CanvasImageSource extends XAML's SurfaceImageSource. Apps can create an instance of `CanvasImageSource`, and reference it from a XAML type that consumes an `ImageSource`, such as an Image or ImageBrush. For example, in XAML markup:

```
XAML

<Image x:Name="image"/>
```

Then, in C#:

C#

```
CanvasDevice device = CanvasDevice.GetSharedDevice();
CanvasImageSource imageSource = new CanvasImageSource(device, width,
height);

image.Source = imageSource;
```

Drawing sessions are created directly on the image source object. For example:

C#

```
using (CanvasDrawingSession ds =
imageSource.CreateDrawingSession(Colors.Black))
{
    ds.FillRectangle(200, 300, 5, 6, Colors.Blue);
}
```

Note that a clear color must be passed to `CreateDrawingSession`. Whenever a drawing session is created on a `CanvasImageSource`, the `CanvasImageSource` is cleared.

For an example demonstrating how to use `CanvasImageSource`, see the `ImageSourceUpdateRegion` Win2D ExampleGallery page.

CanvasVirtualImageSource

CanvasVirtualImageSource wraps XAML's VirtualSurfaceImageSource.

The wrapped `VirtualSurfaceImageSource` can be obtained by the Source property. Apart from this difference it can be used in much the same way as `CanvasImageSource`:

XAML

```
<Image x:Name="image"/>
```

C#

```
var virtualImageSource = new CanvasVirtualImageSource(device, width,
height);

image.Source = virtualImageSource.Source;
```

CanvasRenderTarget

`CanvasRenderTarget` represents a drawable bitmap, and does not have any built-in association with XAML. It is suitable for XAML or non-XAML apps which need to use an intermediate bitmap- for example, for saving image data to a file, reading back pixel data, or to be used as an intermediate for another operation.

`CanvasRenderTarget` doesn't have an automatic mechanism to cause it to be displayed. To display the content of a `CanvasRenderTarget` in your app, draw it in the drawing session created from a displayed control, image source, or swap chain.

For more information about using `CanvasRenderTarget`, see Offscreen drawing.

Loading resources outside of CreateResources

Article • 05/29/2023

This document discusses how apps using Win2D's XAML controls, CanvasControl, CanvasVirtualControl and CanvasAnimatedControl, can load resources from outside the CreateResources handler.

Resource loading and CanvasControl / CanvasVirtualControl

Normally, apps are expected to use the `CreateResources` handler for creating controls' resources, so that device dependent resources are re-recreated as necessary if the device is lost. This includes resources that are loaded asynchronously. For asynchronous resource loading, controls are encouraged to use TrackAsyncAction(IAsyncAction) with `CreateResources` to ensure correct behavior.

All of this works well for cases where all resources are loaded at startup only.

But, what about apps which need to load some resources at startup, and some other resources later? For example, consider a game with different levels, and the levels need different graphical assets. Win2D doesn't have something built-in with `CreateResources` to enable this- an app cannot manually tell a control, "Re-issue `CreateResources` now, so that I can load different assets from before". However, the building blocks are there to make this work, and allow very good flexibility for how and when the resources are loaded, and be robust with respect to lost device.

Really, what an app wants to do in this case, is have a custom `LoadResourcesForLevelAsync` method, a "custom" `CreateResources`-launched task, like this:

C#

```
async Task LoadResourcesForLevelAsync(CanvasControl resourceCreator, int
level)
{
    levelBackground = await CanvasBitmap.LoadAsync(resourceCreator, ...);
    levelThingie = await CanvasBitmap.LoadAsync(resourceCreator, ...);
    // etc.
}
```

The app needs to load some of its resources after `CreateResources` is completed. In particular, the app will issue the level load after `CreateResources` has completed - e.g., from its `Draw` handler. In the code below, the app's `Draw` handler controls the progress of its level-loading Task.

To make `CreateResources` work in this situation, and be robust against lost devices, an app needs to do four things:

1. Track when `LoadResourcesForLevelAsync` is in progress.
2. Allow Win2D to handle any exceptions (in particular, device lost) that the app doesn't know how to handle.
3. If Win2D raises the `CreateResources` event to recover from a lost device while `LoadResourcesForLevelAsync` is in progress, your `CreateResources` handler should cancel that task.
4. If Win2D raises `CreateResources` to recover from a lost device after you have finished loading data using `LoadResourcesForLevelAsync`, your `CreateResources` handler must reload that custom data as well as its usual global resources.

Using a `CreateResources` handler called `CanvasControl_CreateResources`, and the `LoadResourcesForLevelAsync` method shown above, here is a complete implementation that handles all four requirements:

C#

```
int? currentLevel, wantedLevel;

// This implements requirement #1.
Task levelLoadTask;

public void LoadNewLevel(int newLevel)
{
    Debug.Assert(levelLoadTask == null);
    wantedLevel = newLevel;
    levelLoadTask = LoadResourcesForLevelAsync(canvasControl, newLevel);
}

void CanvasControl_CreateResources(CanvasControl sender,
                                   CanvasCreateResourcesEventArgs args)
{
    // Synchronous resource creation, for globally-required resources goes
here:
    x = new CanvasRenderTarget(sender, ...);
    y = new CanvasRadialGradientBrush(sender, ...);
    // etc.

    args.TrackAsyncAction(CreateResourcesAsync(sender).AsAsyncAction());
```

```
 }

 async Task CreateResourcesAsync(CanvasControl sender)
 {
     // If there is a previous load in progress, stop it, and
     // swallow any stale errors. This implements requirement #3.
     if (levelLoadTask != null)
     {
         levelLoadTask.AsAsyncAction().Cancel();
         try { await levelLoadTask; } catch { }
         levelLoadTask = null;
     }

     // Unload resources used by the previous level here.

     // Asynchronous resource loading, for globally-required resources goes
here:
     baz = await CanvasBitmap.LoadAsync(sender, ...);
     qux = await CanvasBitmap.LoadAsync(sender, ...);
     // etc.

     // If we are already in a level, reload its per-level resources.
     // This implements requirement #4.
     if (wantedLevel.HasValue)
     {
        LoadNewLevel(wantedLevel.Value);
     }
 }

// Because of how this is designed to throw an exception, this must only
// ever be called from a Win2D event handler.
bool IsLoadInProgress()
{
    // No loading task?
    if (levelLoadTask == null)
        return false;

    // Loading task is still running?
    if (!levelLoadTask.IsCompleted)
        return true;

     // Query the load task results and re-throw any exceptions
     // so Win2D can see them. This implements requirement #2.
     try
     {
         levelLoadTask.Wait();
     }
     catch (AggregateException aggregateException)
     {
         // .NET async tasks wrap all errors in an AggregateException.
         // We unpack this so Win2D can directly see any lost device errors.
         aggregateException.Handle(exception => { throw exception; });
     }
     finally
     {
```

```
            levelLoadTask = null;
        }

        currentLevel = wantedLevel;
        return false;
    }

    void CanvasControl_Draw(CanvasControl sender, CanvasDrawEventArgs args)
    {
        if (IsLoadInProgress())
        {
            DrawLoadingScreen();
        }
        else
        {
            DrawCurrentLevel(currentLevel);
        }
    }
```

Resource loading and CanvasAnimatedControl

Much of the above information for `CanvasControl` generalizes to `CanvasAnimatedControl`.

However, `CanvasAnimatedControl` has a game loop thread, which should be taken into consideration while deciding how an app should load its resources.

In particular:

- Apps should avoid blocking or waiting from within the `Draw` or `Update` handlers.
- Apps may need to synchronize data which is accessed between multiple threads.

We can adjust the above implementation to be compatible with `CanvasAnimatedControl`. In particular, we should ensure that the code checking "is the level loaded" will poll instead of wait, and no `CanvasAnimatedControl` event handlers should be marked as async.

C#

```
async Task LoadResourcesForLevelAsync(ICanvasAnimatedControl
resourceCreator, int level)
{
    return
GameLoopSynchronizationContext.RunOnGameLoopThreadAsync(resourceCreator,
async() =>
    {
        levelBackground = await CanvasBitmap.LoadAsync(resourceCreator,
```

```
...);
        levelThingie = await CanvasBitmap.LoadAsync(resourceCreator, ...);
        // etc.
    }
}

// Shared state between all threads, and a lock to control access to it.
bool needToLoad;
int? currentLevel, wantedLevel;
Task levelLoadTask; // This implements requirement #1.

Object lockable = new Object();

void LoadNewLevel(int level)
{
    lock(lockable)
    {
        wantedLevel = level;
        needToLoad = true;
    }
}

void canvasAnimatedControl_CreateResources(ICanvasAnimatedControl sender,
                                    CanvasCreateResourcesEventArgs args)
{
     // Synchronous resource creation, for globally-required resources goes
here:
     x = new CanvasRenderTarget(sender, ...);
     y = new CanvasRadialGradientBrush(sender, ...);
     // etc.

     args.TrackAsyncAction(CreateResourcesAsync(sender).AsAsyncAction());
}

async Task CreateResourcesAsync(CanvasAnimatedControl sender)
{
    // If there is a previous load in progress, stop it, and
    // swallow any stale errors. This implements requirement #3.
    lock(lockable)
    {
        if (levelLoadTask != null)
        {
            levelLoadTask.AsAsyncAction().Cancel();
            try { await levelLoadTask; } catch { }
            levelLoadTask = null;
        }
    }

    // Unload resources used by the previous level here.

    // Asynchronous resource loading, for globally-required resources goes
here:
    baz = await CanvasBitmap.LoadAsync(sender, ...);
    qux = await CanvasBitmap.LoadAsync(sender, ...);
```

```
    // etc.

    // If we are already in a level, reload its per-level resources.
    // This implements requirement #4.
    int? levelThatNeedsReloading;
    lock(lockable)
    {
        levelThatNeedsReloading = wantedLevel;
    }
    if (levelThatNeedsReloading.HasValue)
    {
        LoadNewLevel(wantedLevel.Value);
    }
}

void canvasAnimatedControl_Update(ICanvasAnimatedControl sender,
CanvasAnimatedUpdateEventArgs args)
{
    lock(lockable)
    {
        // Check if there is already an outstanding level-loading Task.
        // If so, don't try to spin up a new one.
        bool beginLoad = levelLoadTask == null && needToLoad;
        needToLoad = false;

        if (beginLoad)
        {
            levelLoadTask = LoadResourcesForLevelAsync(sender, wantedLevel);
        }

        // Indicates the loading task was run and just finished.
        if(levelLoadTask != null && levelLoadTask.IsCompleted)
        {
            AggregateException levelLoadException = levelLoadTask.Exception;
            levelLoadTask = null;

            // Query the load task results and re-throw any exceptions
            // so Win2D can see them. This implements requirement #2.
            if(levelLoadException != null)
            {
                // .NET async tasks wrap all errors in an
AggregateException.
                // We unpack this so Win2D can directly see any lost device
errors.
                levelLoadException.Handle(exception => { throw exception;
});
            }

            currentLevel = wantedLevel;
        }
    }
}

bool IsLoadInProgress()
{
```

```
    lock(lockable)
    {
        return levelLoadTask != null;
    }
}

void canvasAnimatedControl_Draw(ICanvasAnimatedControl sender,
CanvasAnimatedDrawEventArgs args)
{
    if (IsLoadInProgress())
    {
        DrawLoadingScreen(args.DrawingSession);
    }
    else
    {
        DrawCurrentLevel(args.DrawingSession, currentLevel);
    }
}
```

It's worth pointing out that there are special implications of using `await` from within application code which runs on the game loop thread. For example, when a task is run using `RunOnGameLoopThreadAsync` and contains an `await`, the first await may result in `RunOnGameLoopThreadAsync` finishing. The remainder of the task is scheduled according a continuation handler. And by default, this continuation handler is chosen from the application's thread pool, according to the default .NET `SynchronizationContext`. The remainder of the task might not run on the game loop thread at all.

To remedy this, and schedule work using `RunOnGameLoopThreadAsync` which contains `await` where the work must all be run on the game loop thread, see the `GameLoopSynchronizationContext` sample.

Avoiding memory leaks

Article • 05/29/2023

When using Win2D controls in managed XAML applications, care must be taken to avoid reference count cycles that could prevent these controls ever being reclaimed by the garbage collector.

You have a problem if...

- You are using Win2D from a .NET language such as C# (not native C++)
- You use one of the Win2D XAML controls:
  - CanvasControl
  - CanvasVirtualControl
  - CanvasAnimatedControl
  - CanvasSwapChainPanel
- You subscribe to events of the Win2D control (eg. `Draw`, `CreateResources`, `SizeChanged`...)
- Your app moves back and forth between more than one XAML page

If all these conditions are met, a reference count cycle will keep the Win2D control from ever being garbage collected. New Win2D resources are allocated each time the app moves to a different page, but the old ones are never freed so memory is leaked. To avoid this, you must add code to explicitly break the cycle.

How to fix it

To break the reference count cycle and let your page be garbage collected:

- Hook the `Unloaded` event of the XAML page which contains the Win2D control
- In the `Unloaded` handler, call `RemoveFromVisualTree` on the Win2D control
- In the `Unloaded` handler, release (by setting to `null`) any explicit references to the Win2D control

Example code:

C#

```
void page_Unloaded(object sender, RoutedEventArgs e)
{
    this.canvas.RemoveFromVisualTree();
```

```
    this.canvas = null;
}
```

For working examples, see any of the Example Gallery demo pages.

How to test for cycle leaks

To test whether your application is correctly breaking refcount cycles, add a finalizer method to any XAML pages which contain Win2D controls:

C#

```
~MyPage()
{
    System.Diagnostics.Debug.WriteLine("~" + GetType().Name);
}
```

In your `App` constructor, set up a timer that will make sure garbage collection occurs at regular intervals:

C#

```
var gcTimer = new DispatcherTimer();
gcTimer.Tick += (sender, e) => { GC.Collect(); };
gcTimer.Interval = TimeSpan.FromSeconds(1);
gcTimer.Start();
```

Navigate to the page, then away from it to some other page. If all cycles have been broken, you will see `Debug.WriteLine` output in the Visual Studio output pane within a second or two.

Note that calling `GC.Collect` is disruptive and hurts performance, so you should remove this test code as soon as you finish testing for leaks!

The gory details

A cycle occurs when an object A has a reference to B, at the same time as B also has a reference to A. Or when A references B, and B references C, while C references A, etc.

When subscribing to events of a XAML control, this sort of cycle is pretty much inevitable:

- XAML page holds references to all the controls contained within it

- Controls hold references to the handler delegates that have been subscribed to their events
- Each delegate holds a reference to its target instance
- Event handlers are typically instance methods of the XAML page class, so their target instance references point back to the XAML page, creating a cycle

If all the objects involved are implemented in .NET, such cycles are not a problem because .NET is garbage collected, and the garbage collection algorithm is able to identify and reclaim groups of objects even if they are linked in a cycle.

Unlike .NET, C++ manages memory by reference counting, which is unable to detect and reclaim cycles of objects. In spite of this limitation, C++ apps using Win2D have no problem because C++ event handlers default to holding weak rather than strong references to their target instance. Therefore the page references the control, and the control references the event handler delegate, but this delegate does not reference back to the page so there is no cycle.

The problem comes when a C++ WinRT component such as Win2D is used by a .NET application:

- The XAML page is part of the application, so uses garbage collection
- The Win2D control is implemented in C++, so uses reference counting
- The event handler delegate is part of the application, so uses garbage collection and holds a strong reference to its target instance

A cycle is present, but the Win2D objects participating in this cycle are not using .NET garbage collection. This means the garbage collector is unable to see the entire chain, so it cannot detect or reclaim the objects. When this occurs, the application must help out by explicitly breaking the cycle. This can be done either by releasing all references from the page to the control (as recommended above) or by releasing all references from the control to event handler delegates that might point back to the page (using the page Unloaded event to unsubscribe all event handlers).

Implementing custom effects

Article • 05/30/2023

Win2D provides several APIs to represent objects that can be drawn, which are divided into two categories: images and effects. Images, represented by the `ICanvasImage` interface, have no inputs and can be directly drawn on a given surface. For example, `CanvasBitmap`, `VirtualizedCanvasBitmap` and `CanvasRenderTarget` are examples of image types. Effects, on the other hand, are represented by the `ICanvasEffect` interface. They can have inputs as well as additional resources, and can apply arbitrary logic to produce their outputs (as an effect is also an image). Win2D includes effects wrapping most D2D effects, such as `GaussianBlurEffect`, `TintEffect` and `LuminanceToAlphaEffect`.

Images and effects can also be chained together, to create arbitrary graphs which can then be displayed in your application (also refer to the D2D docs on Direct2D effects). Together, they provide an extremely flexible system to author complex graphics in an efficient manner. However, there are cases where the built-in effects are not sufficient, and you might want to build your very own Win2D effect. To support this, Win2D includes a set of powerful interop APIs that allows defining custom images and effects that can seamlessly integrate with Win2D.

> If you are using C# and want to implement a custom effect or effect graph, it is recommended to use **ComputeSharp** rather than trying to implement an effect from scratch. **See the paragraph below** for a detailed explanation of how to use this library to implement custom effects that integrate seamlessly with Win2D.

> **Platform APIs:** ICanvasImage, CanvasBitmap, VirtualizedCanvasBitmap, CanvasRenderTarget, CanvasEffect, GaussianBlurEffect, TintEffect, ICanvasLuminanceToAlphaEffectImage, IGraphicsEffectSource, ID2D21Image, ID2D1Factory1, ID2D1Effect

Implementing a custom `ICanvasImage`

The simplest scenario to support is creating a custom `ICanvasImage`. As we mentioned, this is the WinRT interface defined by Win2D which represents all kinds of images that Win2D can interop with. This interface only exposes two `GetBounds` methods, and extends `IGraphicsEffectSource`, which is a marker interface representing "some effect source".

As you can see, there are no "functional" APIs exposed by this interface to actually perform any drawing. In order to implement your own `ICanvasImage` object, you'll need to also implement the `ICanvasImageInterop` interface, which exposes all the necessary logic for Win2D to draw the image. This is a COM interface defined in the public `Microsoft.Graphics.Canvas.native.h` header, that ships with Win2D.

The interface is defined as follows:

C++

```
[uuid("E042D1F7-F9AD-4479-A713-67627EA31863")]
class ICanvasImageInterop : IUnknown
{
    HRESULT GetDevice(
        ICanvasDevice** device,
        WIN2D_GET_DEVICE_ASSOCIATION_TYPE* type);

    HRESULT GetD2DImage(
        ICanvasDevice* device,
        ID2D1DeviceContext* deviceContext,
        WIN2D_GET_D2D_IMAGE_FLAGS flags,
        float targetDpi,
        float* realizeDpi,
        ID2D1Image** ppImage);
}
```

And it also relies on these two enumeration types, from the same header:

C++

```
enum WIN2D_GET_DEVICE_ASSOCIATION_TYPE
{
    WIN2D_GET_DEVICE_ASSOCIATION_TYPE_UNSPECIFIED,
    WIN2D_GET_DEVICE_ASSOCIATION_TYPE_REALIZATION_DEVICE,
    WIN2D_GET_DEVICE_ASSOCIATION_TYPE_CREATION_DEVICE
}

enum WIN2D_GET_D2D_IMAGE_FLAGS
{
    WIN2D_GET_D2D_IMAGE_FLAGS_NONE,
    WIN2D_GET_D2D_IMAGE_FLAGS_READ_DPI_FROM_DEVICE_CONTEXT,
    WIN2D_GET_D2D_IMAGE_FLAGS_ALWAYS_INSERT_DPI_COMPENSATION,
    WIN2D_GET_D2D_IMAGE_FLAGS_NEVER_INSERT_DPI_COMPENSATION,
    WIN2D_GET_D2D_IMAGE_FLAGS_MINIMAL_REALIZATION,
    WIN2D_GET_D2D_IMAGE_FLAGS_ALLOW_NULL_EFFECT_INPUTS,
    WIN2D_GET_D2D_IMAGE_FLAGS_UNREALIZE_ON_FAILURE
}
```

The two `GetDevice` and `GetD2DImage` methods are all that's needed to implement custom images (or effects), as they provide Win2D with the extensibility points to initialize them on a given device and retrieve the underlying D2D image to draw. Implementing these methods correctly is critical to ensure things will work properly in all supported scenarios.

Let's go over them to see how each method works.

Implementing `GetDevice`

The `GetDevice` method is the simplest of the two. What it does is it retrieves the canvas device associated with the effect, so that Win2D can inspect it if necessary (for instance, to ensure it matches the device in use). The `type` parameter indicates the "association type" for the returned device.

There are two main possible cases:

- If the image is an effect, it should support being "realized" and "unrealized" on multiple devices. What this means is: a given effect is created in an uninitialized state, then it can be realized when a device is passed while drawing, and after that it can keep being used with that device, or it can be moved to a different device. In that case, the effect will reset its internal state and then realize itself again on the new device. This means that the associated canvas device can change over time, and it can also be `null`. Because of this, `type` should be set to `WIN2D_GET_DEVICE_ASSOCIATION_TYPE_REALIZATION_DEVICE`, and the returned device should be set to the current realization device, if one is available.
- Some images have a single "owning device" which is assigned at creation time and can never change. For instance, this would be the case for an image representing a texture, as that is allocated on a specific device and cannot be moved. When `GetDevice` is called, it should return the creation device and set `type` to `WIN2D_GET_DEVICE_ASSOCIATION_TYPE_CREATION_DEVICE`. Note that when this type is specified, the returned device should not be `null`.

> ⓘ **Note**
>
> Win2D can call `GetDevice` while recursively traversing an effect graph, meaning there might be multiple active calls to `GetD2DImage` in the stack. Because of this, `GetDevice` should not take a blocking lock on the current image, as that could potentially deadlock. Rather, it should use a re-entrant lock in a non-blocking manner, and return an error if it cannot be acquired. This ensures that the same

thread recursively calling it will successfully acquire it, whereas concurrent threads doing the same will fail gracefully.

Implementing `GetD2DImage`

`GetD2DImage` is where most of the work takes place. This method is responsible for retrieving the `ID2D1Image` object that Win2D can draw, optionally realizing the current effect if needed. This also includes recursively traversing and realizing the effect graph for all sources, if any, as well as initializing any state that the image might need (eg. constant buffers and other properties, resource textures, etc.).

The exact implementation of this method is highly dependent on the image type and it can vary a lot, but generally speaking for an arbitrary effect you can expect the method to perform the following steps:

- Check whether the call was recursive on the same instance, and fail if so. This is needed to detect cycles in an effect graph (eg. effect `A` has effect `B` as source, and effect `B` has effect `A` as source).
- Acquire a lock on the image instance to protect against concurrent access.
- Handle the target DPIs according to the input flags
- Validate whether the input device matches the one in use, if any. If it does not match and the current effect supports realization, unrealize the effect.
- Realize the effect on the input device. This can include registering the D2D effect on the `ID2D1Factory1` object retrieved from the input device or device context, if needed. Additionally, all necessary state should be set on the D2D effect instance being created.
- Recursively traverse any sources and bind them to the D2D effect.

With respect to the input flags, there are several possible cases that custom effects should properly handle, to ensure compatibility with all other Win2D effects. Excluding `WIN2D_GET_D2D_IMAGE_FLAGS_NONE`, the flags to handle are the following:

- `WIN2D_GET_D2D_IMAGE_FLAGS_READ_DPI_FROM_DEVICE_CONTEXT`: in this case, `device` is guaranteed to not be `null`. The effect should check whether the device context target is an `ID2D1CommandList`, and if so, add the `WIN2D_GET_D2D_IMAGE_FLAGS_ALWAYS_INSERT_DPI_COMPENSATION` flag. Otherwise, it should set `targetDpi` (which is also guaranteed to not be `null`) to the DPIs retrieved from the input context. Then, it should remove `WIN2D_GET_D2D_IMAGE_FLAGS_READ_DPI_FROM_DEVICE_CONTEXT` from the flags.

- `WIN2D_GET_D2D_IMAGE_FLAGS_ALWAYS_INSERT_DPI_COMPENSATION` and `WIN2D_GET_D2D_IMAGE_FLAGS_NEVER_INSERT_DPI_COMPENSATION`: used when setting effect sources (see notes below).
- `WIN2D_GET_D2D_IMAGE_FLAGS_MINIMAL_REALIZATION`: if set, skips recursively realizing the sources of the effect, and just returns the realized effect with no other changes.
- `WIN2D_GET_D2D_IMAGE_FLAGS_ALLOW_NULL_EFFECT_INPUTS`: if set, effect sources being realized are allowed to be `null`, if the user has not set them to an existing source yet.
- `WIN2D_GET_D2D_IMAGE_FLAGS_UNREALIZE_ON_FAILURE`: if set, and an effect source being set is not valid, the effect should unrealize before failing. That is, if the error occurred while resolving the effect sources after realizing the effect, the effect should unrealize itself before returning the error to the caller.

With respect to the DPI-related flags, these control how effect sources are set. To ensure compatibility with Win2D, effects should automatically add DPI compensation effects to their inputs when needed. They can control whether that is the case like so:

- If `WIN2D_GET_D2D_IMAGE_FLAGS_MINIMAL_REALIZATION` is set, a DPI compensation effect is needed whenever the `inputDpi` parameter is not `0`.
- Otherwise, DPI compensation is needed if `inputDpi` is not `0`, `WIN2D_GET_D2D_IMAGE_FLAGS_NEVER_INSERT_DPI_COMPENSATION` is not set, and either `WIN2D_GET_D2D_IMAGE_FLAGS_ALWAYS_INSERT_DPI_COMPENSATION` is set, or the input DPI and the target DPI values don't match.

This logic should be applied whenever a source is being realized and bound to an input of the current effect. Note that if a DPI compensation effect is added, that should be the input set to the underlying D2D image. But, if the user tries to retrieve the WinRT wrapper for that source, the effect should take care to detect whether a DPI effect was used, and return a wrapper for the original source object instead. That is, DPI compensation effects should be transparent to users of the effect.

After all initialization logic is done, the resulting `ID2D1Image` (just like with Win2D objects, a D2D effect is also an image) should be ready to be drawn by Win2D on the target context, which is not yet known by the callee at this time.

> ⓘ **Note**
>
> Correctly implementing this method (and `ICanvasImageInterop` in general) is **extremely** complicated, and it's only meant to be done by advanced users that absolutely need the extra flexibility. A solid understanding of D2D, Win2D, COM, WinRT and C++ is recommended before attempting to write an

`ICanvasImageInterop` implementation. If your custom Win2D effect also has to wrap a custom D2D effect, you'll need to implement your own `ID2D1Effect` object as well (refer to the D2D docs on custom effects for more info on this). These docs are not an exhaustive description of all necessary logic (for instance, they don't cover how effect sources should be marshalled and managed across the D2D/Win2D boundary), so it is recommended to also use the `CanvasEffect` implementation in Win2D's codebase as a reference point for a custom effect, and modify it as needed.

Implementing `GetBounds`

The last missing component to fully implement a custom `ICanvasImage` effect is to support the two `GetBounds` overloads. To make this easy, Win2D exposes a C export which can be used to leverage the existing logic for this from Win2D on any custom image. The export is as follows:

C++

```
HRESULT GetBoundsForICanvasImageInterop(
    ICanvasResourceCreator* resourceCreator,
    ICanvasImageInterop* image,
    Numerics::Matrix3x2 const* transform,
    Rect* rect);
```

Custom images can invoke this API and pass themselves as the `image` parameter, and then simply return the result to their callers. The `transform` parameter can be `null`, if no transform is available.

Optimizing device context accesses

The `deviceContext` parameter in `ICanvasImageInterop::GetD2DImage` can sometimes be `null`, if a context is not immediately available before the invocation. This is done on purpose, so that a context is only created lazily when it's actually needed. That is, if a context is available, Win2D will pass it to the `GetD2DImage` invocation, otherwise it will let callees retrieve one on their own if necessary.

Creating a device context is relatively expensive, so to make retrieving one faster Win2D exposes APIs to access its internal device context pool. This allows custom effects to rent and return device contexts associated with a given canvas device in an efficient manner.

The device context lease APIs are defined as follows:

C++

```
[uuid("A0928F38-F7D5-44DD-A5C9-E23D94734BBB")]
interface ID2D1DeviceContextLease : IUnknown
{
    HRESULT GetD2DDeviceContext(ID2D1DeviceContext** deviceContext);
}

[uuid("454A82A1-F024-40DB-BD5B-8F527FD58AD0")]
interface ID2D1DeviceContextPool : IUnknown
{
    HRESULT GetDeviceContextLease(ID2D1DeviceContextLease** lease);
}
```

The `ID2D1DeviceContextPool` interface is implemented by `CanvasDevice`, which is the Win2D type implementing the `ICanvasDevice` interface. To use the pool, use `QueryInterface` on the device interface to obtain an `ID2D1DeviceContextPool` reference, and then call `ID2D1DeviceContextPool::GetDeviceContextLease` to obtain an `ID2D1DeviceContextLease` object to access the device context. Once that's no longer needed, release the lease. Make sure to not touch the device context after the lease has been released, as it might be used concurrently by other threads.

Enabling WinRT wrappers lookup

As seen in the Win2D interop docs, the Win2D public header also exposes a `GetOrCreate` method (accessible from the `ICanvasFactoryNative` activation factory, or through the `GetOrCreate` C++/CX helpers defined in the same header). This allows retrieving a WinRT wrapper from a given native resource. For instance, it lets you retrieve or create a `CanvasDevice` instance from an `ID2D1Device1` object, a `CanvasBitmap` from an `ID2D1Bitmap`, etc.

This method also works for all built-in Win2D effects: retrieving the native resource for a given effect and then using that to retrieve the corresponding Win2D wrapper will correctly return the owning Win2D effect for it. In order for custom effects to also benefit from the same mapping system, Win2D exposes several APIs in the interop interface for the activation factory for `CanvasDevice`, which is the `ICanvasFactoryNative` type, as well as an additional effect factory interface, `ICanvasEffectFactoryNative`:

C++

```
[uuid("29BA1A1F-1CFE-44C3-984D-426D61B51427")]
class ICanvasEffectFactoryNative : IUnknown
{
    HRESULT CreateWrapper(
```

```
        ICanvasDevice* device,
        ID2D1Effect* resource,
        float dpi,
        IInspectable** wrapper);
};

[uuid("695C440D-04B3-4EDD-BFD9-63E51E9F7202")]
class ICanvasFactoryNative : IInspectable
{
    HRESULT GetOrCreate(
        ICanvasDevice* device,
        IUnknown* resource,
        float dpi,
        IInspectable** wrapper);

    HRESULT RegisterWrapper(IUnknown* resource, IInspectable* wrapper);

    HRESULT UnregisterWrapper(IUnknown* resource);

    HRESULT RegisterEffectFactory(
        REFIID effectId,
        ICanvasEffectFactoryNative* factory);

    HRESULT UnregisterEffectFactory(REFIID effectId);
};
```

There are several APIs to consider here, as they're needed to support all the various scenarios where Win2D effects can be used, as well as how developers could do interop with the D2D layer and then try to resolve wrappers for them. Let's go over each of these APIs.

The `RegisterWrapper` and `UnregisterWrapper` methods are meant to be invoked by custom effects to add themselves into the internal Win2D cache:

- `RegisterWrapper`: registers a native resource and its owning WinRT wrapper. The `wrapper` parameter is required to also implemement IWeakReferenceSource, so that it can be cached correctly without causing reference cycles which would lead to memory leaks. The method returns `S_OK` if the native resource could be added to the cache, `S_FALSE` if there was already a registered wrapper for `resource`, and an error code if an error occurs.
- `UnregisterWrapper`: unregisters a native resource and its wrapper. Returns `S_OK` if the resource could be removed, `S_FALSE` if `resource` was not already registered, and an erro code if another error occurrs.

Custom effects should call `RegisterWrapper` and `UnregisterWrapper` whenever they are realized and unrealized, ie. when a new native resource is created and associated with them. Custom effects that do not support realization (eg. those having a fixed

associated device) can call `RegisterWrapper` and `UnregisterWrapper` when they are created and destroyed. Custom effects should make sure to correctly unregister themselves from all possible code paths that would cause the wrapper to become invalid (eg. including when the object is finalized, in case it's implemented in a managed language).

The `RegisterEffectFactory` and `UnregisterEffectFactory` methods are also meant to be used by custom effects, so that they can also register a callback to create a new wrapper in case a developer tries to resolve one for an "orphaned" D2D resource:

- `RegisterEffectFactory`: register a callback that takes in input the same parameters that a developer passed to `GetOrCreate`, and creates a new inspectable wrapper for the input effect. The effect id is used as key, so that each custom effect can register a factory for it when it's first loaded. Of course, this should only be done once per effect type, and not every time the effect is realized. The `device`, `resource` and `wrapper` parameters are checked by Win2D before invoking any registered callback, so they are guaranteed to not be `null` when `CreateWrapper` is invoked. The `dpi` is considered optional, and can be ignored in case the effect type doesn't have a specific use for it. Note that when a new wrapper is created from a registered factory, that factory should also make sure that the new wrapper is registered in the cache (Win2D will not automatically add wrappers produced by external factories to the cache).
- `UnregisterEffectFactory`: removes a previously register callback. For instance, this could be used if an effect wrapper is implemented in a managed assembly which is being unloaded.

> ⓘ **Note**
>
> `ICanvasFactoryNative` is implemented by the activation factory for `CanvasDevice`, which you can retrieve by either manually calling RoGetActivationFactory, or using helper APIs from the language extensions you're using (eg. winrt::get_activation_factory in C++/WinRT). For more info, see WinRT type system for more information on how this works.

For a practical example of where this mapping comes into play, consider how built-in Win2D effects work. If they are not realized, all state (eg. properties, sources, etc.) is stored in an internal cache in each effect instance. When they are realized, all state is transferred to the native resource (eg. properties are set on the D2D effect, all sources are resolved and mapped to effect inputs, etc.), and as long as the effect is realized it will act as the authority on the state of the wrapper. That is, if the value of any property

is fetched from the wrapper, it will retrieve the updated value for it from the native D2D resource associated with it.

This ensures that if any changes are made directly to the D2D resource, those will be visible on the outer wrapper as well, and the two will never be "out of sync". When the effect is unrealized, all state is transferred back from the native resource to the wrapper state, before the resource is released. It will be kept and updated there until the next time the effect is realized. Now, consider this sequence of events:

- You have some Win2D effect (either built-in, or custom).
- You get the `ID2D1Image` from it (which is an `ID2D1Effect`).
- You create an instance of a custom effect.
- You also get the `ID2D1Image` from that.
- You manually set this image as input for the previous effect (via ID2D1Effect::SetInput).
- You then ask that first effect for the WinRT wrapper for that input.

Since the effect is realized (it was realized when the native resource was requested), it will use the native resource as the source of truth. As such, it will get the `ID2D1Image` corresponding to the requested source, and try to retrieve the WinRT wrapper for it. If the effect this input was retrieved from has correctly added its own pair of native resource and WinRT wrapper to Win2D's cache, the wrapper will be resolved and returned to callers. If not, that property access will fail, as Win2D can't resolve WinRT wrappers for effects it does not own, as it doesn't know how to instantiate them.

This is where `RegisterWrapper` and `UnregisterWrapper` help, as they allow custom effects to seamlessly participate in Win2D's wrapper resolution logic, so that the correct wrapper can always be retrieved for any effect source, regardless of whether it was set from WinRT APIs, or directly from the underlying D2D layer.

To explain how the effect factories also come into play, consider this scenario:

- A user creates an instance of a custom wrapper and realizes it
- They then gets a reference to the underlying D2D effect and keeps it.
- Then, the effect is realized on a different device. The effect will unrealize and re-realize, and in doing so it will create a new D2D effect. The previous D2D effect no longer as an associated inspectable wrapper at this point.
- The user then calls `GetOrCreate` on the first D2D effect.

Without a callback, Win2D would just fail to resolve a wrapper, as there's no registered wrapper for it. If a factory is registered instead, a new wrapper for that D2D effect can be created and returned, so the scenario just keeps working seamlessly for the user.

Implementing a custom `ICanvasEffect`

The Win2D `ICanvasEffect` interface extends `ICanvasImage`, so all the previous points apply to custom effects as well. The only difference is the fact that `ICanvasEffect` also implements additional methods specific to effects, such as invalidating a source rectangle, getting the required rectangles and so on.

To support this, Win2D exposes C exports that authors of custom effects can use, so that they won't have to reimplement all this extra logic from scratch. This works in the same way as the C export for `GetBounds`. Here are the available exports for effects:

C++

```
HRESULT InvalidateSourceRectangleForICanvasImageInterop(
    ICanvasResourceCreatorWithDpi* resourceCreator,
    ICanvasImageInterop* image,
    uint32_t sourceIndex,
    Rect const* invalidRectangle);

HRESULT GetInvalidRectanglesForICanvasImageInterop(
    ICanvasResourceCreatorWithDpi* resourceCreator,
    ICanvasImageInterop* image,
    uint32_t* valueCount,
    Rect** valueElements);

HRESULT GetRequiredSourceRectanglesForICanvasImageInterop(
    ICanvasResourceCreatorWithDpi* resourceCreator,
    ICanvasImageInterop* image,
    Rect const* outputRectangle,
    uint32_t sourceEffectCount,
    ICanvasEffect* const* sourceEffects,
    uint32_t sourceIndexCount,
    uint32_t const* sourceIndices,
    uint32_t sourceBoundsCount,
    Rect const* sourceBounds,
    uint32_t valueCount,
    Rect* valueElements);
```

Let's go over how they can be used:

- `InvalidateSourceRectangleForICanvasImageInterop` is meant to support `InvalidateSourceRectangle`. Simply marshal the input parameters and invoke it directly, and it'll take care of all the necessary work. Note that the `image` parameter is the current effect instance being implemented.
- `GetInvalidRectanglesForICanvasImageInterop` supports `GetInvalidRectangles`. This also requires no special consideration, other than needing to dispose the returned COM array once it's no longer needed.

- `GetRequiredSourceRectanglesForICanvasImageInterop` is a shared method that can support both `GetRequiredSourceRectangle` and `GetRequiredSourceRectangles`. That is, it takes a pointer to an existing array of values to populate, so callers can either pass a pointer to a single value (which can also be on the stack, to avoid one allocation), or to an array of values. The implementation is the same in both cases, so a single C export is enough to power both of them.

Custom effects in C# using ComputeSharp

As we mentioned, if you're using C# and want to implement a custom effect, the recommended approach is to use the ComputeSharp library. It enables you to both implement custom D2D1 pixel shaders entirely in C#, as well as to easily define custom effects graphs that are compatible with Win2D. The same library is also used in the Microsoft Store to power several graphics components in the application.

You can add a reference to ComputeSharp in your project through NuGet:

- On UWP, select the **ComputeSharp.D2D1.Uwp** package.
- On WinAppSDK, select the **ComputeSharp.D2D1.WinUI** package.

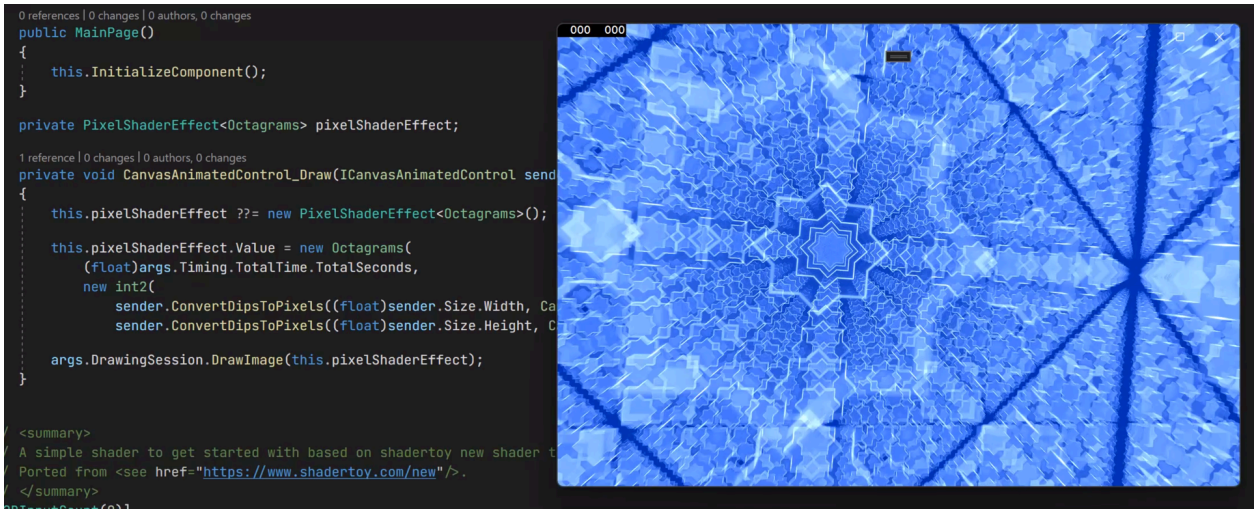
> **Note**
>
> Many APIs in ComputeSharp.D2D1.* are identical across the UWP and WinAppSDK targets, the only difference being the namespace (ending in either `.Uwp` or `.WinUI`). However, the UWP target is in sustained maintenance and not receiving new features. As such, some code changes might be needed compared to the samples shown here for WinUI. The snippets in this document reflect the API surface as of ComputeSharp.D2D1.WinUI 3.0.0 (the last release for the UWP target is instead 2.1.0).

There are two main components in ComputeSharp to interop with Win2D:

- `PixelShaderEffect<T>`: a Win2D effect that is powered by a D2D1 pixel shader. The shader itself is written in C# using the APIs provided by ComputeSharp. This class also provides properties to set effect sources, constant values, and more.
- `CanvasEffect`: a base class for custom Win2D effects that wraps an arbitrary effect graph. It can be used to "package" complex effects into an easy to use object that can be reused in several parts of an application.

Here is an example of a custom pixel shader (ported from this shadertoy shader), used with `PixelShaderEffect<T>` and then draw onto a Win2D `CanvasControl` (note that

`PixelShaderEffect<T>` implements `ICanvasImage`):



You can see how in just two lines of code you can create an effect and draw it via Win2D. ComputeSharp takes care of all the work necessary to compile the shader, register it, and manage the complex lifetime of a Win2D-compatible effect.

Next, let's see a step by step guide on how to create a custom Win2D effect that also uses a custom D2D1 pixel shader. We'll go over how to author a shader with ComputeSharp and setup its properties, and then how to create a custom effect graph packaged into a `CanvasEffect` type that can easily be reused in your application.

Designing the effect

For this demo, we want to create a simple frosted glass effect.

This will include the following components:

- Gaussian blur
- Tint effect
- Noise (which we can procedurally generate with a shader)

We'll also want to expose properties to control the blur and noise amount. The final effect will contain a "packaged" version of this effect graph and be easy to use by just creating an instance, setting those properties, connecting a source image, and then drawing it. Let's get started!

Creating a custom D2D1 pixel shader

For the noise on top of the effect, we can use a simple D2D1 pixel shader. The shader will compute a random value based on its coordinates (which will act as a "seed" for the

random number), and then it will use that noise value to compute the RGB amount for that pixel. We can then blend this noise on top of the resulting image.

To write the shader with ComputeSharp, we just need to define a `partial struct` type implementing the `ID2D1PixelShader` interface, and then write our logic in the `Execute` method. For this noise shader, we can write something like this:

C#

```
using ComputeSharp;
using ComputeSharp.D2D1;

[D2DInputCount(0)]
[D2DRequiresScenePosition]
[D2DShaderProfile(D2D1ShaderProfile.PixelShader40)]
[D2DGeneratedPixelShaderDescriptor]
public readonly partial struct NoiseShader(float amount) : ID2D1PixelShader
{
    /// <inheritdoc/>
    public float4 Execute()
    {
        // Get the current pixel coordinate (in pixels)
        int2 position = (int2)D2D.GetScenePosition().XY;

        // Compute a random value in the [0, 1] range for each target pixel.
This line just
        // calculates a hash from the current position and maps it into the
[0, 1] range.
        // This effectively provides a "random looking" value for each
pixel.
        float hash = Hlsl.Frac(Hlsl.Sin(Hlsl.Dot(position, new float2(41,
289))) * 45758.5453f);

        // Map the random value in the [0, amount] range, to control the
strength of the noise
        float alpha = Hlsl.Lerp(0, amount, hash);

        // Return a white pixel with the random value modulating the opacity
        return new(1, 1, 1, alpha);
    }
}
```

> **Note**
>
> While the shader is written entirely in C#, basic knowledge of HLSL (the programming language for DirectX shaders, which ComputeSharp transpiles C# to) is recommended.

Let's go over this shader in detail:

- The shader has no inputs, it just produces an infinite image with random grayscale noise.
- The shader requires access to the current pixel coordinate.
- The shader is precompiled at build time (using the `PixelShader40` profile, which is guaranteed to be available on any GPU where the application could be running).
- The `[D2DGeneratedPixelShaderDescriptor]` attribute is needed to trigger the source generator bundled with ComputeSharp, which will analyze the C# code, transpile it to HLSL, compile the shader to bytecode, etc.
- The shader captures a `float amount` parameter, via its primary constructor. The source generator in ComputeSharp will automatically take care of extracting all captured values in a shader and preparing the constant buffer that D2D needs to initialize the shader state.

And this part is done! This shader will generate our custom noise texture whenever needed. Next, we need to create our packaged effect with the effect graph connecting all our effects together.

Creating a custom effect

For our easy to use, packaged effect, we can use the `CanvasEffect` type from ComputeSharp. This type provides a straightforward way to setup all the necessary logic to create an effect graph and update it via public properties that users of the effect can interact with. There are two main methods we'll need to implement:

- `BuildEffectGraph`: this method is responsible for building the effect graph that we want to draw. That is, it needs to create all effects we need, and register the output node for the graph. For effects that can be updated at a later time, the registration is done with an associated `CanvasEffectNode<T>` value, which acts as lookup key to retrieve the effects from the graph when needed.
- `ConfigureEffectGraph`: this method refreshes the effect graph by applying the settings that the user has configured. This method is automatically invoked when needed, right before drawing the effect, and only if at least one effect property has been modified since the last time the effect was used.

Our custom effect can be defined as follows:

C#

```
using ComputeSharp.D2D1.WinUI;
using Microsoft.Graphics.Canvas;
using Microsoft.Graphics.Canvas.Effects;

public sealed class FrostedGlassEffect : CanvasEffect
```

```
{
    private static readonly CanvasEffectNode<GaussianBlurEffect> BlurNode =
new();
    private static readonly CanvasEffectNode<PixelShaderEffect<NoiseShader>>
NoiseNode = new();

    private ICanvasImage? _source;
    private double _blurAmount;
    private double _noiseAmount;

    public ICanvasImage? Source
    {
        get => _source;
        set => SetAndInvalidateEffectGraph(ref _source, value);
    }

    public double BlurAmount
    {
        get => _blurAmount;
        set => SetAndInvalidateEffectGraph(ref _blurAmount, value);
    }

    public double NoiseAmount
    {
        get => _noiseAmount;
        set => SetAndInvalidateEffectGraph(ref _noiseAmount, value);
    }

    /// <inheritdoc/>
    protected override void BuildEffectGraph(CanvasEffectGraph effectGraph)
    {
        // Create the effect graph as follows:
        //
        // ┌────────┐   ┌──────┐
        // │ source ├──►│ blur ├──────┐
        // └────────┘   └──────┘      ▼
        //                         ┌─────┐   ┌────────┐
        //                         │ blend ├──►│ output │
        //                         └─────┘   └────────┘
        //                            ▲
        //    ┌───────┐               │
        //    │ noise ├───────────────┘
        //    └───────┘
        //
        GaussianBlurEffect gaussianBlurEffect = new();
        BlendEffect blendEffect = new() { Mode = BlendEffectMode.Overlay };
        PixelShaderEffect<NoiseShader> noiseEffect = new();
        PremultiplyEffect premultiplyEffect = new();

        // Connect the effect graph
        premultiplyEffect.Source = noiseEffect;
        blendEffect.Background = gaussianBlurEffect;
        blendEffect.Foreground = premultiplyEffect;

        // Register all effects. For those that need to be referenced later
(ie. the ones with
```

```
        // properties that can change), we use a node as a key, so we can
perform lookup on
        // them later. For others, we register them anonymously. This allows
the effect
        // to autommatically and correctly handle disposal for all effects
in the graph.
        effectGraph.RegisterNode(BlurNode, gaussianBlurEffect);
        effectGraph.RegisterNode(NoiseNode, noiseEffect);
        effectGraph.RegisterNode(premultiplyEffect);
        effectGraph.RegisterOutputNode(blendEffect);
    }

    /// <inheritdoc/>
    protected override void ConfigureEffectGraph(CanvasEffectGraph
effectGraph)
    {
        // Set the effect source
        effectGraph.GetNode(BlurNode).Source = Source;

        // Configure the blur amount
        effectGraph.GetNode(BlurNode).BlurAmount = (float)BlurAmount;

        // Set the constant buffer of the shader
        effectGraph.GetNode(NoiseNode).ConstantBuffer = new
NoiseShader((float)NoiseAmount);
    }
}
```

You can see there are four sections in this class:

- First, we have fields to track all mutable state, such as the effects that can be updated as well as the backing fields for all the effect properties that we want to expose to users of the effect.
- Next, we have properties to configure the effect. The setter of each property uses the `SetAndInvalidateEffectGraph` method exposed by `CanvasEffect`, which will automatically invalidate the effect if the value being set is different than the current one. This ensures the effect is only configured again when really necessary.
- Lastly, we have the `BuildEffectGraph` and `ConfigureEffectGraph` methods we mentioned above.

> ⓘ **Note**
>
> The `PremultiplyEffect` node after the noise effect is very important: this is because Win2D effects assume that the output is premultiplied, whereas pixel shaders generally work with unpremultiplied pixels. As such, remember to manually insert premultiply/unpremultiply nodes before and after custom shaders, to ensure colors are correctly preserved.

> ⓘ **Note**
>
> This sample effect is using WinUI 3 namespaces, but the same code can be used on UWP as well. In that case, the namespace for ComputeSharp will be `ComputeSharp.Uwp`, matching the package name.

Ready to draw!

And with this, our custom frosted glass effect is ready! We can easily draw it as follows:

C#

```
private void CanvasControl_Draw(CanvasControl sender, CanvasDrawEventArgs
args)
{
    FrostedGlassEffect effect = new()
    {
        Source = _canvasBitmap,
        BlurAmount = 12,
        NoiseAmount = 0.1
    };

    args.DrawingSession.DrawImage(effect);
}
```

In this example, we're drawing the effect from the `Draw` handler of a `CanvasControl`, using a `CanvasBitmap` which we previously loaded as source. This is the input image we'll use to test the effect:

And here is the result:

> ⓘ **Note**
>
> Credits to Dominic Lange for the picture.

Push notifications overview

Article • 03/16/2023

Push notifications in the Windows App SDK use Windows Push Notifications Service (WNS) to send rich notifications to Windows apps using Azure App Registration identities.

Push notification types and usage scenarios

Push notifications can be used to enable several distinct features. The content and effect of a push notification will vary based on the way it is being used.

Raw notifications

Raw notifications are consumed by the app itself and are not communicated to the user. They can be used to control application behavior or notify applications of state changes remotely.

Scenario	Description	Example
Application Wake Up	Raw notifications can be used by app developers to wake up their application instead of it constantly running, which frees up user resources.	*Without raw notifications*: The Contoso Chat app runs in the background while waiting for a VOIP call. *With raw notifications*: The Contoso app process can be in a terminated state until a raw notification signals it and brings the process up, indicating a VOIP call has been initiated.
Real Time Sync	Raw notifications can replace polling scenarios by allowing the app developer to send payloads from their App Service to the App Client on the local device. These payloads notify the App Client to sync with the App Service.	*Without raw notifications*: The Contoso Chat app polls the Contoso cloud service every 30 mins to check for content updates, and initiates a sync if updates are available. *With raw notifications*: The Contoso Chat app is notified immediately when new content is available, and syncs that content right away.

App notifications from the cloud

App notifications are used to communicate with the user. The notification content is displayed in a transient window in the bottom right corner of the screen and in the Notification Center (called Action Center in Windows 10). App notifications can be used to inform the user of application status or state changes, or to prompt the user to take an action. App notifications can be either push (sent from the cloud) or sent locally. Sending a cloud-sourced app notification is similar to sending a raw notification, except the *X-WNS-Type* header is `toast`, *Content-Type* is `text/xml`, and the content contains the app notification XML payload, which you can learn more about here.

Limitations

The push notifications support in the Windows App SDK currently has these limitations:

- If your app is published as *self-contained* or is running with the elevated (admin) privilege, this feature may not be supported. In your app, use the `winrt::PushNotificationManager::IsSupported()` check as demonstrated in Quickstart: Push notifications in the Windows App SDK and implement a custom socket if the feature is unsupported.
- Microsoft reserves the right to disable or revoke apps from using push notifications.

Quickstart: Push notifications in the Windows App SDK

Article • 05/21/2024

In this quickstart you will create a desktop Windows application that sends and receives push notifications using the Windows App SDK.

Prerequisites

- Start developing Windows apps
- Either Create a new project that uses the Windows App SDK OR Use the Windows App SDK in an existing project
- An Azure Account is required in order to use Windows App SDK push notifications.
- Read Push notifications overview

Sample app

This quickstart walks through adding push notifications support to your app. See the example code from this quickstart in context in the sample apps found on GitHub.

Sample App Code

API reference

For API reference documentation for push notifications, see Microsoft.Windows.PushNotifications Namespace.

Configure your app's identity in Azure Active Directory (AAD)

Push notifications in Windows App SDK use identities from Azure Active Directory (AAD). Azure credentials are required when requesting a WNS Channel URI and when requesting access tokens in order to send push notifications. **Note**: We do **NOT** support using Windows App SDK push notifications with Microsoft Partner Center.

Step 1: Create an AAD app registration

Login to your Azure account and create a new **AAD App Registration** resource. Select *New registration*.

Step 2: Provide a name and select a multi-tenant option

1. Provide an app name.
2. Push notifications require the multi-tenant option, so select that.
   a. For more information about tenants, see Who can sign in to your app?.
3. Select *Register*
4. Take note of your **Application (client) ID**, as this is your **Azure AppId** that you will be using during activation registration and access token request.
5. Take note of your **Directory (tenant) ID**, as this is your **Azure TenantId** that you will be using when requesting an access token.

> **Important**
>
> >
>
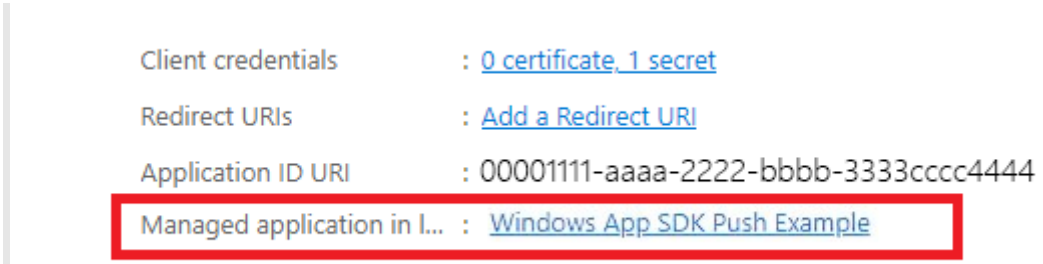
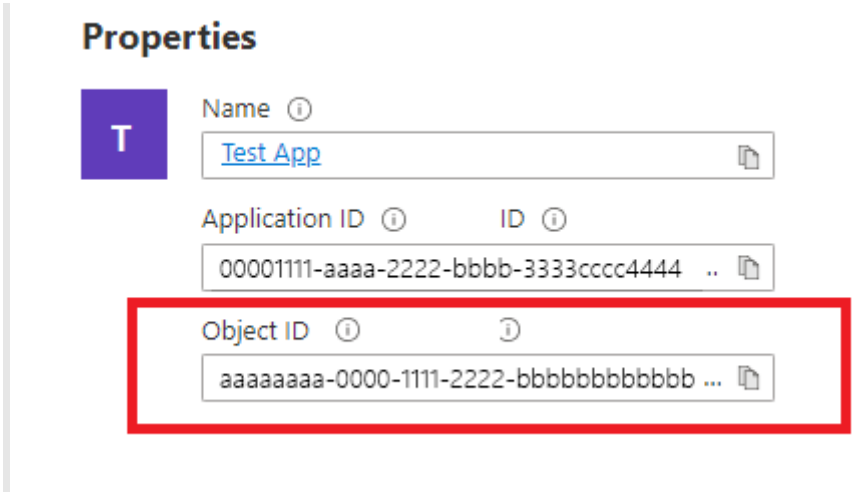
> Take note of your **Application (client) ID** and **Directory (tenant) ID**.

6. Take note of your **Object ID**, as this is your **Azure ObjectId** that you will be using when requesting a channel request. Note that this is NOT the object ID listed on the **Essentials** page. Instead, to find the correct **Object ID**, click on the app name in the **Managed application in local directory** field on the **Essentials** page:

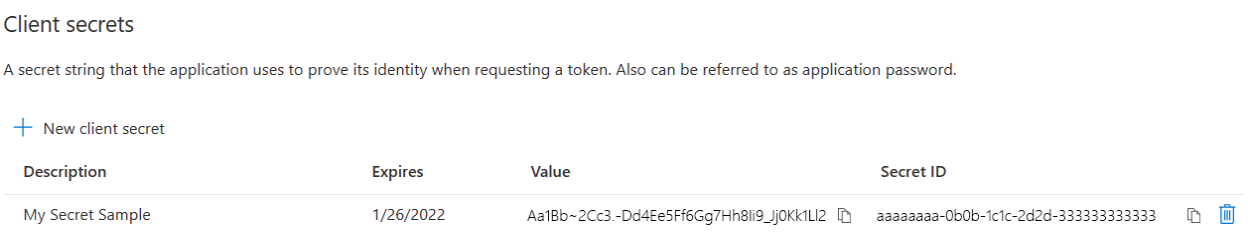




> **Note**
>
> A **service principal** is required to get an Object ID, if there is not one associated with your app, follow the steps in one of the following articles to create one in the Azure portal or using the command line:
>
> Use the portal to create an Azure AD application and service principal that can access resources
>
> Use Azure PowerShell to create a service principal with a certificate

Step 3: Create a secret for your app registration

Your secret will be used along with your Azure AppId/ClientId when requesting an access token to send push notifications.



Navigate to **Certificates & secrets** and select **New client secret**.

> **Important**
>
> Ensure you copy your secret once created and store it in a safe location, like Azure Key Vault. It will only be viewable once right after creation.

Step 4: Map your app's Package Family Name to its Azure AppId

If your app is packaged (including packaged with an external location), you can use this flow to map your app's Package Family Name (PFN) and its Azure AppId.

If your app is a packaged Win32 app, then create a Package Family Name (PFN) mapping request by emailing Win_App_SDK_Push@microsoft.com with subject line "Windows App SDK Push Notifications Mapping Request" and body "PFN: [your PFN]", AppId: [your APPId], ObjectId: [your ObjectId]. Mapping requests are completed on a weekly basis. You will be notified once your mapping request has been completed.

Configure your app to receive push notifications

Step 1: Add namespace declarations

Add the namespace for Windows App SDK push notifications `Microsoft.Windows.PushNotifications`.

C++

```
#include <winrt/Microsoft.Windows.PushNotifications.h>

using namespace winrt::Microsoft::Windows::PushNotifications;
```

Step 2: Add your COM activator to your app's manifest

> **Important**
>
> If your app is unpackaged (that is, it lacks package identity at runtime), then skip to **Step 3: Register for and respond to push notifications on app startup**.

If your app is packaged (including packaged with external location): Open your **Package.appxmanifest**. Add the following inside the `<Application>` element. Replace the `Id`, `Executable`, and `DisplayName` values with those specific to your app.

XAML

```
<!--Packaged apps only-->
<!--package.appxmanifest-->

<Package
  ...
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"
  ...
  <Applications>
    <Application>
      ...
      <Extensions>

        <!--Register COM activator-->
        <com:Extension Category="windows.comServer">
          <com:ComServer>
              <com:ExeServer Executable="SampleApp\SampleApp.exe"
DisplayName="SampleApp" Arguments="----WindowsAppRuntimePushServer:">
                <com:Class Id="[Your app's Azure AppId]"
DisplayName="Windows App SDK Push" />
            </com:ExeServer>
          </com:ComServer>
        </com:Extension>

      </Extensions>
    </Application>
  </Applications>
 </Package>
```

Step 3: Register for and respond to push notifications on app startup

Update your app's `main()` method to add the following:

1. Register your app to receive push notifications by calling PushNotificationManager::Default().Register().
2. Check the source of the activation request by calling AppInstance::GetCurrent().GetActivatedEventArgs(). If the activation was triggered from a push notification, respond based on the notification's payload.

> **ⓘ Important**

You must call **PushNotificationManager::Default().Register** before calling [AppInstance.GetCurrent.GetActivatedEventArgs](#).

The following sample is from the sample packaged app found on GitHub.

C++

```
// cpp-console.cpp
#include "pch.h"
#include <iostream>
#include <winrt/Microsoft.Windows.PushNotifications.h>
#include <winrt/Microsoft.Windows.AppLifecycle.h>
#include <winrt/Windows.Foundation.h>
#include <wil/result.h>
#include <wil/cppwinrt.h>

using namespace winrt;
using namespace Windows::Foundation;

using namespace winrt::Microsoft::Windows::PushNotifications;
using namespace winrt::Microsoft::Windows::AppLifecycle;

winrt::guid remoteId{ "7edfab6c-25ae-4678-b406-d1848f97919a" }; // Replace
this with your own Azure ObjectId

void SubscribeForegroundEventHandler()
{
    winrt::event_token token{
PushNotificationManager::Default().PushReceived([](auto const&,
PushNotificationReceivedEventArgs const& args)
    {
        auto payload{ args.Payload() };

        std::string payloadString(payload.begin(), payload.end());
        std::cout << "\nPush notification content received in the
FOREGROUND: " << payloadString << std::endl;
    }) };
}

int main()
{
    // Setup an event handler, so we can receive notifications in the
foreground while the app is running.
    SubscribeForegroundEventHandler();

    PushNotificationManager::Default().Register();

    auto args{ AppInstance::GetCurrent().GetActivatedEventArgs() };
    switch (args.Kind())
    {
```

```
        // When it is launched normally (by the users, or from the
debugger), the sample requests a WNS Channel URI and
        // displays it, then waits for notifications. This user can take a
copy of the WNS Channel URI and use it to send
        // notifications to the sample
        case ExtendedActivationKind::Launch:
        {
            // Checks to see if push notifications are supported. Certain
self-contained apps may not support push notifications by design
            if (PushNotificationManager::IsSupported())
            {
                // Request a WNS Channel URI which can be passed off to an
external app to send notifications to.
                // The WNS Channel URI uniquely identifies this app for this
user and device.
                PushNotificationChannel channel{ RequestChannel() };
                if (!channel)
                {
                    std::cout << "\nThere was an error obtaining the WNS
Channel URI" << std::endl;

                    if (remoteId == winrt::guid { "00000000-0000-0000-0000-
000000000000" })
                    {
                        std::cout << "\nThe ObjectID has not been set. Refer
to the readme file accompanying this sample\nfor the instructions on how to
obtain and setup an ObjectID" << std::endl;
                    }
                }

                std::cout << "\nPress 'Enter' at any time to exit App." <<
std::endl;
                std::cin.ignore();
            }
            else
            {
                // App implements its own custom socket here to receive
messages from the cloud since Push APIs are unsupported.
            }
        }
        break;

        // When it is activated from a push notification, the sample only
displays the notification.
        // It doesn't register for foreground activation of perform any
other actions
        // because background activation is meant to let app perform only
small tasks in order to preserve battery life.
        case ExtendedActivationKind::Push:
        {
            PushNotificationReceivedEventArgs pushArgs{
args.Data().as<PushNotificationReceivedEventArgs>() };

            // Call GetDeferral to ensure that code runs in low power
            auto deferral{ pushArgs.GetDeferral() };
```

```
            auto payload{ pushArgs.Payload() } ;

            // Do stuff to process the raw notification payload
            std::string payloadString(payload.begin(), payload.end());
            std::cout << "\nPush notification content received in the
BACKGROUND: " << payloadString.c_str() << std::endl;
            std::cout << "\nPress 'Enter' to exit the App." << std::endl;

            // Call Complete on the deferral when finished processing the
payload.
            // This removes the override that kept the app running even when
the system was in a low power mode.
            deferral.Complete();
            std::cin.ignore();
        }
        break;

        default:
            std::cout << "\nUnexpected activation type" << std::endl;
            std::cout << "\nPress 'Enter' to exit the App." << std::endl;
            std::cin.ignore();
            break;
    }

    // We do not call PushNotificationManager::UnregisterActivator
    // because then we wouldn't be able to receive background activations,
once the app has closed.
    // Call UnregisterActivator once you don't want to receive push
notifications anymore.
}
```

Step 4: Request a WNS Channel URI and register it with the WNS server

WNS Channel URIs are the HTTP endpoints for sending push notifications. Each client must request a Channel URI and register it with the WNS server to receive push notifications.

> ⓘ **Note**
>
> WNS Channel URIs expire after 30 days.

C++

```
auto channelOperation{
PushNotificationManager::Default().CreateChannelAsync(winrt::guid("[Your
```

```
app's Azure ObjectID]")) };
```

The **PushNotificationManager** will attempt to create a Channel URI, retrying automatically for no more than 15 minutes. Create an event handler to wait for the call to complete. Once the call is complete, if it was successful, register the URI with the WNS server.

C++

```
// cpp-console.cpp

winrt::Windows::Foundation::IAsyncOperation<PushNotificationChannel>
RequestChannelAsync()
{
    // To obtain an AAD RemoteIdentifier for your app,
    // follow the instructions on https://learn.microsoft.com/azure/active-
directory/develop/quickstart-register-app
    auto channelOperation =
PushNotificationManager::Default().CreateChannelAsync(remoteId);

    // Setup the inprogress event handler
    channelOperation.Progress(
        [](auto&& sender, auto&& args)
        {
            if (args.status == PushNotificationChannelStatus::InProgress)
            {
                // This is basically a noop since it isn't really an error
state
                std::cout << "Channel request is in progress." << std::endl
<< std::endl;
            }
            else if (args.status ==
PushNotificationChannelStatus::InProgressRetry)
            {
                LOG_HR_MSG(
                    args.extendedError,
                    "The channel request is in back-off retry mode because
of a retryable error! Expect delays in acquiring it. RetryCount = %d",
                    args.retryCount);
            }
        });

    auto result = co_await channelOperation;

    if (result.Status() == PushNotificationChannelStatus::CompletedSuccess)
    {
        auto channelUri = result.Channel().Uri();

        std::cout << "channelUri: " <<
winrt::to_string(channelUri.ToString()) << std::endl << std::endl;

        auto channelExpiry = result.Channel().ExpirationTime();
```

```
        // Caller's responsibility to keep the channel alive
        co_return result.Channel();
    }
    else if (result.Status() ==
PushNotificationChannelStatus::CompletedFailure)
    {
        LOG_HR_MSG(result.ExtendedError(), "We hit a critical non-retryable
error with channel request!");
        co_return nullptr;
    }
    else
    {
        LOG_HR_MSG(result.ExtendedError(), "Some other failure occurred.");
        co_return nullptr;
    }

};

PushNotificationChannel RequestChannel()
{
    auto task = RequestChannelAsync();
    if (task.wait_for(std::chrono::seconds(300)) != AsyncStatus::Completed)
    {
        task.Cancel();
        return nullptr;
    }

    auto result = task.GetResults();
    return result;
}
```

Step 5: Build and install your app

Use Visual Studio to build and install your app. Right click on the solution file in the Solution Explorer and select **Deploy**. Visual Studio will build your app and install it on your machine. You can run the app by launching it via the Start Menu or the Visual Studio debugger.

Send a push notification to your app

At this point, all configuration is complete and the WNS server can send push notifications to client apps. In the following steps, refer to the Push notification server request and response headers for more detail.

Step 1: Request an access token

To send a push notification, the WNS server first needs to request an access token. Send an HTTP POST request with your Azure TenantId, Azure AppId, and secret. For information on retrieving the Azure TenantId and Azure AppId, see Get tenant and app ID values for signing in.

HTTP Sample Request:

```HTTP
POST /{tenantID}/oauth2/v2.0/token Http/1.1
Host: login.microsoftonline.com
Content-Type: application/x-www-form-urlencoded
Content-Length: 160

grant_type=client_credentials&client_id=
<Azure_App_Registration_AppId_Here>&client_secret=
<Azure_App_Registration_Secret_Here>&scope=https://wns.windows.com/.default/
```

C# Sample Request:

```C#
//Sample C# Access token request
var client = new
RestClient("https://login.microsoftonline.com/{tenantID}/oauth2/v2.0");
var request = new RestRequest("/token", Method.Post);
request.AddHeader("Content-Type", "application/x-www-form-urlencoded");
request.AddParameter("grant_type", "client_credentials");
request.AddParameter("client_id", "[Your app's Azure AppId]");
request.AddParameter("client_secret", "[Your app's secret]");
request.AddParameter("scope", "https://wns.windows.com/.default");
RestResponse response = await client.ExecutePostAsync(request);
Console.WriteLine(response.Content);
```

If your request is successful, you will receive a response that contains your token in the **access_token** field.

```JSON
{
    "token_type":"Bearer",
    "expires_in":"86399",
    "ext_expires_in":"86399",
    "expires_on":"1653771789",
    "not_before":"1653685089",
    "access_token":"[your access token]"
}
```

Step 2. Send a raw notification

Create an HTTP POST request that contains the access token you obtained in the previous step and the content of the push notification you want to send. The content of the push notification will be delivered to the app.

HTTP

```
POST /?token=[The token query string parameter from your channel URL. E.g. AwYAAABa5cJ3...] HTTP/1.1
Host: dm3p.notify.windows.com
Content-Type: application/octet-stream
X-WNS-Type: wns/raw
Authorization: Bearer [your access token]
Content-Length: 46

{ Sync: "Hello from the Contoso App Service" }
```

C#

```
var client = new RestClient("[Your channel URL. E.g. https://wns2-by3p.notify.windows.com/?token=AwYAAABa5cJ3...]");
var request = new RestRequest();
request.Method = Method.Post;
request.AddHeader("Content-Type", "application/octet-stream");
request.AddHeader("X-WNS-Type", "wns/raw");
request.AddHeader("Authorization", "Bearer [your access token]");
request.AddBody("Notification body");
RestResponse response = await client.ExecutePostAsync(request);");
```

Step 3: Send a cloud-sourced app notification

If you are only interested in sending raw notifications, disregard this step. To send a cloud-sourced app notification, also known a push toast notification, first follow Quickstart: App notifications in the Windows App SDK. App notifications can either be push (sent from the cloud) or sent locally. Sending a cloud-sourced app notification is similar to sending a raw notification in **Step 2**, except the *X-WNS-Type* header is `toast`, *Content-Type* is `text/xml`, and the content contains the app notification XML payload. See Notifications XML schema for more on how to construct your XML payload.

Create an HTTP POST request that contains your access token and the content of the cloud-sourced app notification you want to send. The content of the push notification will be delivered to the app.

HTTP

```
POST /?
token=AwYAAAB%2fQAhYEiAESPobjHzQcwGCTjHu%2f%2fP3CCNDcyfyvgbK5xD3kztniW%2bjba
1b3aSSun58SA326GMxuzZooJYwtpgzL9AusPDES2alyQ8CHvW94cO5VuxxLDVzrSzdO1ZVgm%2bN
SB9BAzOASvHqkMHQhsDy HTTP/1.1
Host: dm3p.notify.windows.com
Content-Type: text/xml
X-WNS-Type: wns/toast
Authorization: Bearer [your access token]
Content-Length: 180

<toast><visual><binding template="ToastGeneric"><text>Example cloud toast
notification</text><text>This is an example cloud notification using
XML</text></binding></visual></toast>
```

C#

```
var client = new RestClient("https://dm3p.notify.windows.com/?
token=AwYAAAB%2fQAhYEiAESPobjHzQcwGCTjHu%2f%2fP3CCNDcyfyvgbK5xD3kztniW%2bjba
1b3aSSun58SA326GMxuzZooJYwtpgzL9AusPDES2alyQ8CHvW94cO5VuxxLDVzrSzdO1ZVgm%2bN
SB9BAzOASvHqkMHQhsDy");
client.Timeout = -1;

var request = new RestRequest(Method.POST);
request.AddHeader("Content-Type", "text/xml");
request.AddHeader("X-WNS-Type", "wns/toast");
request.AddHeader("Authorization", "Bearer <AccessToken>");
request.AddParameter("text/xml", "<toast><visual><binding
template=\"ToastGeneric\"><text>Example cloud toast notification</text>
<text>This is an example cloud notification using XML</text></binding>
</visual></toast>",  ParameterType.RequestBody);
Console.WriteLine(response.Content);
```

Troubleshooting push notifications

Article • 06/03/2022

WNS channel request errors

In case the **CreateChannelAsync** call fails, these are the common HRESULTS and our recommended actions.

HRESULT	Definition	Description
0x880403E8L	WNP_E_NOT_CONNECTED	The app is not connected to the WNS Server after retries.
0x880403E9L	WNP_E_RECONNECTING	The app is in the process of reconnecting to the WNS Server. Try requesting a channelURI again after several minutes.
0x880403FEL	WNP_E_BIND_USER_BUSY	The WNS client is having connectivity issues with the WNS server. Try requesting a channelURI again after several minutes.

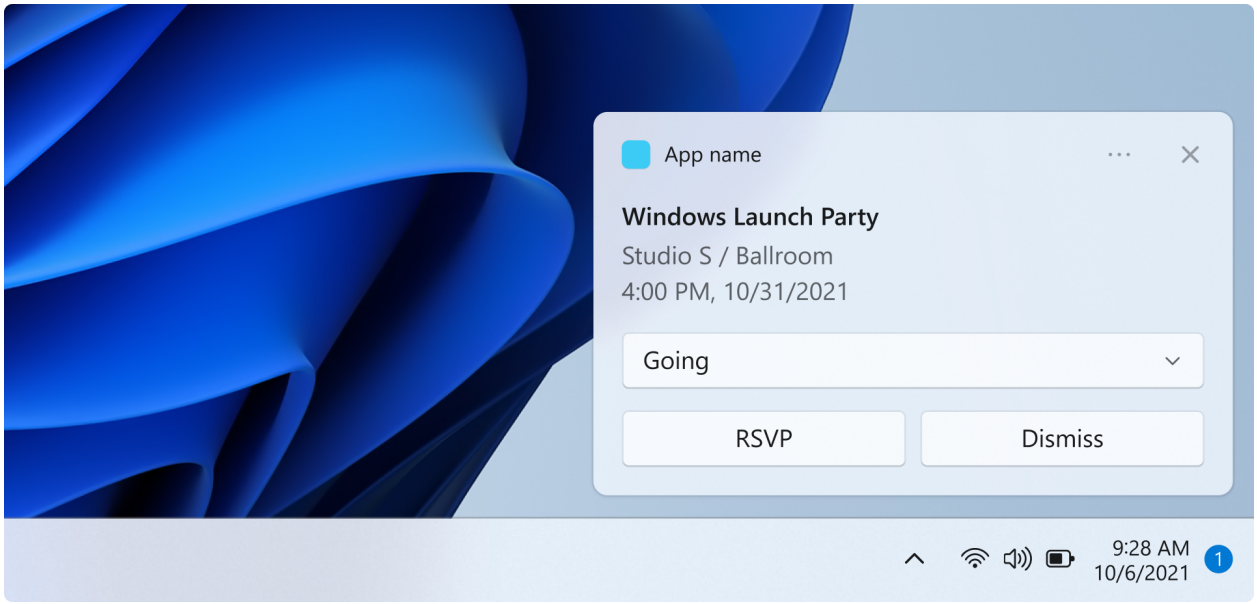
WNS HTTP response codes

HTTP response code	Description	Recommended action
200 Ok	The notification was accepted by WNS.	None required.
400 Bad Request	One or more headers were specified incorrectly or conflict with another header.	Log the details of your request. Inspect your request and compare against this documentation.
401 Unauthorized	The cloud service did not present a valid authentication ticket. The OAuth ticket may be invalid.	Request a valid access token by authenticating your cloud service using the access token request.
403 Forbidden	The cloud service is not authorized to send a notification to this URI even though they are authenticated.	The access token provided in the request does not match the credentials of the app that requested the channel URI. Ensure that your package name in your app's manifest matches

HTTP response code	Description	Recommended action
		the cloud service credentials given to your app in the Dashboard.
404 Not Found	The channel URI is not valid or is not recognized by WNS.	Log the details of your request. Do not send further notifications to this channel; notifications to this address will fail.
405 Method Not Allowed	Invalid method (GET, CREATE); only POST	Log the details of your request. Switch to using HTTP POST.
406 Not Acceptable	The cloud service exceeded its throttle limit.	Log the details of your request. Reduce the rate at which you are sending notifications.
410 Gone	The channel expired.	Log the details of your request. Do not send further notifications to this channel. Have your app request a new channel URI.
413 Request Entity Too Large	The notification payload exceeds the 5000 byte size limit.	Log the details of your request. Inspect the payload to ensure it is within the size limitations.
429 Monthly Quota Exceeded	The app is over the monthly quota limit.	Wait until monthly quota limit is reset or move to a higher WNS tier.
500 Internal Server Error	An internal failure caused notification delivery to fail.	Log the details of your request. Report this issue in the Windows App SDK Issues with the *area-Notifications* label.
503 Service Unavailable	The server is currently unavailable.	Log the details of your request. Report this issue in the Windows App SDK Issues with the *area-Notifications* label.

App notifications overview

Article • 07/12/2022



App notifications in the Windows App SDK are messages that your app can construct and deliver to your user while they are not currently inside your app. The notification content is displayed in a transient window in the bottom right corner of the screen and in the Notification Center (called Action Center in Windows 10). App notifications can be used to inform the user of application status or state changes, or to prompt the user to take an action. App notifications can either be sent locally or from a cloud service using push notifications.

Limitations

The app notifications support in the Windows App SDK currently has these limitations:

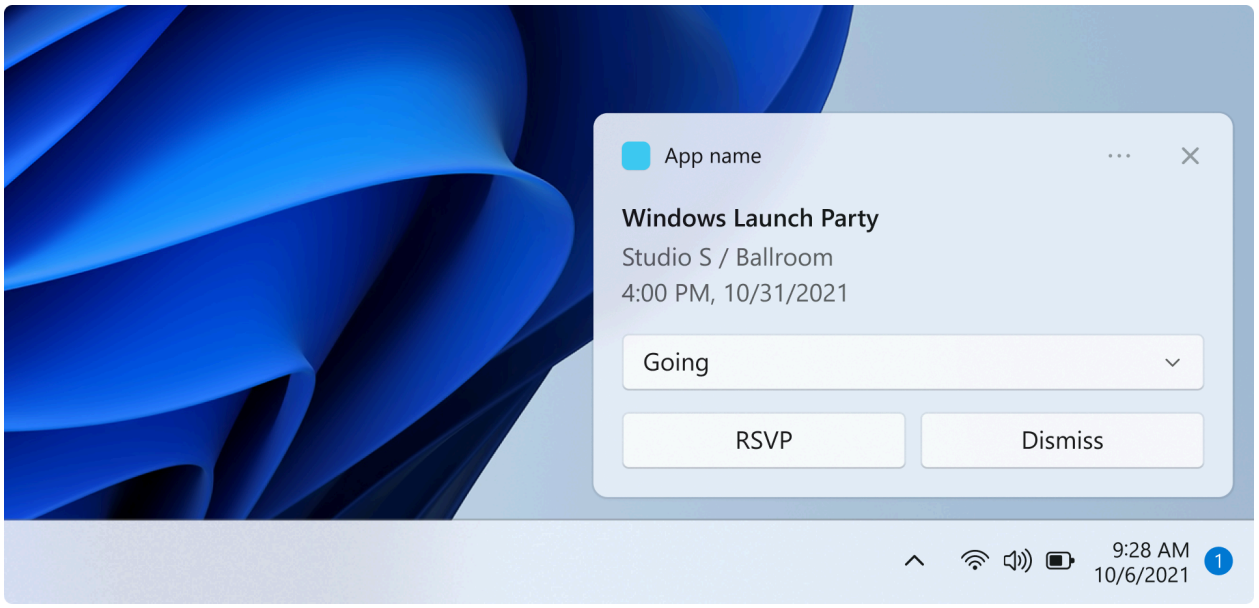
- Notifications for an elevated (admin) app are currently not supported.

Next steps

See Quickstart: App notifications in the Windows App SDK to get started.

Quickstart: App notifications in the Windows App SDK

Article • 03/10/2023



In this quickstart, you will create a desktop Windows application that sends and receives local app notifications, also known as toast notifications, using the Windows App SDK.

> **Important**
>
> Notifications for an elevated (admin) app is currently not supported.

Prerequisites

- Get started with WinUI
- Either Create a new project that uses the Windows App SDK OR Use the Windows App SDK in an existing project

Sample app

This quickstart covers code from the notifications sample apps found on GitHub.

Sample App Code

API reference

For API reference documentation for app notifications, see Microsoft.Windows.AppNotifications Namespace.

Step 1: Add namespace declarations

Add the namespace for Windows App SDK app notifications `Microsoft.Windows.AppNotifications`.

```
C#

using Microsoft.Windows.AppNotifications;
```

Step 2: Update your app's manifest

If your app is unpackaged (that is, it lacks package identity at runtime), then skip to **Step 3: Register to handle an app notification**.

If your app is packaged (including packaged with external location):

1. Open your **Package.appxmanifest**.
2. Add `xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"` and `xmlns:desktop="http://schemas.microsoft.com/appx/manifest/desktop/windows10"` namespaces to `<Package>`
3. Add `<desktop:Extension>` for `windows.toastNotificationActivation` to declare your COM activator CLSID. You can obtain a CLSID by navigating to **Create GUID** under **Tools** in Visual Studio.
4. Add `<com:Extension>` for the COM activator using the same CLSID.
   a. Specify your .exe file in the `Executable` attribute. The .exe file must be the same process calling `Register()` when registering your app for notifications, which is described more in **Step 3**. In the example below, we use `Executable="SampleApp\SampleApp.exe"`.
   b. Specify `Arguments="----AppNotificationActivated:"` to ensure that Windows App SDK can process your notification's payload as an AppNotification kind.
   c. Specify a `DisplayName`.

> **ⓘ Important**

Warning: If you define a Windows.Protocol app extensibility type in your appx manifest with `<uap:Protocol>`, then clicking on notifications will launch new processes of the same app, even if your app is already running.

XAML

```
<!--Packaged apps only-->
<!--package.appxmanifest-->

<Package
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"

xmlns:desktop="http://schemas.microsoft.com/appx/manifest/desktop/windows10"
  ...
  <Applications>
    <Application>
      ...
      <Extensions>

        <!--Specify which CLSID to activate when notification is clicked-->
        <desktop:Extension Category="windows.toastNotificationActivation">
          <desktop:ToastNotificationActivation
ToastActivatorCLSID="replaced-with-your-guid-C173E6ADF0C3" />
        </desktop:Extension>

        <!--Register COM CLSID-->
        <com:Extension Category="windows.comServer">
          <com:ComServer>
            <com:ExeServer Executable="SampleApp\SampleApp.exe"
DisplayName="SampleApp" Arguments="----AppNotificationActivated:">
              <com:Class Id="replaced-with-your-guid-C173E6ADF0C3" />
            </com:ExeServer>
          </com:ComServer>
        </com:Extension>

      </Extensions>
    </Application>
  </Applications>
 </Package>
```

Step 3: Register to handle an app notification

Register your app to handle notifications, then unregister when your app terminates.

In your `App.xaml` file, register for AppNotificationManager::Default().NotificationInvoked, then call AppNotificationManager::Default().Register. The order of these calls matters.

ⓘ Important

You must call **AppNotificationManager::Default().Register** before calling AppInstance.GetCurrent.GetActivatedEventArgs.

When your app is terminating, call AppNotificationManager::Default().Unregister() to free up the COM server and allow for subsequent invokes to launch a new process.

C#

cs

```
// App.xaml.cs
namespace CsUnpackagedAppNotifications
{

    public partial class App : Application
    {
        private Window mainWindow;
        private NotificationManager notificationManager;

        public App()
        {
            this.InitializeComponent();
            notificationManager = new NotificationManager();
            AppDomain.CurrentDomain.ProcessExit += new
EventHandler(OnProcessExit);
        }

        protected override void OnLaunched(LaunchActivatedEventArgs
args)
        {
            mainWindow = new MainWindow();

            notificationManager.Init();

            // Complete in Step 5

            mainWindow.Activate();
        }

        void OnProcessExit(object sender, EventArgs e)
        {
            notificationManager.Unregister();
        }
    }
}

// NotificationManager.cs
namespace CsUnpackagedAppNotifications
{
    internal class NotificationManager
```

```
    {
        private bool m_isRegistered;

        private Dictionary<int,
Action<AppNotificationActivatedEventArgs>> c_map;

        public NotificationManager()
        {
            m_isRegistered = false;

            // When adding new a scenario, be sure to add its
notification handler here.
            c_map = new Dictionary<int,
Action<AppNotificationActivatedEventArgs>>();
            c_map.Add(ToastWithAvatar.ScenarioId,
ToastWithAvatar.NotificationReceived);
            c_map.Add(ToastWithTextBox.ScenarioId,
ToastWithTextBox.NotificationReceived);
        }

        ~NotificationManager()
        {
            Unregister();
        }

        public void Init()
        {
            // To ensure all Notification handling happens in this
process instance, register for
            // NotificationInvoked before calling Register(). Without
this a new process will
            // be launched to handle the notification.
            AppNotificationManager notificationManager =
AppNotificationManager.Default;

            notificationManager.NotificationInvoked +=
OnNotificationInvoked;

            notificationManager.Register();
            m_isRegistered = true;
        }

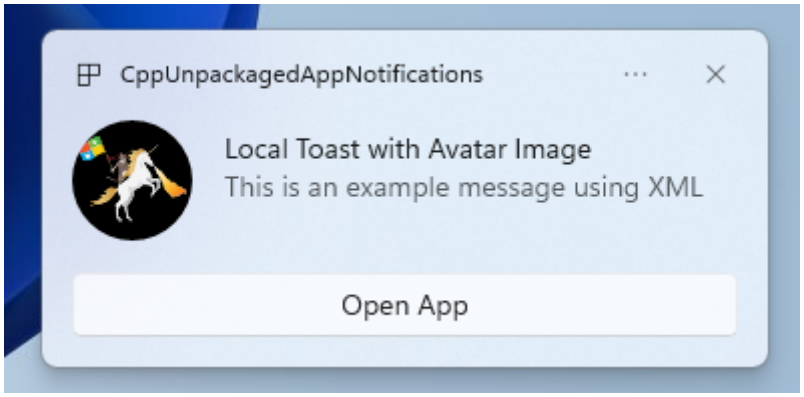
        public void Unregister()
        {
            if (m_isRegistered)
            {
                AppNotificationManager.Default.Unregister();
                m_isRegistered = false;
            }
        }

        public void
ProcessLaunchActivationArgs(AppNotificationActivatedEventArgs
notificationActivatedEventArgs)
        {
```

```
            // Complete in Step 5
        }

    }
}
```

Step 4: Display an app notification



You **MUST** complete **Step 3: Register to handle an app notification** before proceeding.

Now you will display a simple app notification with an `appLogoOverride` image and a button.

Construct your app notification using the **AppNotificationBuilder** class and then call `Show`. For more information on how to construct your app notification using XML, please refer to the examples at Toast content and the Notifications XML schema.

> **Note**
>
> If your app is packaged (including packaged with external location), then your app's icon in the notification's upper left corner is sourced from the `package.manifest`. If your app is unpackaged, then the icon is sourced by first looking into the shortcut, then looking at the resource file in the app process. If all attempts fail, then the Windows default app icon is used. The supported icon file types are `.jpg`, `.png`, `.bmp`, and `.ico`.

C#

C#

```
// ToastWithAvatar.cs
class ToastWithAvatar
```

```
{
    public const int ScenarioId = 1;
    public const string ScenarioName = "Local Toast with Avatar Image";

    public static bool SendToast()
    {
        var appNotification = new AppNotificationBuilder()
            .AddArgument("action", "ToastClick")
            .AddArgument(Common.scenarioTag, ScenarioId.ToString())
            .SetAppLogoOverride(new System.Uri("file://" +
App.GetFullPathToAsset("Square150x150Logo.png")),
AppNotificationImageCrop.Circle)
            .AddText(ScenarioName)
            .AddText("This is an example message using XML")
            .AddButton(new AppNotificationButton("Open App")
                .AddArgument("action", "OpenApp")
                .AddArgument(Common.scenarioTag, ScenarioId.ToString()))
            .BuildNotification();

        AppNotificationManager.Default.Show(appNotification);

        return appNotification.Id != 0; // return true (indicating
success) if the toast was sent (if it has an Id)
    }

    public static void
NotificationReceived(AppNotificationActivatedEventArgs
notificationActivatedEventArgs)
    {
        // Complete in Step 5
    }
}

// Call SendToast() to send a notification.
```

Step 5: Process a user selecting a notification

Users can select your notification's body or button. Your app needs to process the invocation in response to a user interacting with your notification.

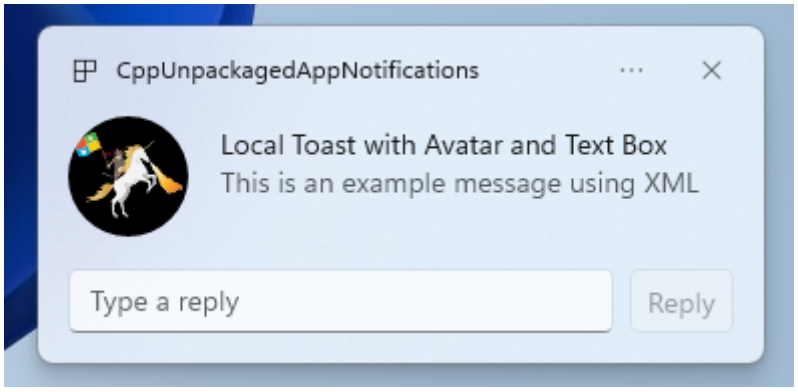
There are 2 common ways to process this:

1. You choose to have your app launch in a specific UI context OR
2. You choose to have your app evaluate an action-specific behavior (like a button press in the notification body) without rendering any UI. Also known as a background action.

The code example below, which is not from the sample app, illustrates both ways of processing a user-generated action. Add a `launch` value (corresponds to user clicking

the notification body), an `input` element (quick reply text box), and a button with an `arguments` value (corresponds to user clicking the button) to your notification's XML payload. In your `ProcessLaunchActivationArgs`, case on each argument.

> **ⓘ Important**
>
> Setting `activationType="background"` in the notification XML payload is ignored for desktop apps. You must instead process the activation arguments and decide whether to display a window or not, as stated in this step.



C++

```
// Example of how to process a user either selecting the notification body
or inputting a quick reply in the text box.

// Notification XML payload
//<toast launch="action=openThread&amp;threadId=92187">
//  <visual>
//      <binding template="ToastGeneric">
//          <image placement="appLogoOverride" hint-crop="circle" src="C:\
<fullpath>\Logo.png"/>
//          <text>Local Toast with Avatar and Text box</text>
//          <text>This is an example message using</text>
//      </binding>
//  </visual>
//  <actions>
//      <input id="replyBox" type="text" placeHolderContent="Reply" />
//      <action
//          content="Send"
//          hint-inputId="replyBox"
//          arguments="action=reply&amp;threadId=92187" />
//  </actions>
//</toast>

void ProcessLaunchActivationArgs(const
winrt::AppNotificationActivatedEventArgs& notificationActivatedEventArgs)
{
    // If the user clicks on the notification body, your app needs to launch
the chat thread window
```

```
    if
(std::wstring(notificationActivatedEventArgs.Argument().c_str()).find(L"open
Thread") != std::wstring::npos)
    {
        GenerateChatThreadWindow();
    }
    else // If the user responds to a message by clicking a button in the
notification, your app needs to reply back to the other user with no window
launched
    if
(std::wstring(notificationActivatedEventArgs.Argument().c_str()).find(L"repl
y") != std::wstring::npos)
    {
        auto input = notificationActivatedEventArgs.UserInput();
        auto replyBoxText = input.Lookup(L"replyBox");

        // Process the reply text
        SendReplyToUser(replyBoxText);
    }
}
```

Follow the below guidelines:

1. If a notification is selected by the user and your app is not running, it is expected that your app is launched and the user can see the foreground window in the notification's context.
2. If a notification is selected by the user and your app is minimized, it is expected that your app is brought to the foreground and a new window is rendered in the notification's context.
3. If a notification background action is invoked by the user (e.g. the user responds to a notification by typing in the notification text box and hitting reply), your app processes the payload without rendering a foreground window.

See the sample app code found on GitHub for a more detailed example.

Step 6: Remove notifications

Remove notifications when they are no longer relevant to the user.

In this example, the user has seen all messages from a group chat in your app, so you clear all notifications from the group chat. Then, the user mutes a friend, so you clear all notifications from the friend. You first added the **Group** and **Tag** properties to the notifications before displaying in order to identify them now.

```
C++
```

```
void SendNotification(winrt::hstring const& payload, winrt::hstring const&
friendId, winrt::hstring const& groupChatId)
{
    winrt::AppNotification notification(payload);

    // Setting Group Id here allows clearing notifications from a specific
chat group later
    notification.Group(groupChatId);

    // Setting Tag Id here allows clearing notifications from a specific
friend later
    notification.Tag(friendId);

    winrt::AppNotificationManager::Default().Show(notification);
}

winrt::Windows::Foundation::IAsyncAction
RemoveAllNotificationsFromGroupChat(const std::wstring groupChatId)
{
    winrt::AppNotificationManager manager =
winrt::AppNotificationManager::Default();
    co_await manager.RemoveByGroupAsync(groupChatId);
}

winrt::Windows::Foundation::IAsyncAction
RemoveAllNotificationsFromFriend(const std::wstring friendId)
{
    winrt::AppNotificationManager manager =
winrt::AppNotificationManager::Default();
    co_await manager.RemoveByTagAsync(friendId);
}
```

Additional features

Send a cloud-sourced app notification

To send an app notification from the cloud, follow **Send a cloud-sourced app notification** at Quickstart: Push notifications in the Windows App SDK.

Set an expiration time

Set an expiration time on your app notification using the `Expiration` property if the message in your notification is only relevant for a certain period of time. For example, if you send a calendar event reminder, set the expiration time to the end of the calendar event.

> **Note**
>
> The default and maximum expiration time is 3 days.

C#

```
class ToastWithAvatar
{
    public static bool SendToast()
    {

        var appNotification = new AppNotificationBuilder()
            .SetAppLogoOverride(new System.Uri("ms-
appx:///images/logo.png"), AppNotificationImageCrop.Circle)
            .AddText("Example expiring notification")
            .AddText("This is an example message")
            .BuildNotification();

        appNotification.Expiration = DateTime.Now.AddDays(1);
        AppNotificationManager.Default.Show(appNotification);

        return appNotification.Id != 0; // return true (indicating success)
if the toast was sent (if it has an Id)
    }
}
```

Ensure notifications expire on reboot

Set the `ExpiresOnReboot` property to **True** if you'd like notifications to delete on reboot.

C#

C#

```
class ToastWithAvatar
{
    public static bool SendToast()
    {

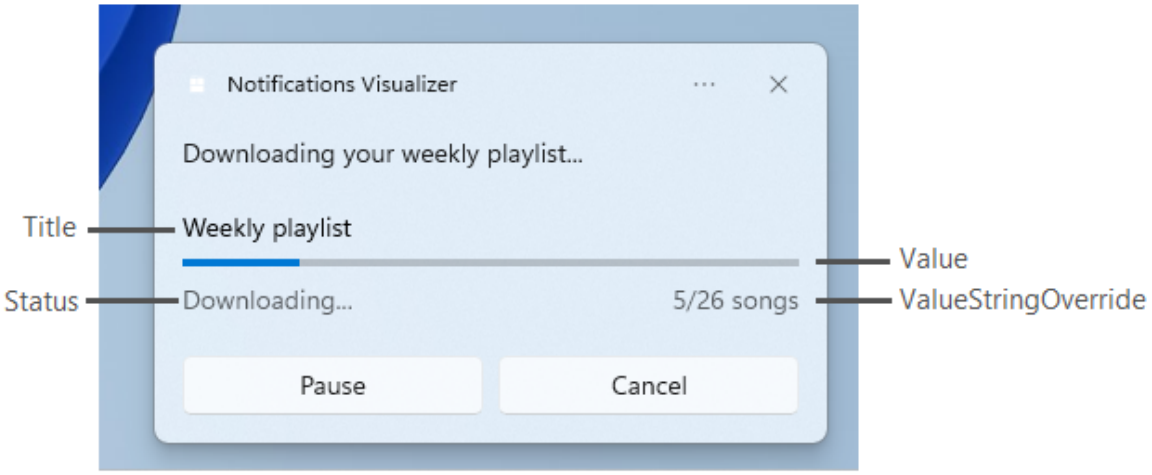
        var appNotification = new AppNotificationBuilder()
            .SetAppLogoOverride(new System.Uri("ms-
appx:///images/logo.png"), AppNotificationImageCrop.Circle)
            .AddText("Example ExpiresOnReboot notification")
            .AddText("This is an example message")
            .BuildNotification();
```

```
            appNotification.ExpiresOnReboot = true;
            AppNotificationManager.Default.Show(appNotification);

            return appNotification.Id != 0; // return true (indicating
success) if the toast was sent (if it has an Id)
        }
    }
```

Send and update a progress bar notification

You can display progress bar related updates in a notification:



Use the `AppNotificationProgressData` construct to update the progress bar notification.

C++

```
const winrt::hstring c_tag = L"weekly-playlist";
const winrt::hstring c_group = L"downloads";

// Send first Notification Progress Update
void SendUpdatableNotificationWithProgress()
{
    auto notification{ winrt::AppNotificationBuilder()
            .AddText(L"Downloading this week's new music...")
            .AddProgressBar(winrt::AppNotificationProgressBar()
                .BindTitle()
                .BindValue()
                .BindValueStringOverride()
                .BindStatus())
            .BuildNotification() }

    notification.Tag(c_tag);
    notification.Group(c_group);

    // Assign initial values for first notification progress UI
    winrt::AppNotificationProgressData data(1); // Sequence number
    data.Title(L"Weekly playlist"); // Binds to {progressTitle} in xml
```

```
payload
    data.Value(0.6); // Binds to {progressValue} in xml payload
    data.ValueStringOverride(L"15/26 songs"); // Binds to
{progressValueString} in xml payload
    data.Status(L"Downloading..."); // Binds to {progressStatus} in xml
payload

    notification.Progress(data);
    winrt::AppNotificationManager::Default().Show(notification);
}

// Send subsequent progress updates
winrt::Windows::Foundation::IAsyncAction UpdateProgressAsync()
{
    // Assign new values
    winrt::AppNotificationProgressData data(2 /* Sequence number */ );
    data.Title(L"Weekly playlist"); // Binds to {progressTitle} in xml
payload
    data.Value(0.7); // Binds to {progressValue} in xml payload
    data.ValueStringOverride(L"18/26 songs"); // Binds to
{progressValueString} in xml payload
    data.Status(L"Downloading..."); // Binds to {progressStatus} in xml
payload

    auto result = co_await
winrt::AppNotificationManager::Default().UpdateAsync(data, c_tag, c_group);
    if (result ==
winrt::AppNotificationProgressResult::AppNotificationNotFound)
    {
        // Progress Update failed since the previous notification update was
dismissed by the user! So account for this in your logic by stopping updates
or starting a new Progress Update flow.
    }
}
```

Integrate with Windows

Article • 11/22/2024

This section of the documentation provides developer guidance for integrating with Windows.

Windows system components that support 3rd party integration

The following table lists the Windows system components that support integration for 3rd party developers.

Expand table

Feature	Description
Feed providers	Learn how to integrate into the Windows feeds experience.
Microsoft Copilot hardware key providers	Learn how to integrate into the Windows feeds experience.
Search providers	Learn how to integrate into the Windows Search experience.
Widget providers	Learn how to implement a Windows widget service provider to support your app.

Other Windows integration features

Expand table

Feature	Description
Smart App Control	Smart App Control is a new app execution control feature that combines Microsoft's app intelligence services and Windows' code integrity features to protect users from untrusted or potentially dangerous code.
Windows Share integration	The Windows Share Sheet is a system-provided UI that enables users to share content from your app with other apps.
Windows People experiences	Learn how third party apps can integrate with Windows People experiences using APIs to store their contacts.

Microsoft Copilot hardware key providers

Article • 03/31/2025

Starting with Windows Build 22621, apps can register to be included in the picker UI that allows users to select the app that is launched when the Microsoft Copilot hardware key or the Windows key + C is pressed.

> **Note**
>
> It is recommended that apps that register to be a Microsoft Copilot hardware key provider be implemented as single-window apps.

Microsoft Copilot hardware key app extension

An app must be packaged in order to register as a Microsoft Copilot hardware key provider. For information on app packaging, see An overview of Package Identity in Windows app. The app package manifest file, `Package.appxmanifest`, supports many different extensions and features for Windows apps. The app package manifest format is defined by a set of schemas that are documented in the Package manifest schema reference. Microsoft Copilot hardware key providers declare their registration information within the uap3:AppExtension. The **Name** attribute of the extension must be set to "com.microsoft.windows.copilotkeyprovider".

XML

```
<Package
...

```

The following table *uap3:AppExtension* describes the attributes of the **uap3:AppExtension** element.

Expand table

Attribute	Description	Required
Id	The app-defined identifier for the app.	Yes
DisplayName	The app name displayed in the Windows Copilot hardware button picker UI.	Yes
Description	The app description displayed in the Windows Copilot hardware button picker UI.	Yes
PublicFolder	The folder that the instance declares as the location where a host can have read access to files through a broker.	Yes

Sign your Windows Copilot hardware key provider

Provider apps must be signed in order to be enabled as a target of the Microsoft Copilot hardware key. For information on packaging and signing your app, see Package a desktop or UWP app in Visual Studio.

Handle Microsoft Copilot hardware key state changes

Article • 03/28/2025

This article describes how apps can register to be activated and receive notifications when the Microsoft Copilot hardware key or Windows key + C is pressed, pressed and held, and released. This feature enables apps to perform different actions depending on which key state change is detected. For example, an app may perform normal activation when the key is single-pressed, but take a screenshot when the key is pressed and held. Or, an app may begin recording audio and show a status indicator that audio is being recorded when the key is pressed and held, and then stop recording audio when the key is released. The key must be pressed and held for at least 300 ms to move into the held state.

This feature extends the features of a basic Microsoft Copilot hardware key provider, which simply registers to be launched when the hardware key is pressed. For more information, see Microsoft Copilot hardware key providers.

The rest of this article will walk through creating a simple C# WinUI 3 app that responds to activation initiated by a single press or a press and hold and release of the Microsoft Copilot button.

Create a new project

In Visual Studio, create a new project. For this example, in the **Create a new project** dialog, set the language filter to C# and the project type to WinUI 3 and then select the "Blank App, Packaged (WinUI 3 in Desktop).

Add a property to track the Microsoft Copilot key pressed state

In this example, we will create a property called **State** that we will use to display the current activation state in the UI. In `MainWindow.xaml.cs`, inside the definition of **MainWindow** add the following code to create a string property that we can bind to in our XAML file.

```
C#
```

```
// MainWindow.xaml.cs
public event PropertyChangedEventHandler? PropertyChanged;

private void OnPropertyChanged([CallerMemberName] string propertyName =
"State")
{
    PropertyChanged?.Invoke(this, new
PropertyChangedEventArgs(propertyName));
}

public void SetState(string state)
{
    State = state;
}

private string _state;
public string State
{
    get => _state;
    set
    {
        if (_state != value)
        {
            _state = value;
            OnPropertyChanged();
        }
    }
}
```

Add a **TextBox** control to the UI to show the current activation state of the app. Replace the default **StackPanel** element in MainPage.xaml with the following code.

XAML

```
<!-- MainWindow.xaml -->
<StackPanel Orientation="Horizontal" HorizontalAlignment="Center"
VerticalAlignment="Center">
    <TextBlock Name="KeyStateText" Text="{x:Bind State, Mode=OneWay}" />
</StackPanel>
```

Finally, update the **MainWindow** constructor to take an argument that will set the **State** property when the window is created.

C#

```
// MainWindow.xaml.cs
public MainWindow(string state)
{
    this.InitializeComponent();
```

```
    _state = state;
}
```

Register for URI activation

The system launches Microsoft Copilot hardware key providers using URI activation. Register a launch protocol by adding the uap:Protocol element to your app manifest. For more information about how to register as the default handler for a URI scheme, see Handle URI activation.

The following example shows the **uap:Extension** registering the URI scheme "myapp-copilothotkey".

XML

```
<!-- Package.appxmanifest -->
...
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"
...

<Extensions>
  ...
  <uap:Extension Category="windows.protocol">
    <uap:Protocol Name="myapp-copilothotkey"> <!-- app-defined protocol name
-->
      <uap:DisplayName>SDK Sample URI Scheme</uap:DisplayName>
    </uap:Protocol>
  </uap:Extension>
  ...
```

Microsoft Copilot hardware key app extension

An app must be packaged in order to register as a Microsoft Copilot hardware key provider. For information on app packaging, see An overview of Package Identity in Windows app. Microsoft Copilot hardware key providers declare their registration information within the uap3:AppExtension. The **Name** attribute of the extension must be set to "com.microsoft.windows.copilotkeyprovider". To support the key state changes, apps must provide some additional entries to their **uap3:AppExtension** declaration.

Inside of the **uap3:AppExtension** element, add a uap3:Properties element with child elements **PressAndHoldStart** and **PressAndHoldStop**. The contents of these elements should be the URI of the protocol scheme registered in the manifest in the previous step. The query string arguments specify whether the URI is being launched because the user pressed and held the hot key or because the user released the hot key. The app

uses these query string values during app activation to determine the correct action to take.

XML

```
<!-- Package.appxmanifest -->

<Extensions>
  ...
  <uap3:Extension Category="windows.appExtension">
    <uap3:AppExtension Name="com.microsoft.windows.copilotkeyprovider"
      Id="MyAppId"
      DisplayName="App display name"
      Description="App description"
      PublicFolder="Public">
      <uap3:Properties>
        <PressAndHoldStart>myapp-copilothotkey:?
state=Down</PressAndHoldStart>
        <PressAndHoldStop>myapp-copilothotkey:?state=Up</PressAndHoldStop>
      </uap3:Properties>
    </ uap3:AppExtension>
  </uap3:Extension>
  ...
```

Handle URI activation

To detect whether the app was activated via URI activation, call AppInstance.GetActivatedEventArgs and check to see if the value of the AppActivationArguments.Kind property is Protocol. If the app was launched via protocol activation, check to see if the URI scheme is the same as the protocol name you specified in your app manifest. If all of these tests pass, then you know that your app was activated by the user pressing the Copilot hardware key. At this point you can parse the URI query string and get the *state* parameter, which will have the values you specified in the **PressAndHoldStart** and **PressAndHoldStop** elements in the app manifest.

C#

```
// App.xaml.cs

protected override void
OnLaunched(Microsoft.UI.Xaml.LaunchActivatedEventArgs args)
{
    var eventargs = AppInstance.GetCurrent().GetActivatedEventArgs();
    string state = "";
    if ((eventargs != null) && (eventargs.Kind ==
ExtendedActivationKind.Protocol))
    {
```

```
        var protocolArgs =
(Windows.ApplicationModel.Activation.ProtocolActivatedEventArgs)eventargs.Da
ta;
        WwwFormUrlDecoder decoderEntries = new
WwwFormUrlDecoder(protocolArgs.Uri.Query);
        state =
Uri.UnescapeDataString(decoderEntries.GetFirstValueByName("state"));
    }
    state = (state == "") ? "Launched" : state;

    m_window = new MainWindow(state);
    m_window.Activate();
}
```

> **Important**
>
> Note that, by default, WinUI 3 apps are multi-instanced, which means that a new instance will be launched whenever the Microsoft Copilot hot key is pressed or released. This may be the desired behavior for many providers, but if you would prefer, you can update you app to use a single instance. For more information, see Create a single-instanced WinUI app with C#.

Handle fast path invocation

In addition to URI activation, apps can register to support fast path invocation in which a running app receives messages about Copilot hardware app through window messages. For a currently-running app, this invocation method is faster than URI activation and will provide a better user experience, since the app can begin listening for speech more quickly after the key is pressed and held.

Update the app manifest file to support fast path invocation

To add support for fast path invocation, update the "com.microsoft.windows.copilotkeyprovider" extension to add the *MessageWParam* attribute to the **SingleTap**, **PressAndHoldStart**, and **PressAndHoldStop** elements. Each *MessageWParam* value must be a unique 32-bit integer, but the values used are chosen by the app. This example uses values of 0, 1, and 2, respectively. These values will be used later in the example when they are passed in the *wParam* parameter of a Windows message to determine the current pressed state of the Windows Copilot hardware key.

```
XML
```

```
<!-- Package.appxmanifest -->

<uap3:Extension Category="windows.appExtension">
  <uap3:AppExtension Name="com.microsoft.windows.copilotkeyprovider"
    Id="MyAppId"
    DisplayName="App display name"
    Description="App description"
    PublicFolder="Public">
    <uap3:Properties>
      <SingleTap FastPathValue="0"/>
      <PressAndHoldStart MessageWParam="1">myapp-copilothotkey://?
state=Down</PressAndHoldStart>
      <PressAndHoldStop MessageWParam="2">myapp-copilothotkey://?
state=Up</PressAndHoldStop>
    </uap3:Properties>
  </uap3:AppExtension>
</uap3:Extension>
```

Access win32 APIs for window registration

Fast path activation is enabled by setting a property on the IPropertyStore associated with one of the app's windows. To do this requires access to some native Win32 APIs. This walkthrough will use the CsWin32 library, which automates the generation of C# bindings and is available as a NuGet package.

In Visual Studio, in **Solution Explorer**, right-click on your project file and select **Manage NuGet packages...**. On the **Browse** tab of the NuGet package manager, search for "cswin32" and select the "Microsoft.Windows.CsWin32" package and click *Install*.

After the package is installed, add a new text file in your project directory and name it "NativeMethods.txt". The CsWin32 tool will look in this file for a list of the Win32 APIs that it will generate bindings for. Put the following API names in "NativeMethods.txt".

`SUBCLASSPROC`

`SHGetPropertyStoreForWindow`

`IPropertyStore`

`SetWindowSubclass`

`DefSubclassProc`

Register the window for Microsoft Copilot fastpath invocation

Next we will update the **MainWindow** class to register the window to receive fastpath invocations from the Copilot hardware key.

First, call GetWindowHandle to get an HWND handle to the **MainWindow**. Call SHGetPropertyStoreForWindow to get the **IPropertyStore** for the window. Create a new PROPERTYKEY and set the *fmtid* member to the GUID for Windows Copilot fastpath activation. Set the value of the property to an app-defined value, that will be passed back to the app from the system when the hardware key state changes. The app-defined value is the windows message ID which must be in the WM_APP range. For more information, see WM_APP. Call SetValue and then call Commit to commit the change to the property store.

Finally, create a SUBCLASSPROC callback that will be called when the hardware key state changes. **WindowSubClass** is the callback implementation that will be shown in the next step. Call SetWindowSubclass to register the callback.

C#

```
private HWND hWndMain;
private Windows.Win32.UI.Shell.SUBCLASSPROC SubClassDelegate;
public const int WM_COPILOT = 0x8000 + 0x0001;

public MainWindow(string state)
{
    this.InitializeComponent();

    hWndMain = (HWND)WinRT.Interop.WindowNative.GetWindowHandle(this);
    Microsoft.UI.Windowing.AppWindow appWindow = AppWindow;

    var propertyStoreGUID = new Guid("886D8EEB-8CF2-4446-8D02-
CDBA1DBDCF99");
    var hr =
PInvoke.SHGetPropertyStoreForWindow((HWND)this.AppWindow.Id.Value, in
propertyStoreGUID, out var propertyStore);
    var key = new PROPERTYKEY();
    var copilotFastpathGUID = new Guid("38652BCA-4329-4E74-86F9-
39CF29345EEA");
    key.fmtid = copilotFastpathGUID;
    key.pid = 0x00000002;
    var value = new PROPVARIANT();
    value.Anonymous.Anonymous.vt = VARENUM.VT_UINT;
    value.Anonymous.decVal = WM_COPILOT;
    ((IPropertyStore)propertyStore).SetValue(in key, in value);
    ((IPropertyStore)propertyStore).Commit();

    SubClassDelegate = new
Windows.Win32.UI.Shell.SUBCLASSPROC(WindowSubClass);
    bool bRet = PInvoke.SetWindowSubclass((HWND)appWindow.Id.Value,
SubClassDelegate, 0, 0);
```

```
    _state = state;
}
```

Implement the window subclass callback

The last step in this example is implementing the window subclass callback that will be called whenever the app is running and the state of the Windows Copilot hardware key changes. In this example, we check that the window message is the **WM_COPILOT** value that we specified when setting the property store value in the previous step. Then we check the value of the *wParam* argument to see which of the values we specified with the **MessageWParam** attributes in the app manifest has been passed in. **SetState** is called to update the UI with the current state.

C#

```
private LRESULT WindowSubClass(HWND hWnd, uint uMsg, WPARAM wParam, LPARAM
lParam, nuint uIdSubclass, nuint dwRefData)
{
    switch (uMsg)
    {
        case WM_COPILOT:
        {
            switch (wParam.Value)
            {
                case 0:
                    SetState("SingleTap");
                    break;
                case 1:
                    SetState("PressAndHold START");
                    break;
                case 2:
                    SetState("PressAndHold END");
                    break;
            }
        }
        break;

    }
    return PInvoke.DefSubclassProc((HWND)hWnd, uMsg, wParam, lParam);

}
```

Sign your Windows Copilot hardware key provider

Provider apps must be signed in order to be enabled as a target of the Microsoft Copilot hardware key. For information on packaging and signing your app, see Package a desktop or UWP app in Visual Studio.

Cross Device People API

Article • 06/18/2024

Windows is an ideal platform for third party apps to integrate their top people contacts. This integration enables users to interact with the personas for various people experiences. Windows now provides third party WinUI 3, UWP, and other apps with package identity with APIs to store all their contacts.

> **ⓘ Important**
>
> Some information relates to a prerelease product which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.

> **ⓘ Note**
>
> Apps can try this feature as soon as it is released to the Windows Insider Program (Beta Channel) in Windows Update settings (see Get started with the Windows Insider Program for more information).

Once your apps store their contacts in Windows, users will be able to see these contact suggestions on the **Share** panel in Windows to seamlessly share with their top contacts. See How to share files in File Explorer on Windows for more information about the **Share** panel.

Creating a UserDataAccount for People Contract

Start by creating a user data account. Third party apps are required to create a UserDataAccount with `UserDisplayName` as `"com.microsoft.peoplecontract"`.

C#

```
UserDataAccountStore udas =
    await
UserDataAccountManager.RequestStoreAsync(UserDataAccountStoreAccessType.AppA
ccountsReadWrite);
UserDataAccount uda = await
udas.CreateAccountAsync("com.microsoft.peoplecontract");
```

Next, add `"com.microsoft.windows.system"` to the list of ExplictReadAccessPackageFamilyNames for the account. This will provide restricted access of third party contacts to Windows experiences.

C#

```
uda.ExplictReadAccessPackageFamilyNames.Add("com.microsoft.windows.system");
await uda.SaveAsync();
```

Storing contacts

The first step in storing contacts is to create a contact list. To do this, third party apps must create the new contact list for a `UserDataAccount` in the Windows ContactStore. Apps can choose to keep the default `OtherAppReadAccess` access type for the contact list, while setting it to `None` will prevent other apps from having any access to these contacts. See the ContactListOtherAppReadAccess enum for the full list of available access types.

C#

```
ContactStore store = await
ContactManager.RequestStoreAsync(ContactStoreAccessType.AppContactsReadWrite
);
this.contactList = await store.CreateContactListAsync(contactListsName,
uda.Id);
contactList.OtherAppReadAccess = ContactListOtherAppReadAccess.None;
await contactList.SaveAsync();
```

While storing a contact, third party apps must include all relevant information required for Windows experiences to power a Contact.

The following fields are required when storing a contact:

- `FirstName`
- `RemoteId`
- `DisplayPicture`

The following fields are optional:

- `LastName`
- `Phones`
- `Emails`

This code snippet demonstrates how to store a contact:

```
C#
```

```
foreach (var appContact in AppContacts)
{
  var cont = new Contact
  {
    FirstName = appContact.FirstName,
    LastName = appContact.LastName,
    RemoteId = appContact.Id,
    SourceDisplayPicture = RandomAccessStreamReference.CreateFromUri(new
Uri(appContact.ProfilePicPath)),
    Phones = { new ContactPhone { Number = appContact.Phone } }
  };

  await this.contactList.SaveContactAsync(cont);
}
```

> **Note**
>
> The `DisplayName` for the **Contact** is constructed using `FirstName` and `LastName`. If the last name is not provided, `DisplayName` will be identical to the string provided for the first name.

Storing ranks for contacts

You can create an annotation list for the `UserDataAccount` to store ranks for your contacts. Apps can store ranks for their top contacts by adding annotations to the contacts. These annotations are stored as part of an annotation list in the contact store.

```
C#
```

```
ContactAnnotationStore annotationStore = await

ContactManager.RequestAnnotationStoreAsync(ContactAnnotationStoreAccessType.
AppAnnotationsReadWrite);
this.contactAnnotationList = await
annotationStore.CreateAnnotationListAsync(uda.Id);
```

You can store ranks for your top contacts by using the annotations on contacts. Ranks are stored as part of ProviderProperties on a contact annotation. Along with rank, apps must set the SupportedOperations on a contact annotation as `Share`.

```
C#
```

```
foreach (var appContact in topAppContacts)
{
  Contact contact = await
list.GetContactFromRemoteIdAsync(topAppContact.RemoteID);
  var annotation = new ContactAnnotation
  {
    ContactId = contact.Id,
    SupportedOperations = ContactAnnotationOperations.Share
  };
  annotation.ProviderProperties.Add("Rank", rank);
  await annotationsLst.TrySaveAnnotationAsync(annotation);
}
```

Updating contact ranks

It's at the discretion of apps when to update the ranks of the contacts stored in Windows. Windows recommends that ranked lists be updated regularly to provide the best user experience. Whenever you need to update a ranked list, you'll need to follow several steps.

1. Delete the ContactAnnotationList.

   Once the app has an updated list of top contacts, the annotation list can be deleted and a new annotation list with updated annotations for their top contacts can be created.

   C#

   ```
   await this.contactAnnotationList.DeleteAsync();
   ```

2. Create a new `ContactAnnotationList`. Follow the steps in the Storing ranks for contacts section to create a new annotation list and store ranks for your top contacts.

Smart App Control

Article • 12/15/2022

Smart App Control is a new app execution control feature that combines Microsoft's app intelligence services and Windows' code integrity features to protect users from untrusted or potentially dangerous code. Smart App Control selectively allows apps and binaries to run only if they're likely to be safe. Microsoft's app intelligence services provide safety predictions for many popular apps. If the app intelligence service is unable to make a prediction, then Smart App Control will still allow an app to run if it is signed with a certificate issued by a certificate authority (CA) within the Trusted Root Program.

Malware, Potentially Unwanted Apps (PUA), and unknown, unsigned code are blocked by default.

Smart App Control requirements

Smart App Control is designed to protect a device for its entire lifetime. As such, it can only be enabled on a clean install of a version of Windows that contains the Smart App Control feature. Additionally, Smart App Control is only enabled in certain regions. We hope to roll out additional regions soon.

- Windows 11, version 22572 or higher,
- A clean Windows install,

  > **Note**
  >
  > **Resetting your device** counts as a clean Windows install.

- North America or Europe

Smart App Control stages

Smart App Control can be running in either *evaluation mode* or *enforcement mode*.

In *evaluation mode*, Smart App Control runs in the background, observing activity on the device. During this time, Smart App Control is evaluating whether the device is a good fit for the protection it offers based the variety of apps installed and used on the device.

In *enforcement mode*, Smart App Control is actively protecting your device. Apps cannot be run unless they are recognized by Microsoft's app intelligence services, or signed

with a trusted certificate.

Frequently Asked Questions

How can I tell if Smart App Control is installed my device?

Go to **Settings** > **Windows Security** > **App and Browser Control**. If Smart App Control is installed on your system, you will see a section called **Smart App Control**

How can I tell if Smart App Control running in evaluation or enforcement mode?

Go to **Settings** > **Windows Security** > **App and Browser Control**.

- If **On** is selected, Smart App Control is running in enforcement mode.
- If **Evaluation** is selected, Smart App Control is running in evaluation mode.
- If **Off** is selected, Smart App Control is not running on this device.

Will I be notified when Smart App Control enters enforcement mode?

Yes. You will receive a Toast Notification when Smart App Control enters enforcement mode.

What files will Smart App Control block while running in enforcement mode?

Smart App Control allows apps and binaries to run only if they're likely to be safe. Smart App Control will block apps and binary files identified as unsafe by Microsoft's app intelligence services unless those files are code signed with a certificate issued by a certificate authority (CA) within the Trusted Root Program.

Note that some older Microsoft binaries are considered unsafe because attackers can potentially use them to gain unauthorized access. For a complete list of these files, please see Application Control for Windows.

Further information

- What is Smart App Control?

Sign your app for Smart App Control compliance

Article • 05/09/2024

Code signing is a cryptographic operation that can be performed on an app in order to verify its contents and publisher. Smart App Control considers apps signed with a trusted digital certificate to be safe, and allows them to run on a protected computer.

There are several ways to sign your app.

Obtain a code signing certificate from a trusted provider

Code can be signed with any certificate, but Smart App Control only considers certificates issued by trusted providers. For information about how to obtain a code signing certificate from a trusted provider, see Manage code signing certificates

Sign your app with Trusted Signing

Trusted Signing (formerly Azure Code Signing) is the preferred way to sign your app. Trusted Signing is currently in public preview.

Sign your app with signtool.exe

Signtool.exe is an app included with Visual Studio that can sign apps with a digital certificate. For instructions on how to sign your app with signtool.exe, see How to sign an app package using SignTool

Test your app's signature with Smart App Control

Article • 12/15/2022

Before distributing your signed app to users, you should test your app's signature against Smart App Control. Because Smart App Control evaluates binaries as they're loaded, be sure to test all code paths and features of your app. This includes testing all of your app's install and uninstall binaries, all of your app's features, and all integrations with other apps that might load your binaries (for example, Office add-ins). You can test Smart App Control using audit policies, which will create log entries without actually blocking your app from executing, or test directly against Smart App Control's enforcement mode.

Configure Smart App Control for Testing

You can configure Smart App Control in the Windows Settings app, or by manually editing the Windows Registry.

Configure Smart App Control using Windows Settings

Go to **Settings** > **Privacy & Security** > **Windows Security** > **App and Browser Control** > **Smart App Control settings**.

> **Note**
>
> Configuring Smart App Control to **Off** or **On** (enforcement) is a one-way operation. This means you cannot change modes using Windows Settings unless the current setting is **Evaluation**. For testing purposes, you can force Smart App Control into another setting **using the registry**.

If Smart App Control is in Evaluation mode, Smart App Control will evaluate your app's signature, but will not block your app if its signature is invalid. In this mode, you can use Audit Policies to view Smart App Control's output, including errors encountered while checking your app's signature.

Select **On** to put Smart App Control in enforcement mode. In this mode, Smart App Control will prevent your app from running if its signature is invalid.

Configure Smart App Control using the Registry

> **ⓘ Important**
>
> Smart App Control can be manually configured via the Registry **for testing purposes only.** Editing Smart App Control settings in this way could compromise the protection it provides.

Configuring Smart App Control using the Windows Registry allows you to force any desired enforcement mode, even if you cannot select that mode using Windows Settings. To configure Smart App Control:

1. Open a command prompt with administrator privileges and execute the following commands:

   ```PowerShell
   manage-bde -protectors c: -disable -rebootcount 2
   "C:\Program Files\Windows Defender\MpCmdRun.exe" -RemoveDefinitions -DynamicSignatures
   ```

   > **ⓘ Note**
   >
   > You may have to update the second command if your system drive is not C:.

2. Reboot into the boot menu by launching Settings and selecting **Recovery** > **Recovery Options** > **Advanced Startup** > **Restart now**.

3. From the advanced boot menu, select **Troubleshoot** > **Advanced** > **Command Prompt**. A recovery command prompt will open.

   > **ⓘ Note**
   >
   > The recovery command prompt opens the recovery drive X: by default. This does not indicate your system drive has changed. Your system drive is still associated with its usual drive letter (usually C:).

4. Execute the following commands:

   > **ⓘ Note**

In the following commands, replace {VALUE} with the value of the mode you want to set.

Value	Mode
0	Off
1	On (Enforcement)
2	Evaluation

ps

```
reg load HKLM\sac c:\windows\system32\config\system
reg add hklm\sac\controlset001\control\ci\policy /v
VerifiedAndReputablePolicyState /t REG_DWORD /d {VALUE} /f
reg add hklm\sac\controlset001\control\ci\protected /v
VerifiedAndReputablePolicyStateMinValueSeen /t REG_DWORD /d {VALUE} /f
reg unload hklm\sac

reg load HKLM\sac2 C:\windows\system32\config\SOFTWARE
reg add "hklm\sac2\Microsoft\Windows Defender" /v SacLearningModeSwitch
/t REG_DWORD /d 0
reg unload hklm\sac2
```

5. Restart the computer.

Verify Smart App Control's current mode

You can verify Smart App Control's current mode by opening a command prompt and executing the following command:

`citool.exe -lp`

Smart App Control is in evaluation mode if the value of Friendly Name is `VerifiedAndReputableDesktopEvaluation` and the value of Is Currently Enforced is `true`.

Smart App Control is in enforcement mode if the value of Friendly Name is `VerifiedAndReputableDesktop` and the value of Is Currently Enforced is `true`.

Configure Smart App Control's audit policy

The default Windows Defender Application Control (WDAC) policy used by Smart App Control in evaluation mode does not log audit events in the CodeIntegrity Operational log. This is to reduce the size of the log on typical consumer devices shipping with Smart App Control in evaluation mode.

For the purposes of evaluating applications against Smart App Control, a developer or system administrator may want to enable audit logs in evaluation mode to see what files would be blocked if the system were in enforcement mode.

> **Note**
>
> Audit policies only apply when Smart App Control is running in Evaluation mode. In Enforcement mode, Smart App Control will log events by default.

A zip file containing two sample policies below can be downloaded here.

> **Note**
>
> You can also create your own policies. See **Windows Defender Application Control (WDAC) example base policies** and **Create WDAC policy for lightly managed devices** for more information.

Smart App Control audit policy (SmartAppControlAudit.bin)

This is the standard Smart App Control policy, with audit logs enabled in evaluation mode. All binaries and scripts allowed by signature and cloud reputation will pass the policy, just as they would if enforcement mode was enabled. Applications and binaries that would be blocked would log an audit event.

> **Note**
>
> This policy only works with Smart App Control in evaluation mode. It is still possible for the Smart App Control evaluation model to turn evaluation mode off with this policy is applied, so we recommend testing with one of the other methods below.

When this policy is applied, the output for `citool.exe -lp` will show `VerifiedAndReputableDesktopEvaluationAudit` as the policy name.

Apply the Smart App Control audit policy

First, ensure SAC is in evaluation mode.

Take ownership of the evaluation mode policy file `C:\WINDOWS\System32\CodeIntegrity\CiPolicies\Active\{1283AC0F-FFF1-49AE-ADA1-8A933130CAD6}.cip` using takeown.exe. If you are unable to use takeown, then you can manually take ownership using the following steps:

> **ⓘ Important**
>
> We strongly recommend using takeown, if possible.

1. Right click the file in explorer and select "Properties."
2. Go to the Security tab, and choose Advanced at the bottom.
3. Click "Change" in the dialog.
4. In the popup dialog, enter your user information (e.g. `<PC name>\<username>`) and click OK.
5. Click OK in the Advanced Security Settings dialog and confirm.
6. Reopen the file properties Security tab and click "Edit."
7. Under Administrators, choose all the checkboxes and click OK, and confirm again in the popup dialog.

Now that you have ownership of the policy file, rename it to `{1283AC0F-FFF1-49AE-ADA1-8A933130CAD6}.cip.old`. Rename the audit policy file you want to apply to `{1283AC0F-FFF1-49AE-ADA1-8A933130CAD6}.cip`, and copy it to the policy directory.

Run `citool.exe -r` from an admin command prompt to refresh the policy.

Smart App Control audit policy without ISG (SmartAppControlAuditNoISG.bin)

This is the recommended policy for testing your own apps as a developer.

This policy checks binaries and scripts against Smart App Control in evaluation mode, without checking the Intelligent Security Graph, meaning that only apps that are properly signed by a trusted certificate will be allowed without audit events. Because reputation may not be available for newly published binaries, and can change over time, ensuring that all your binaries are correctly signed is the best way to make sure users don't encounter issues using your app. This is also the requirement when publishing

through the Windows Store, where a signature from a cert obtained from a trusted Certificate Authority is required.

This policy can be applied even when Smart App Control is set to Off. When this policy is applied, the output for `citool.exe -lp` will show `VerifiedAndReputableDesktopEvaluationAuditNoISG` as the policy name.

Apply the Smart App Control Audit policy without ISG

This policy is for testing applications in evaluation mode against the signing requirement of Smart App Control exclusively, and will not allow any app binaries based on cloud intelligence from the Intelligent Security Graph.

Ensure that Smart App Control is in evaluation mode or off

Run `mountvol S: /S` from an admin command prompt

copy SmartAppControlAuditNoISG.bin to `S:\efi\microsoft\boot\cipolicies\active\{5283AC0F-FFF1-49AE-ADA1-8A933130CAD6}.cip` .

Run `citool.exe -r` from admin command line to refresh the policy

Checking Event Logs

Smart App Control logs any executable that was (or would have been) blocked into the Code Integrity Event Logs. You can find those logs by opening the Event Viewer, and then browsing to **Application and Services Logs** > **Microsoft** > **Windows** > **CodeIntegrity** > **Operational**.

Smart App Control logs evaluation mode events with event ID 3076, and enforcement mode events with event ID 3077. For more information about Smart App Control and Microsoft Defender event logging, please see Review event logs and error codes to troubleshoot issues with Microsoft Defender Antivirus.

Integrate with Windows Search

Article • 05/10/2025

This section of the documentation provides developer guidance for integrating with Windows Search.

Windows system components that support 3rd party integration

The following table lists the Windows Search integration features for 3rd party developers.

Cloud files provider integration with Windows Search	Learn about cloud file provider integration with Windows Search.

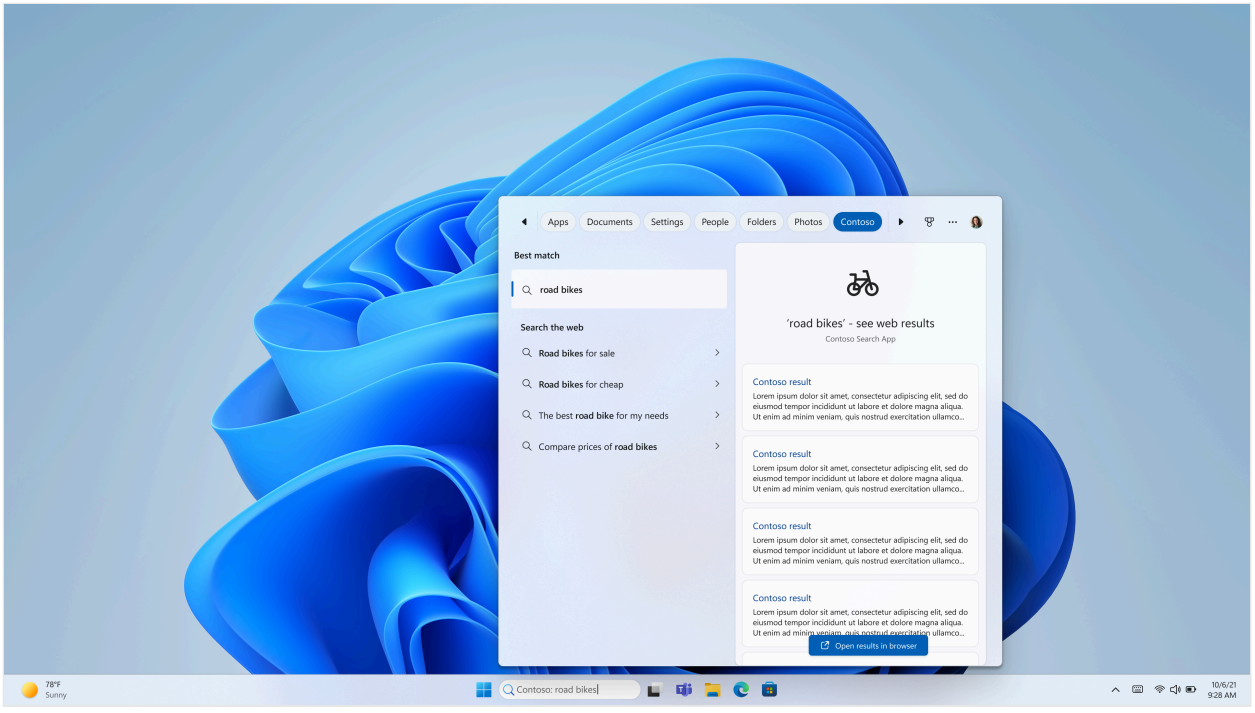
Windows Search providers

Article • 05/07/2024

> **Note**
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

> **Important**
>
> The feature described in this topic is available in preview builds of Windows starting with build 22631.2787 for Windows 11 and build 19045.3758 for Windows 10, although newer builds are recommended because they contain stability improvements. For information on preview builds of Windows, see Windows 10 Insider Preview.

Windows Search currently uses the Web Search from Microsoft Bing app to return web content and search results. In the European Economic Area (EEA), you can enable installed apps that implement a web search provider to return web content and search results in Windows Search through Settings.



Search providers integrate with the Search experience by creating an MSIX package with a package manifest file that provides the required information for the OS to register the

search provider. Users can add a search provider to Windows by installing the associated app package and can remove the search provider through the **Add or remove programs** page in Windows Settings app.

For development and testing, when Developer Mode is enabled and the search provider app has been sideloaded on the device, it will appear in the list of available search providers. For more information, see Developer Mode features and debugging.

Once the search provider is registered with the OS, user queries are passed to the HTTP endpoint specified by the provider in their package manifest using a standardized query string. The endpoint returns suggested results in a JSON document. With each suggested URL in the response document, the search provider includes the preview endpoint URL, which returns an HTML document that is displayed in the preview pane in the search results UI.

This article provides guidance for creating a search provider app package and details about the protocols for implementing search provider HTTP endpoints.

Create a search extensibility app package

Search providers register with the OS by providing an MSIX package that contains required information about the provider, such as the name of the search provider and the HTTP endpoints for suggestions and previews.

Search provider app extension

The app package manifest file supports many different extensions and features for Windows apps. The app package manifest format is defined by a set of schemas that are documented in the Package manifest schema reference. Search providers declare their registration information within the uap3:AppExtension. The **Name** attribute of the extension must be set to "com.microsoft.windows.websearchprovider".

Search providers should include the uap3:Properties as the child of **uap3:AppExtension**. The package manifest schema does not enforce the structure of the **uap3:Properties** element other than requiring well-formed XML. The rest of this section describes the XML format that the OS expects in order to successfully register a search provider.

XML

```
<uap3:Extension Category="windows.appExtension">
  <uap3:AppExtension Name="com.microsoft.windows.websearchprovider"
DisplayName="SearchExampleApp" Id="ContosoSearchApp" PublicFolder="Public">
    <uap3:Properties>
```

```
    <!-- Search provider registration content goes here -->
    </uap3:Properties>
  </uap3:AppExtension>
</uap3:Extension>
```

Element hierarchy

uap3:Properties

EndPoint

Protocol

Endpoint

The URL of the HTTPS endpoint to which the OS will send search query requests.

Protocol

The protocol schema that will be used when launching the provided web search results. If the specified protocol is not registered by an app on the OS, then the default browser will be launched for search results. For more information on registering protocol schemas, see uap:Protocol.

DynamicContentEndpoint

The URL of the HTTPS endpoint to which the OS will send a request for the gleam icon to be displayed in the search box. For more information see Implement a gleam icon endpoint. This feature is supported starting with Windows 10 build 19045.4233 and Windows 11 build 22621.3371.

Example package manifest file

The following is an example `appmanifest.xml` package manifest file for registering a Windows Search provider.

XML

```
<!-- appxmanifest.xml -->

  <uap3:Extension Category="windows.appExtension">
      <uap3:AppExtension Name="com.microsoft.windows.websearchprovider"
DisplayName="CustomSearch" Id="CustomSearchApp" PublicFolder="Public">
```

```
            <uap3:Properties>
                <Endpoint>https://customsearchendpoint</Endpoint>
                <Protocol>customsearch</Protocol>

<DynamicContentEndpoint>https://sub.contoso.com/dynamic</DynamicContentEndpo
int>
            </uap3:Properties>
        </uap3:AppExtension>
    </uap3:Extension>
    <uap:Extension Category="windows.protocol">
        <uap:Protocol Name="customsearch"/>
    </uap:Extension>
```

Implement a Windows Search provider suggestion endpoint

Search providers must expose and register an HTTPS endpoint that is called by the OS when a user types into the Windows Search box. This endpoint should return a JSON-formatted string containing the search suggestions for the provided user query. Content must be delivered over HTTPS. Search integration does not support content delivered over HTTP.

Suggestion HTTPS request format

The HTTPS request to the suggestion endpoint uses the following format.

`https://contoso.com?setlang=en-US&cc=US&qry=`

The query string parameters passed to the suggestion endpoint are the following.

Expand table

Parameter	Description
setlang	The locale associated with the query.
cc	The country code associated with query.
qry	The query provided by the user. If the parameter has no value, i.e. appears in the query string as `qry=`, then the user query is empty. Search providers can still provide suggestions and preview pages in response to an empty query. **NOTE** The OS does not perform any sanitization of query strings. Search providers can implement their own sanitization when the query is received.

Suggestion HTTPS response headers

Search provider must include the following headers in the response from the suggestion HTTPS endpoint.

- Access-Control-Allow-Origin: https://www.bing.com
- Access-Control-Allow-Credentials: true
- Access-Control-Allow-Methods: GET
- Content-Type: application/json; charset=utf-8
- Content-Length: [Must be the exact length of response]

Suggestion response JSON format

The search provider HTTPS endpoint for suggestions must return a JSON document with the following format. The key names must match the format exactly.

Expand table

Key	Description
Suggestions	Contains a list of JSON objects with key `Attributes` representing the suggestions associated with the user query.
Attributes	Contains the attributes of a suggestion.
url	The URL for the search suggestion on the provider web site.
query	The user query associated with the search suggestion.
previewPaneUrl	The URL of the preview endpoint from which an HTML preview of the suggestion can be retrieved.
Text	The text description of the suggestion.

JSON

```
{"Suggestions":
   [{"Attributes":
     {"url":"https://www.contoso.com/search?
q=projection+matrix","query":"projection
matrix","previewPaneUrl":"http://www.contoso.com/preview"}
,"Text":"projection matrix"},
    {"Attributes":
     {"url":"https://www.contoso.com/search?
q=rotation+matrix","query":"rotation
matrix","previewPaneUrl":"http://www.contoso.com/preview"} ,"Text":"rotation
matrix"}
```

```
    ]
}
```

Implement a Windows Search provider preview endpoint

Search providers return the URL of an HTTPS endpoint that provides an HTML preview of the page associated with each suggestion in the search results. The preview endpoint response must return the HTML code for a functioning page.

Preview HTTPS request format

The HTTPS request to the preview endpoint uses the following format.

`https://contoso.com?Darkschemeovr=1`

The query string parameters passed to the suggestion endpoint are the following.

Expand table

Parameter	Description
Darkschemeovr	Specifies if the calling Windows system has dark theme enabled. The value is 1 if dark theme is enabled and 0 if the dark theme is disabled.

Preview HTTPS response headers

- Access-Control-Allow-Origin: https://www.bing.com
- Access-Control-Allow-Credentials: true
- Access-Control-Allow-Methods: GET
- Content-Type: text/html; charset=utf-8
- Content-Length: [Must be the exact length of preview html]

OPTIONS request and Cross-Origin Resource Sharing (CORS)

Search providers must support the OPTIONS request method and respond to this request with HTTP OK. If the search provider endpoint is using CORS, the Windows search client will send out a HTTP OPTIONS request before each GET request.

Implement a gleam icon endpoint

Search providers can optionally provide light and dark mode gleam icons that are displayed in the search bar when the search provider is currently enabled. When the **DynamicContentEndpoint** element is provided in the app manifest, a request will be sent to the specified URL and the search provider responds with a json file in the format defined below that includes the URLs of the icon image files and other metadata. The gleam icon request will be sent periodically while the search provider is the most recent provider active in Windows Search. The cadence for this request is every 6 hours. A request will also be sent upon each Search launch and on device unlock.

Gleam icon HTTPS request format

The HTTPS request to the gleam icon endpoint uses the following format.

```
https://www.contoso.com/Gleam?cc=FR&setlang=en-us&dateTime=3%2F29%2F2024%2C%208%3A33%3A56%20PM&deviceOs=windows10&schemaversion=1.0.0
```

The query string parameters passed to the suggestion endpoint are the following.

Expand table

Parameter	Description
setlang	The locale associated with the query.
cc	The country code associated with query.
dateTime	The current date and time from client device, url-encoded.
deviceOs	The OS of the client device. The value of this parameter can be "Windows10" or "Windows11". On Windows 10, the gleam icon size is 30x60. On Windows 11, the gleam icon size is 20x36
schemaversion	The gleam schema version.

Gleam icon response JSON format

The search provider HTTPS endpoint for gleam icons must return a JSON document with the following format. The key names must match the format exactly. The current schema version is 1.0.0.

Expand table

Key	Description
schemaVersion	The gleam schema version. This should match the *schemaVersion* query string parameter in the request.
telemetryId	A unique identifier for the gleam icon. If the value in the response is the same as the value for the current gleam icon, the OS will not update the icon.
expirationTime	The expiration time for the gleam icon. Must be a time in the future.
content	The content section of the response.
taskbarSearchBox	Contains settings for the search box.
gleam	Contains settings for the gleam icon.
altText	Alternate text for the gleam icon.
dimensionEnum	The value "30x60" if the request was sent from a Windows 10 device. The value "20x36" if the request was sent from a Windows 11 device.
iconUrl	Contains the URLs for the light and dark gleam icon image files.
light	The URL for the light gleam icon image file.
dark	The URL for the dark gleam icon image file.

JSON

```
{
  "schemaVersion":"1.0.0",
  "telemetryId":"<unique gleam Id>",
  "expirationTime":"2025-12-09T20:37:13Z",
  "content": {
    "taskbarSearchBox": {
      "gleam":{
        "altText": "<alt text of the gleam>",
        "dimensionEnum": "(30x60 for Windows 10, 20x36 for Windows 11)",
        "iconUrl": {
          "light":"<3p's light gleam url>",
          "dark": "<3p's dark gleam url>"
        }
      }
    }
  }
}
```

Gleam icon response validation

The response must specify both the light asset URL and the dark asset URL. The domains for the icon image URLs must use HTTPS and the subdomain must match the subdomain specified in the **DynamicContentEndpoint** element in the app manifest file.

The image files must be in SVG format and the maximum file size is 300 kB. The gleam needs to be within a 240x120px frame inside the SVG.

If an empty payload is received, that will clear the active gleam icon and no gleam will be displayed.

Integrate Share options in your Windows app: A comprehensive guide

Article • 11/11/2024

The Windows Share Sheet is a system-provided UI that enables users to share content from your app with other Windows apps. The Share Sheet is available in the Windows shell and is accessible from any app that supports sharing. It provides a consistent and familiar experience for users, and it's a great way to increase the discoverability of your app.

Integrating share options in your Windows app can significantly enhance user experience by allowing seamless content sharing across different applications. Whether you're developing a new app or updating an existing one, this guide will provide you with the necessary steps and code samples to implement the Windows Share feature effectively.

In this comprehensive guide, you'll learn how to add the share feature to your packaged or unpackaged Windows app, implement file sharing methods, and show your app on the share sheet. You can leverage share options in a .NET, Windows C++, or PWA app, and this guide will help you get started. By following these steps, you can ensure that your app leverages the full potential of the Windows Share feature, making it more interactive and user-friendly.

Integrate packaged apps with Windows Share

Article • 05/08/2024

This article explains how to integrate packaged apps with the **Windows Share** feature. Apps that are packaged with MSIX have package identity and are ready to register as a **Share Target**. The Share feature allows users to share content from one app to another. A packaged app will register as a Share Target in order to receive and handle shared files within the app.

What is Share Target?

Share Target is a feature that was introduced in Windows 8, and it allows an app to receive data from another app. Share Target works like a Clipboard but with dynamic content.

For the default share target registration to work with Win32 apps, the app needs to have a package identity and also handle the share arguments as ShareTargetActivatedEventArgs, which is a live object from the source app. It isn't a static memory content that is sent to the target app.

> ⓘ **Note**
>
> In a C++ app, use the GetCurrentPackageFullName API to check if the running app has package identity. The API returns the `APPMODEL_ERROR_NO_PACKAGE` error code if it isn't running with package identity.

Prerequisites

To support `ShareTargetActivatedEventArgs`, the app must target Windows 10, version 2004 (build 10.0.19041.0) or later. This is the minimum target version for the feature.

Register as a Share Target

There are two steps required to implement the Share contract in your app.

Add a share target extension to appxmanifest

In Visual Studio's Solution Explorer, open the `package.appxmanifest` file of the Packaging project in your solution and add the share target extension.

XML

```
<Extensions>
      <uap:Extension
          Category="windows.shareTarget">
        <uap:ShareTarget>
          <uap:SupportedFileTypes>
            <uap:SupportsAnyFileType />
          </uap:SupportedFileTypes>
          <uap:DataFormat>Bitmap</uap:DataFormat>
        </uap:ShareTarget>
      </uap:Extension>
</Extensions>
```

Add the supported data format that is supported by your application to the `DataFormat` configuration. In this case, the app supports sharing images, so the `DataFormat` is set to `Bitmap`.

Fetch Share Event arguments

Starting in Windows 10, version 1809, packaged apps can call the AppInstance.GetActivatedEventArgs method to retrieve certain kinds of app activation info during startup. For example, you can call this method to get information about app activation; whether it was triggered by opening a file, clicking an interactive toast, or using a registered protocol.

However, ShareTargetActivatedEventArgs activation info is supported only on Windows 10, version 2004, and later. So, the application should target to devices with this specific minimum version.

To see a Windows App SDK implementation, see the `OnLaunched` method in the Share Target sample app.

For other packaged apps, in the `Main` method of the application, check for `AppInstance.GetActivatedEventArgs`.

C#

```
public static void Main(string[] cmdArgs)
{
    ...
    if (isRunningWithIdentity())
    {
```

```
        var activationArgs = AppInstance.GetActivatedEventArgs();
        if (activationArgs != null)
        {
            switch (activationArgs.Kind)
            {
                case ActivationKind.Launch:
                    HandleLaunch(activationArgs as
LaunchActivatedEventArgs);
                    break;
                case ActivationKind.ToastNotification:
                    HandleToastNotification(activationArgs as
ToastNotificationActivatedEventArgs);
                    break;
                case ActivationKind.ShareTarget:
                    HandleShareAsync(activationArgs as
ShareTargetActivatedEventArgs);
                    break;
                default:
                    HandleLaunch(null);
                    break;
            }
        }
    }
}
```

See the Photo Store Demo app for a complete implementation.

Handle shared files

The following code snippet shows how to handle shared files in a packaged app. The code snippet is part of the `HandleShareAsync` method that is called when the app is activated as a Share Target in the previous example.

C#

```
static async void HandleShareAsync(ShareTargetActivatedEventArgs args)
{
    ShareOperation shareOperation = args.ShareOperation;
    shareOperation.ReportStarted();

    if (shareOperation.Data.Contains(

Windows.ApplicationModel.DataTransfer.StandardDataFormats.StorageItems))
    {
        try
        {
            IReadOnlyList<IStorageItem> items = await
shareOperation.Data.GetStorageItemsAsync();
            var file = (IStorageFile)items[0];
            string path = file.Path;
            var image = new ImageFile(path);
```

```
                image.AddToCache();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.Message);
            }
        }
        shareOperation.ReportCompleted();

        // app launch code
    }
```

Integrate Progressive Web Apps with Windows Share

Article • 05/08/2024

This article explains how to integrate a Progressive Web App (PWA) with the **Windows Share** feature. This feature allows users to share content from one Windows app to another. The PWA registers as a **Share Target** to receive and handle shared files within the app.

What is Share Target?

Share Target is a feature that was introduced in Windows 8, and it allows an app to receive data from another app. Share Target works like a Clipboard but with dynamic content.

Share content from your PWA

To share content, a PWA generates content (such as text, links, or files) and hands off the shared content to the operating system. The operating system lets the user decide which app they want to use to receive that content. PWAs can use the Web Share API to trigger displaying the Share Sheet in Windows. The Web Share API is supported in Microsoft Edge and other Chromium-based browsers.

See Sharing content in the Microsoft Edge documentation for a complete example of how to share content from a PWA.

Receive shared files in your PWA

To receive content, a PWA acts as a content target. The PWA must be registered with the operating system as a content-sharing target.

The `share_target` member must contain the necessary information for the system to pass the shared content to your app. Consider the following sample manifest `share_target` configuration:

JSON

```
"share_target": {
  "action": "./share_target_path/?custom_param=foo",
  "method": "POST",
```

```
  "enctype": "multipart/form-data",
  "params": {
    "files": [
      {
        "name": "mapped_files",
        "accept": ["image/jpeg"]
      }
    ]
  }
},
```

When your app is selected by the user as the target for shared content, the PWA is launched. A `GET` HTTP request is made to the URL specified by the `action` property. The shared data is passed as the `title`, `text`, and `url` query parameters. The following request is made: `/handle-shared-content/?title=shared title&text=shared text&url=shared url`.

The following example illustrates how to register the scoped service worker:

JavaScript

```
navigator.serviceWorker.register('scoped-service-worker.js',
                { scope: "./share_target_path/" })
```

The service worker handles the share data as desired, and then either fulfills the request, or it can redirect the request back out of the custom path. The following example illustrates how to redirect the request back out of the custom path:

JavaScript

```
self.addEventListener('fetch', (event) => {
    event.respondWith((async () => {
        // Read the shared data here, then
        // Redirect back out of the share_target_path to the actual site
        return
Response.redirect(event.request.url.replace("share_target_path/", ""));
    })());
    return;
});
```

See the Receiving shared content example in the Microsoft Edge documentation for more information.

Performance considerations

If the fetch handler is added solely for share support, potential latency issues may arise as the requests get interrupted by the service worker. To address this issue, consider setting the `share_target` as a pseudo sub-path and registering a service worker specifically scoped to that path. This approach enables the use of a *fetch* handler for the share target without registering the same *fetch* handler for other calls.

Sample PWA app

The PWA logo printer sample app on GitHub demonstrates how to integrate a PWA with the Windows Share Sheet. The app allows users to print the PWA logo to a printer. The app uses the Windows Share Sheet to share the logo with other apps.

Share data

Article • 10/18/2023

This article explains how to support the Share contract in a desktop or a Universal Windows Platform (UWP) app. The Share contract is an easy way to quickly share data—such as text, links, photos, and videos—between apps. For example, a user might want to share a webpage with their friends using a social networking app, or save a link in a notes app to refer to later.

> **Note**
>
> The code examples in this article are from UWP apps. Desktop apps should use the **IDataTransferManagerInterop**. For more info, and code examples, see **Display WinRT UI objects that depend on CoreWindow**. Also see the **WPF Sharing content source app sample**.

Set up an event handler

Add a **DataRequested** event handler to be called whenever a user invokes share. This can occur either when the user taps a control in your app (such as a button or app bar command) or automatically in a specific scenario (if the user finishes a level and gets a high score, for example).

C#

```
DataTransferManager dataTransferManager =
DataTransferManager.GetForCurrentView();
dataTransferManager.DataRequested += DataTransferManager_DataRequested;
```

When a **DataRequested** event occurs, your app receives a **DataRequest** object. This contains a **DataPackage** that you can use to provide the content that the user wants to share. You must provide a title and data to share. A description is optional, but recommended.

C#

```
DataRequest request = args.Request;
```

Choose data

You can share various types of data, including:

- Plain text
- Uniform Resource Identifiers (URIs)
- HTML
- Formatted text
- Bitmaps
- Files
- Custom developer-defined data

The DataPackage object can contain one or more of these formats, in any combination. The following example demonstrates sharing text.

C#

```
request.Data.SetText("Hello world!");
```

Set properties

When you package data for sharing, you can supply a variety of properties that provide additional information about the content being shared. These properties help target apps improve the user experience. For example, a description helps when the user is sharing content with more than one app. Adding a thumbnail when sharing an image or a link to a web page provides a visual reference to the user. For more information, see DataPackagePropertySet.

> ⚠ **Warning**
>
> All properties except the title are optional. The title property is mandatory and must be set.

C#

```
request.Data.Properties.Title = "Share Example";
request.Data.Properties.Description = "A demonstration on how to share";
```

Launch the share UI

A UI for sharing is provided by the system. To launch it, call the ShowShareUI method.

C#

```
DataTransferManager.ShowShareUI();
```

Handle errors

In most cases, sharing content is a straightforward process. However, there's always a chance that something unexpected could happen. For example, the app might require the user to select content for sharing but the user didn't select any. To handle these situations, use the **FailWithDisplayText** method, which will display a message to the user if something goes wrong.

Delay share with delegates

Sometimes, it might not make sense to prepare the data that the user wants to share right away. For example, if your app supports sending a large image file in several different possible formats, it's inefficient to create all those images before the user makes their selection.

To solve this problem, a **DataPackage** can contain a delegate — a function that is called when the receiving app requests data. We recommend using a delegate any time that the data a user wants to share is resource-intensive.

C#

```
async void OnDeferredImageRequestedHandler(DataProviderRequest request)
{
    // Provide updated bitmap data using delayed rendering
    if (this.imageStream != null)
    {
        DataProviderDeferral deferral = request.GetDeferral();
        InMemoryRandomAccessStream inMemoryStream = new
InMemoryRandomAccessStream();

        // Decode the image.
        BitmapDecoder imageDecoder = await
BitmapDecoder.CreateAsync(this.imageStream);

        // Re-encode the image at 50% width and height.
        BitmapEncoder imageEncoder = await
BitmapEncoder.CreateForTranscodingAsync(inMemoryStream, imageDecoder);
        imageEncoder.BitmapTransform.ScaledWidth = (uint)
(imageDecoder.OrientedPixelWidth * 0.5);
        imageEncoder.BitmapTransform.ScaledHeight = (uint)
(imageDecoder.OrientedPixelHeight * 0.5);
        await imageEncoder.FlushAsync();
```

```
request.SetData(RandomAccessStreamReference.CreateFromStream(inMemoryStream)
);
        deferral.Complete();
    }
}
```

Integrate unpackaged apps with Windows Share

Article • 05/08/2024

This article explains how to integrate unpackaged apps with the **Windows Share** feature. The Share feature allows users to share content from one Windows app to another. An unpackaged app must be provided with package identity so it can register as a **Share Target**. Once registered, the app can receive and process shared files.

How to onboard an unpackaged app as a Share Target:

- Provide the app with package identity
- Implement the Share contract

Provide unpackaged apps with package identity

An app can get package identity in two ways:

- Make a new MSIX installation package (preferred method) **OR**
- Make apps packaged with external location compatible with the current installer. This is only recommended for apps that have an existing installer and which can't switch to MSIX installation.

Make a new MSIX installation package

It's recommended to package the app with MSIX using the **Windows Application Packaging Project** template in Visual Studio. This will include all the binaries in the MSIX package and provide a clean and trusted install experience.

Things to note before packaging desktop apps: Prepare to package a desktop application (MSIX).

Follow the steps in Set up your desktop application for MSIX packaging in Visual Studio to generate a package for your existing app's project.

> **Note**

When creating the packaging project, select **Windows 10, version 2004 (10.0; Build 19041)** or later as the **Minimum version**.

When that is completed, you will create the package by following Package a desktop or UWP app in Visual Studio.

Make packaging with external location compatible with the current installer

The second way to give your app package identity is to add a package with external location to your application and register it with your existing installer. The package with external location is an empty MSIX package that contains the .appxmanifest having identity, share target registration, and visual assets. The app's binaries are still managed by app's existing installer. When registering the package, you need to provide the app's install location in the API. It is important to keep the identity in the MSIX package manifest and the Win32 app manifest in sync with the certificate used for signing the app.

Steps to grant package identity to an unpackaged app

Documentation on how to create a package with external location is available here, including information on templates to use: Grant package identity by packaging with external location.

The full sample app is available on GitHub: SparsePackages (Packaged with External Location) .

Register as a Share Target

Once the app has package identity, the next step is to implement the Share contract. The Share contract allows your app to receive data from another app.

You can follow the same steps in the Register as a Share Target section of the documentation for packaged apps to integrate with Share Sheet.

Walkthrough of the sample PhotoStore app

In this walkthrough on package identity, registration & share activation for unpackaged Win32 Applications, you will learn how to grant package identity to an unpackaged Win32 application by creating a package with external location. Once the app has

package identity, it can register and handle activation as a Share Target. You will take the following steps using the PhotoStoreDemo sample:

- Generate the `AppxManifest.xml` file
- Create a package
- Sign the package
- Register the package
- Handle app activation

Start by creating the `AppxManifest.xml` file, which includes necessary properties like `<AllowExternalContent>`, identity, and capabilities & share target extension. Make sure the `Publisher`, `PackageName` & `ApplicationId` values in the `AppxManifest.xml` file match the values in the `PhotoStoreDemo.exe.manifest` file. The `Publisher` value should also match the value in the certificate used to sign the package. Add visual assets as required and referenced in `AppxManifest.xml`. In Visual Studio, you can use the **Visual Assets** node when editing `package.manifest` in the Application Packaging project to generate required the visual assets.

This is a sample `AppxManifest.xml` snippet with external content allowed:

XML

```
<Identity Name="PhotoStoreDemo" ProcessorArchitecture="neutral"
Publisher="CN=YourPubNameHere" Version="1.0.0.0" />
  <Properties>
    <DisplayName>PhotoStoreDemo</DisplayName>
    <PublisherDisplayName>Sparse Package</PublisherDisplayName>
    <Logo>Assets\storelogo.png</Logo>
    <uap10:AllowExternalContent>true</uap10:AllowExternalContent>
  </Properties>
  <Resources>
    <Resource Language="en-us" />
  </Resources>
  <Dependencies>
    <TargetDeviceFamily Name="Windows.Desktop" MinVersion="10.0.19041.0"
MaxVersionTested="10.0.19041.0" />
  </Dependencies>
  <Capabilities>
    <rescap:Capability Name="runFullTrust" />
    <rescap:Capability Name="unvirtualizedResources"/>
  </Capabilities>
  <Applications>
    <Application Id="PhotoStoreDemo" Executable="PhotoStoreDemo.exe"
uap10:TrustLevel="mediumIL" uap10:RuntimeBehavior="win32App">
      <uap:VisualElements AppListEntry="none" DisplayName="PhotoStoreDemo"
Description="PhotoStoreDemo" BackgroundColor="transparent"
Square150x150Logo="Assets\Square150x150Logo.png"
Square44x44Logo="Assets\Square44x44Logo.png">
```

```
        <uap:DefaultTile Wide310x150Logo="Assets\Wide310x150Logo.png"
Square310x310Logo="Assets\LargeTile.png"
Square71x71Logo="Assets\SmallTile.png"></uap:DefaultTile>
        <uap:SplashScreen Image="Assets\SplashScreen.png" />
      </uap:VisualElements>
      <Extensions>
        <uap:Extension Category="windows.shareTarget">
          <uap:ShareTarget Description="Send to PhotoStoreDemo">
            <uap:SupportedFileTypes>
              <uap:FileType>.jpg</uap:FileType>
              <uap:FileType>.png</uap:FileType>
              <uap:FileType>.gif</uap:FileType>
            </uap:SupportedFileTypes>
            <uap:DataFormat>StorageItems</uap:DataFormat>
            <uap:DataFormat>Bitmap</uap:DataFormat>
          </uap:ShareTarget>
        </uap:Extension>
        ...
```

This is a sample Application.exe.manifest file:

XML

```
<?xml version="1.0" encoding="utf-8"?>
<assembly manifestVersion="1.0" xmlns="urn:schemas-microsoft-com:asm.v1">
  <assemblyIdentity version="1.0.0.0" name="PhotoStoreDemo.app"/>
  <msix xmlns="urn:schemas-microsoft-com:msix.v1"
          publisher="CN=YourPubNameHere"
          packageName="PhotoStoreDemo"
          applicationId="PhotoStoreDemo"
        />
</assembly>
```

Next, to create the package with external location, use the `MakeAppx.exe` tool with the `/nv` command to create a package containing the `AppxManifest.xml` file.

Example:

Console

```
MakeAppx.exe pack /d <Path to directory with AppxManifest.xml> /p <Output
Path>\mypackage.msix /nv
```

Note

A package with external location contains a package manifest, but no other app binaries and content. The manifest of a package with external location can reference files outside the package in a predetermined external location.

Sign your package with a trusted certificate using `SignTool.exe`.

Example:

Console

```
SignTool.exe sign /fd SHA256 /a /f <path to cert>  /p <cert key> <Path to
Package>
```

The cert used for signing the package should be installed in a trusted location on the machine.

On first run of the application, register the package with Windows. When an app has its own installer, it should also contain the signed MSIX as the payload and should place it to a specified location (for example, the app's install location). This location must be known to the app at runtime because the app will need the absolute path of MSIX to register it. Place the assets and `resources.pri` in the app's install location as well.

The following code is an example of unpackaged execution of the app's Main method:

C#

```
[STAThread]
public static void Main(string[] cmdArgs)
{
    //if app isn't running with identity, register its package with external
identity
    if (!ExecutionMode.IsRunningWithIdentity())
    {
        //TODO - update the value of externalLocation to match the output
location of your VS Build binaries and the value of
        //externalPkgPath to match the path to your signed package with
external identity (.msix).
        //Note that these values cannot be relative paths and must be
complete paths
        string externalLocation = Environment.CurrentDirectory;
        string externalPkgPath = externalLocation +
@"\PhotoStoreDemo.package.msix";

        //Attempt registration
        bool bPackageRegistered = false;
        //bPackageRegistered =
registerPackageWithExternalLocation(externalLocation, externalPkgPath);
        if (bPackageRegistered)
```

```
        {
            //Registration succeeded, restart the app to run with identity

System.Diagnostics.Process.Start(Application.ResourceAssembly.Location,
arguments: cmdArgs?.ToString());
        }
        else //Registration failed, run without identity
        {
            Debug.WriteLine("Package Registration failed, running WITHOUT
Identity");
            SingleInstanceManager wrapper = new SingleInstanceManager();
            wrapper.Run(cmdArgs);
        }
    }
    ...
```

This example shows how to register the MSIX on first run of the app:

C#

```
[STAThread]
public static void Main(string[] cmdArgs)
{
    //If app isn't running with identity, register its package with external
identity
    if (!ExecutionMode.IsRunningWithIdentity())
    {
        //TODO - update the value of externalLocation to match the output
location of your VS Build binaries and the value of
        //externalPkgPath to match the path to your signed package with
external identity (.msix).
        //Note that these values cannot be relative paths and must be
complete paths
        string externalLocation = Environment.CurrentDirectory;
        string externalPkgPath = externalLocation +
@"\PhotoStoreDemo.package.msix";

        //Attempt registration
        if (registerPackageWithExternalLocation(externalLocation,
externalPkgPath))
        {
            //Registration succeeded, restart the app to run with identity

System.Diagnostics.Process.Start(Application.ResourceAssembly.Location,
arguments: cmdArgs?.ToString());
        }
        else //Registration failed, run without identity
        {
            Debug.WriteLine("Package Registration failed, running WITHOUT
Identity");
            SingleInstanceManager wrapper = new SingleInstanceManager();
            wrapper.Run(cmdArgs);
        }
```

```
    }
    ...
```

Finally, handle the app's activation:

C#

```
[STAThread]
public static void Main(string[] cmdArgs)
{
    //if app isn't running with identity, register its sparse package
    if (!ExecutionMode.IsRunningWithIdentity())
    {
        ...
    }
    else //App is registered and running with identity, handle launch and
activation
    {
        //Handle Sparse Package based activation e.g Share target activation
or clicking on a Tile
        // Launching the .exe directly will have activationArgs == null
        var activationArgs = AppInstance.GetActivatedEventArgs();
        if (activationArgs != null)
        {
            switch (activationArgs.Kind)
            {
                case ActivationKind.Launch:
                    HandleLaunch(activationArgs as
LaunchActivatedEventArgs);
                    break;
                case ActivationKind.ToastNotification:
                    HandleToastNotification(activationArgs as
ToastNotificationActivatedEventArgs);
                    break;
                case ActivationKind.ShareTarget: // Handle the activation as
a share target
                    HandleShareAsync(activationArgs as
ShareTargetActivatedEventArgs);
                    break;
                default:
                    HandleLaunch(null);
                    break;
            }

        }
        //This is a direct exe based launch e.g. double click app .exe or
desktop shortcut pointing to .exe
        else
        {
            SingleInstanceManager singleInstanceManager = new
SingleInstanceManager();
            singleInstanceManager.Run(cmdArgs);
```

```
        }
    }
```

Windows Share with package identity demo

The following video demonstrates how an unpackaged app can be a share target after being granted package identity and registering as a share target: https://learn-video.azurefd.net/vod/player?id=49784732-8213-43b2-b1fe-003aa218432e&locale=en-us&embedUrl=%2Fwindows%2Fapps%2Fdevelop%2Fwindows-integration%2Fintegrate-sharesheet-unpackaged

Feed providers

Article • 01/14/2025

> **Note**
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

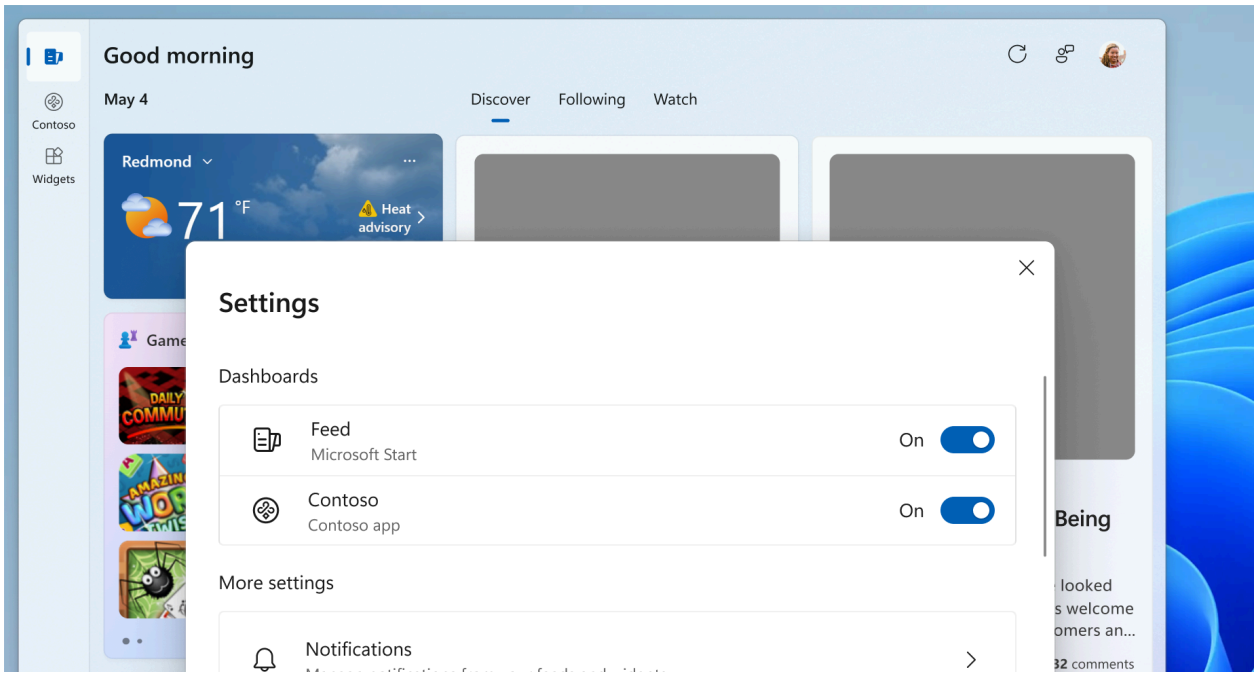
The feed providers feature in the Windows App SDK is a new integration point for third-party applications. It enables these applications to register their content feeds to be directly available within the Windows Widgets Board, enhancing the user experience by providing quick access to a variety of content directly from the desktop.

This article introduces the concept of feed providers and provides a high-level explanation the feature.

For detailed guidance on how to implement a feed provider, see these articles below:

- Implement a feed provider in a C# Windows App
- Implement a feed provider in a win32 app (C++/WinRT)
- Feed provider package manifest XML format

Feeds in the Widgets Board helps users stay on top of what matters, enabling them to easily discover useful information and empowering them to act on it. Feed providers enable users to see content from multiple apps and services at the same time. Users can access content from various apps directly on their Widgets Board without the need to open individual apps, ensuring they have the latest information at their fingertips. Users also have the control to enable or disable feeds from the Widgets Board settings, tailoring the content to their preferences.



Getting started with feed providers

The following lists the high-level steps for developing a feed provider:

1. **Register feeds** - Register your app's feeds in the app manifest. Once registered and detected, these feeds become directly available in the Widgets Board.
2. **Implement feed experience** - Develop the feed experience as a web component that will be rendered within an i-frame on the Widgets Board. Feeds will appear as pivots above the **Feeds** section of the Widgets Board.
3. **Provide personalization controls (optional)** - Each feed provider can define a personalization control dialog that allows users to customize their feed experience according to their preferences.

Limitations and considerations

- The feed providers feature is in preview.
- This feature is available only to users in the European Economic Area (EEA). In the EEA, installed apps that implement a feed provider can provide content feed in the Widgets Board.
- The feature requires using the latest Windows App SDK for app development.
- Specific technical and design guidelines must be adhered to for proper feed integration.

Next steps

For detailed guidance on how to implement a feed provider, see these articles below:

- Implement a feed provider in a C# Windows App
- Implement a feed provider in a win32 app (C++/WinRT)
- Feed provider package manifest XML format

Implement a feed provider in a C# Windows App

Article • 12/15/2023

> ⓘ Note
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

This article walks you through creating a simple feed provider that registers a feed content URI and implements the **IFeedProvider** interface. The methods of this interface are invoked by the Widgets Board to request custom query string parameters, typically to support authentication scenarios. Feed providers can support a single feed or multiple feeds.

To implement a feed provider using C++/WinRT, see Implement a feed provider in a win32 app (C++/WinRT).

Prerequisites

- Your device must have developer mode enabled. For more information see Enable your device for development.
- Visual Studio 2022 or later with the **Universal Windows Platform development** workload.

Create a new C# console app

In Visual Studio, create a new project. In the **Create a new project** dialog, set the language filter to "C#" and the platform filter to Windows, then select the Console App project template. Name the new project "ExampleFeedProvider". For this walkthrough, make sure that **Place solution and project in the same directory** is unchecked. When prompted, set the target .NET version to 6.0.

When the project loads, in **Solution Explorer** right-click the project name and select **Properties**. On the **General** page, scroll down to **Target OS** and select "Windows". Under **Target OS Version**, select version 10.022631.2787 or later.

Note that this walkthrough uses a console app that displays the console window when the feed is activated to enable easy debugging. When you are ready to publish your feed provider app, you can convert the console application to a Windows application by following the steps in Convert your console app to a Windows app.

Add references to the Windows App SDK NuGet package

This sample uses the latest stable Windows App SDK NuGet package. In **Solution Explorer**, right-click **Dependencies** and select **Manage NuGet packages...**. In the NuGet package manager, select the **Browse** tab and search for "Microsoft.WindowsAppSDK". Select the latest stable version in the **Version** drop-down and then click **Install**.

Add a FeedProvider class to handle feed operations

In Visual Studio, right-click the `ExampleFeedProvider` project in **Solution Explorer** and select **Add->Class**. In the **Add class** dialog, name the class "FeedProvider" and click **Add**. In the generated FeedProvider.cs file, update the class definition to indicate that it implements the **IFeedProvider** interface.

Create a CLSID that will be used to identify your feed provider for COM activation. Generate a GUID in Visual Studio by going to **Tools->Create GUID**. Save this GUID in a text file to be used later when packaging the feed provider app. Replace the GUID in the annotations for the **FeedProvider** class shown in the following example.

C#

```
// FeedProvider.cs
using Microsoft.Windows.Widgets.Feeds.Providers;
...
[ComVisible(true)]
[ComDefaultInterface(typeof(IFeedProvider))]
[Guid("xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx")]
public sealed class FeedProvider : IFeedProvider
```

Implement the IFeedProvider methods

In the next few sections, we'll implement the methods of the **IFeedProvider** interface.

> **Note**
>
> Objects passed into the callback methods of the **IFeedProvider** interface are only guaranteed to be valid within the callback. You should not store references to these objects because their behavior outside of the context of the callback is undefined.

OnFeedProviderEnabled

The **OnFeedProviderEnabled** method is invoked when a feed associated with the provider is created by the Widgets Board host. In the implementation of this method, generate a query string with the parameters that will be passed to the URL that provides the feed content, including any necessary authentication tokens. Create an instance of **CustomQueryParametersUpdateOptions**, passing in the **FeedProviderDefinitionId** from the event args that identifies the feed that has been enabled and the query string. Get the default **FeedManager** and call **SetCustomQueryParameters** to register the query string parameters with the Widgets Board.

C#

```
// FeedProvider.cs

public void OnFeedProviderEnabled(FeedProviderEnabledArgs args)
{
    Console.WriteLine($"{args.FeedProviderDefinitionId} feed provider was
enabled.");
    var updateOptions = new
CustomQueryParametersUpdateOptions(args.FeedProviderDefinitionId,
"param1&param2");
    FeedManager.GetDefault().SetCustomQueryParameters(updateOptions);
}
```

OnFeedProviderDisabled

OnFeedProviderDisabled is called when the Widgets Board when all of the feeds for this provider have been disabled. Feed providers are not required to perform any actions in response to these this method call. The method invocation can be used for telemetry purposes or to update the query string parameters or revoke authentication tokens, if needed. If the app only supports a single feed provider or if all feed providers supported by the app have been disabled, then the app can exit in response to this callback.

C#

```
// FeedProvider.cs
public void OnFeedProviderDisabled(FeedProviderDisabledArgs args)
{
    Console.WriteLine($"{args.FeedProviderDefinitionId} feed provider was
disabled.");
}
```

OnFeedEnabled, OnFeedDisabled

OnFeedEnabled and **OnFeedDisabled** are invoked by the Widgets Board when a feed is enabled or disabled. Feed providers are not required to perform any actions in response to these method calls. The method invocation can be used for telemetry purposes or to update the query string parameters or revoke authentication tokens, if needed.

C#

```
// FeedProvider.cs
public void OnFeedEnabled(FeedEnabledArgs args)
{
    Console.WriteLine($"{args.FeedDefinitionId} feed was enabled.");
}
```

C#

```
// FeedProvider.cs
public void OnFeedDisabled(FeedDisabledArgs args)
{
    Console.WriteLine($"{args.FeedDefinitionId} feed was disabled.");
}
```

OnCustomQueryParametersRequested

OnCustomQueryParametersRequested is raised when the Widgets Board determines that the custom query parameters associated with the feed provider need to be refreshed. For example, this method may be raised if the operation to fetch feed content from the remote web service fails. The **FeedProviderDefinitionId** property of the **CustomQueryParametersRequestedArgs** passed into this method specifies the feed for which query string params are being requested. The provider should regenerate the query string and pass it back to the Widgets Board by calling **SetCustomQueryParameters**.

C#

```
// FeedProvider.cs

public void
OnCustomQueryParametersRequested(CustomQueryParametersRequestedArgs args)
{
    Console.WriteLine($"CustomQueryParamaters were requested for
{args.FeedProviderDefinitionId}.");
    var updateOptions = new
CustomQueryParametersUpdateOptions(args.FeedProviderDefinitionId,
"param1&param2");
    FeedManager.GetDefault().SetCustomQueryParameters(updateOptions);
}
```

Implement a class factory that will instantiate FeedProvider on request

In order for the feed host to communicate with our feed provider, we must call CoRegisterClassObject. This function requires us to create an implementation of the IClassFactory that will create a class object for our **FeedProvider** class. We will implement our class factory in a self-contained helper class.

In Visual Studio, right-click the `ExampleFeedProvider` project in **Solution Explorer** and select **Add->Class**. In the **Add class** dialog, name the class "FactoryHelper" and click **Add**.

Replace the contents of the FactoryHelper.cs file with the following code. This code defines the **IClassFactory** interface and implements its two methods, CreateInstance and LockServer. This code is typical boilerplate for implementing a class factory and is not specific to the functionality of a feed provider except that we indicate that the class object being created implements the **IFeedProvider** interface.

C#

```
// FactoryHelper.cs
using Microsoft.Windows.Widgets.Feeds.Providers;
using System.Runtime.InteropServices;
using WinRT;

namespace ExampleFeedProvider
{
    namespace Com
    {
        static class Guids
        {
            public const string IClassFactory = "00000001-0000-0000-C000-
000000000046";
```

```
            public const string IUnknown = "00000000-0000-0000-C000-
000000000046";
        }

        [ComImport(), InterfaceType(ComInterfaceType.InterfaceIsIUnknown),
Guid(Guids.IClassFactory)]
        internal interface IClassFactory
        {
            [PreserveSig]
            int CreateInstance(IntPtr pUnkOuter, ref Guid riid, out IntPtr
ppvObject);
            [PreserveSig]
            int LockServer(bool fLock);
        }

        static class ClassObject
        {
            public static void Register(Guid clsid, object pUnk, out uint
cookie)
            {
                [DllImport("ole32.dll")]
                static extern int CoRegisterClassObject(
                    [MarshalAs(UnmanagedType.LPStruct)] Guid rclsid,
                    [MarshalAs(UnmanagedType.IUnknown)] object pUnk,
                    uint dwClsContext,
                    uint flags,
                    out uint lpdwRegister);

                int result = CoRegisterClassObject(clsid, pUnk, 0x4, 0x1,
out cookie);
                if (result != 0)
                {
                    Marshal.ThrowExceptionForHR(result);
                }
            }

            public static int Revoke(uint cookie)
            {
                [DllImport("ole32.dll")]
                static extern int CoRevokeClassObject(uint dwRegister);

                return CoRevokeClassObject(cookie);
            }
        }
    }

    internal class FeedProviderFactory<T> : Com.IClassFactory
            where T : IFeedProvider, new()
    {
        public int CreateInstance(IntPtr pUnkOuter, ref Guid riid, out
IntPtr ppvObject)
        {
            ppvObject = IntPtr.Zero;

            if (pUnkOuter != IntPtr.Zero)
```

```
            {
                Marshal.ThrowExceptionForHR(CLASS_E_NOAGGREGATION);
            }

            if (riid == typeof(T).GUID || riid ==
Guid.Parse(Com.Guids.IUnknown))
            {
                // Create the instance of the .NET object
                ppvObject =
MarshalInspectable<IFeedProvider>.FromManaged(new T());
            }
            else
            {
                // The object that ppvObject points to does not support the
                // interface identified by riid.
                Marshal.ThrowExceptionForHR(E_NOINTERFACE);
            }

            return 0;
        }

        int Com.IClassFactory.LockServer(bool fLock)
        {
            return 0;
        }

        private const int CLASS_E_NOAGGREGATION = -2147221232;
        private const int E_NOINTERFACE = -2147467262;
    }
}
```

Register the feed provider class object with OLE

In the Program.cs file for our executable, we will call **CoRegisterClassObject** to register our feed provider with OLE, so that the Widgets Board can interact with it. Replace the contents of Program.cs with the following code. This uses the **FeedProviderFactory** interface we defined in a previous step to register the **FeedProvider** helper class. For debugging purposes, this example calls **GetEnabledFeedProviders** on the default **FeedManager** instance to get a list of **FeedProviderInfo** objects representing the enabled feed providers. The it loops through the enabled feed providers, using the **EnabledFeedDefinitionIds** property to list all enabled feed IDs.

C#

```
// Program.cs

using Microsoft.Windows.Widgets.Feeds.Providers;
using Microsoft.Windows.Widgets.Providers;
```

```
using System;
using System.Runtime.InteropServices;

namespace ExampleFeedProvider
{

    public static class Program
    {
        [DllImport("kernel32.dll")]
        static extern IntPtr GetConsoleWindow();

        [MTAThread]
        static void Main(string[] args)
        {
            Console.WriteLine("FeedProvider Starting...");
            if (args.Length > 0 && args[0] == "-RegisterProcessAsComServer")
            {
                WinRT.ComWrappersSupport.InitializeComWrappers();

                uint registrationHandle;
                var factory = new FeedProviderFactory<FeedProvider>();
                Com.ClassObject.Register(typeof(FeedProvider).GUID, factory,
out registrationHandle);

                Console.WriteLine("Feed Provider registered.");

                var existingFeedProviders =
FeedManager.GetDefault().GetEnabledFeedProviders();
                if (existingFeedProviders != null)
                {
                    Console.WriteLine($"There are
{existingFeedProviders.Length} FeedProviders currently outstanding:");
                    foreach (var feedProvider in existingFeedProviders)
                    {
                        Console.WriteLine($"  ProviderId:
{feedProvider.FeedProviderDefinitionId}, DefinitionIds: ");
                        var m = WidgetManager.GetDefault().GetWidgetIds();
                        if (feedProvider.EnabledFeedDefinitionIds != null)
                        {
                            foreach (var enabledFeedId in
feedProvider.EnabledFeedDefinitionIds)
                            {
                                Console.WriteLine($" {enabledFeedId} ");
                            }
                        }
                    }
                }
                if (GetConsoleWindow() != IntPtr.Zero)
                {
                    Console.WriteLine("Press ENTER to exit.");
                    Console.ReadLine();
                }
                else
                {
                    while (true)
```

```
                    {
                        // You should fire an event when all the outstanding
                        // FeedProviders have been disabled and exit the
app.
                    }
                }
            }
            else
            {
                Console.WriteLine("Not being launched to service Feed
Provider... exiting.");
            }
        }
    }
}
```

Note that this code example imports the GetConsoleWindow function to determine if the app is running as a console application, the default behavior for this walkthrough. If function returns a valid pointer, we write debug information to the console. Otherwise, the app is running as a Windows app. In that case, we wait for the event that we set in **OnFeedProviderDisabled** method when the list of enabled feed providers is empty, and the we exit the app. For information on converting the example console app to a Windows app, see Convert your console app to a Windows app.

Package your feed provider app

In the current release, only packaged apps can be registered as feed providers. The following steps will take you through the process of packaging your app and updating the app manifest to register your app with the OS as a feed provider.

Create an MSIX packaging project

In **Solution Explorer**, right-click your solution and select **Add->New Project...**. In the **Add a new project** dialog, select the "Windows Application Packaging Project" template and click **Next**. Set the project name to "ExampleFeedProviderPackage" and click **Create**. When prompted, set the target version to build 22621 or later and click **OK**. Next, right-click the ExampleFeedProviderPackage project and select **Add->Project reference**. Select the **ExampleFeedProvider** project and click OK.

Add Windows App SDK package reference to the packaging project

You need to add a reference to the Windows App SDK nuget package to the MSIX packaging project. In **Solution Explorer**, double-click the ExampleFeedProviderPackage project to open the ExampleFeedProviderPackage.wapproj file. Add the following xml inside the **Project** element.

XML

```
<!--ExampleWidgetProviderPackage.wapproj-->
<ItemGroup>
    <PackageReference Include="Microsoft.WindowsAppSDK"
Version="1.5.231116003-experimentalpr">
        <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

> **Note**
>
> Make sure the **Version** specified in the **PackageReference** element matches the latest stable version you referenced in the previous step.

If the correct version of the Windows App SDK is already installed on the computer and you don't want to bundle the SDK runtime in your package, you can specify the package dependency in the Package.appxmanifest file for the ExampleFeedProviderPackage project.

XML

```
<!--Package.appxmanifest-->
...
<Dependencies>
...
    <PackageDependency Name="Microsoft.WindowsAppRuntime.1.5.233430000-
experimental1" MinVersion="2000.638.7.0" Publisher="CN=Microsoft
Corporation, O=Microsoft Corporation, L=Redmond, S=Washington, C=US" />
...
</Dependencies>
...
```

Update the package manifest

In **Solution Explorer** right-click the `Package.appxmanifest` file and select **View Code** to open the manifest xml file. Next you need to add some namespace declarations for the app package extensions we will be using. Add the following namespace definitions to the top-level Package element.

XML

```
<!-- Package.appmanifest -->
<Package
  ...
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"
```

Inside the **Application** element, create a new empty element named **Extensions**. Make sure this comes after the closing tag for **uap:VisualElements**.

XML

```
<!-- Package.appxmanifest -->
<Application>
...
    <Extensions>

    </Extensions>
</Application>
```

The first extension we need to add is the ComServer extension. This registers the entry point of the executable with the OS. This extension is the packaged app equivalent of registering a COM server by setting a registry key, and is not specific to widget providers.Add the following **com:Extension** element as a child of the **Extensions** element. Change the GUID in the **Id** attribute of the **com:Class** element to the GUID that you generated in a previous step when defining the **FeedProvider** class.

XML

```
<!-- Package.appxmanifest -->
<Extensions>
    <com:Extension Category="windows.comServer">
        <com:ComServer>
            <com:ExeServer
Executable="ExampleFeedProvider\ExampleFeedProvider.exe" Arguments="-
RegisterProcessAsComServer" DisplayName="C# Feed Provider App">
                <com:Class Id="xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"
DisplayName="FeedProvider" />
            </com:ExeServer>
        </com:ComServer>
    </com:Extension>
</Extensions>
```

Next, add the extension that registers the app as a feed provider. Paste the uap3:Extension element in the following code snippet, as a child of the **Extensions**

element. Be sure to replace the **ClassId** attribute of the **COM** element with the GUID you used in previous steps.

XML

```
<!-- Package.appxmanifest -->
<Extensions>
    ...
    <uap3:Extension Category="windows.appExtension">
        <uap3:AppExtension Name="com.microsoft.windows.widgets.feeds"
DisplayName="ContosoFeed" Id="com.examplewidgets.examplefeed"
PublicFolder="Public">
            <uap3:Properties>
                <FeedProvider Icon="ms-appx:Assets\StoreLogo.png"
Description="FeedDescription">
                    <Activation>
                        <!-- Apps exports COM interface which implements
IFeedProvider -->
                        <CreateInstance ClassId="xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx" />
                    </Activation>
                    <Definitions>
                        <Definition Id="Contoso_Feed"
                            DisplayName="Contoso_Feed Feed"
                            Description="Feed representing Contoso"
                            ContentUri="https://www.contoso.com/"
                            Icon="ms-appx:Images\StoreLogo.png">
                        </Definition>
                        <Definition Id="Fabrikam_Feed"
                            DisplayName="Fabrikam Feed"
                            Description="Feed representing Example"
                            ContentUri="https://www.fabrikam.com/"
                            Icon="ms-appx:Images\StoreLogo.png">
                        </Definition>
                    </Definitions>
                </FeedProvider>
            </uap3:Properties>
        </uap3:AppExtension>
    </uap3:Extension>
</Extensions>
```

For detailed descriptions and format information for all of these elements, see Feed provider package manifest XML format.

Testing your feed provider

Make sure you have selected the architecture that matches your development machine from the **Solution Platforms** drop-down, for example "x64". In **Solution Explorer**, right-click your solution and select **Build Solution**. Once this is done, right-click your

ExampleWidgetProviderPackage and select **Deploy**. The console app should launch on deploy and you will see the feeds get enabled in the console output. Open the Widgets Board and you should see the new feeds in the tabs along the top of the feeds section.

Debugging your feed provider

After you have pinned your feeds, the Widget Platform will start your feed provider application in order to receive and send relevant information about the feed. To debug the running feed you can either attach a debugger to the running feed provider application or you can set up Visual Studio to automatically start debugging the feed provider process once it's started.

In order to attach to the running process:

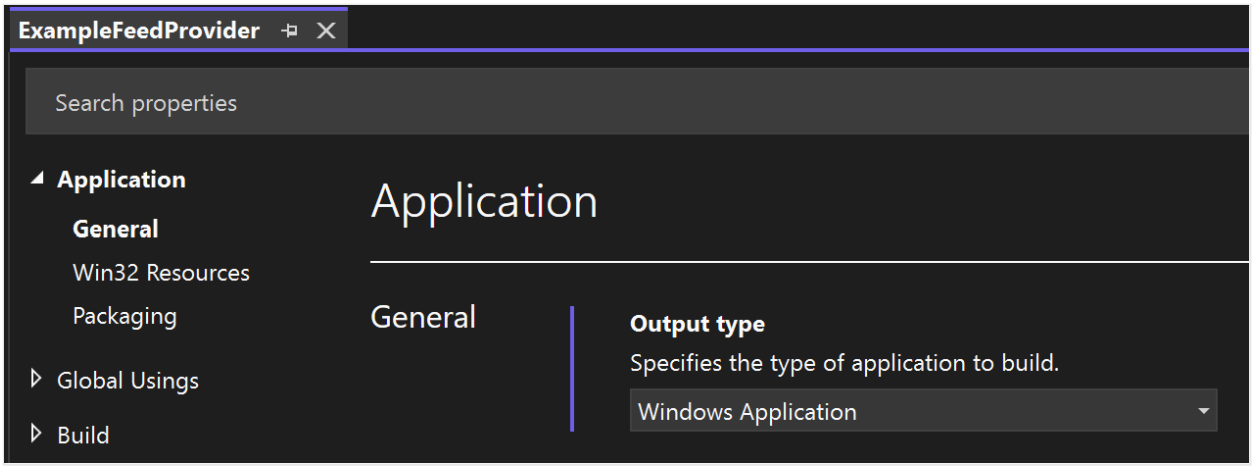
1. In Visual Studio click **Debug -> Attach to process**.
2. Filter the processes and find your desired feed provider application.
3. Attach the debugger.

In order to automatically attach the debugger to the process when it's initially started:

1. In Visual Studio click **Debug -> Other Debug Targets -> Debug Installed App Package**.
2. Filter the packages and find your desired feed provider package.
3. Select it and check the box that says Do not launch, but debug my code when it starts.
4. Click **Attach**.

Convert your console app to a Windows app

To convert the console app created in this walkthrough to a Windows app, right-click the **ExampleFeedProvider** project in **Solution Explorer** and select **Properties**. Under Application->General change the **Output type** from "Console Application" to "Windows Application".



Publishing your feed provider app

After you have developed and tested your feed provider you can publish your app on the Microsoft Store in order for users to install your feeds on their devices. For step by step guidance for publishing an app, see Publish your app in the Microsoft Store.

The Feeds Store Collection

After your app has been published on the Microsoft Store, you can request for your app to be included in the feeds Store Collection that helps users discover apps that feature Windows feeds. To submit your request, see Submit your Feed/Board for addition to the Store Collection.

Implement a feed provider in a win32 app (C++/WinRT)

Article • 12/15/2023

> **Note**
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

This article walks you through creating a simple feed provider that registers a feed content URI and implements the **IFeedProvider** interface. The methods of this interface are invoked by the Widgets Board to request custom query string parameters, typically to support authentication scenarios. Feed providers can support a single feed or multiple feeds.

To implement a feed provider using C++/WinRT, see Implement a feed provider in a C# Windows app (C++/WinRT).

Prerequisites

- Your device must have developer mode enabled. For more information see Enable your device for development.
- Visual Studio 2022 or later with the **Universal Windows Platform development** workload. Make sure to add the component for C++ (v143) from the optional dropdown.

Create a new C++/WinRT win32 console app

In Visual Studio, create a new project. In the **Create a new project** dialog, set the language filter to "C++" and the platform filter to Windows, then select the Windows Console Application (C++/WinRT) project template. Name the new project "ExampleFeedProvider". For this walkthrough, make sure that **Place solution and project in the same directory** is unchecked. When prompted, set the target Windows version for the app to 10.022631.2787 or later.

Add references to the Windows App SDK and Windows Implementation Library NuGet packages

This sample uses the latest stable Windows App SDK NuGet package. In **Solution Explorer**, right-click **References** and select **Manage NuGet packages...**. In the NuGet package manager, select the **Browse** tab and search for "Microsoft.WindowsAppSDK". Select the latest stable version in the **Version** drop-down and then click **Install**.

This sample also uses the Windows Implementation Library NuGet package. In **Solution Explorer**, right-click **References** and select **Manage NuGet packages...**. In the NuGet package manager, select the **Browse** tab and search for "Microsoft.Windows.ImplementationLibrary". Select the latest version in the **Version** drop-down and then click **Install**.

In the precompiled header file, pch.h, add the following include directives.

C++

```
//pch.h
#pragma once
#include <wil/cppwinrt.h>
#include <wil/resource.h>
...
#include <winrt/Microsoft.Windows.Widgets.Providers.h>
```

> ⓘ **Note**
>
> You must include the wil/cppwinrt.h header first, before any WinRT headers.

In order to handle shutting down the feed provider app correctly, we need to a custom implementation of **winrt::get_module_lock**. We pre-declare the **SignalLocalServerShutdown** method which will be defined in our main.cpp file and will set an event that signals the app to exit. Add the following code to your pch.h file, just below the `#pragma once` directive, before the other includes.

C++

```
//pch.h
#include <stdint.h>
#include <combaseapi.h>

// In .exe local servers the class object must not contribute to the module
```

```
ref count, and use
// winrt::no_module_lock, the other objects must and this is the hook into
the C++ WinRT ref counting system
// that enables this.
void SignalLocalServerShutdown();

namespace winrt
{
    inline auto get_module_lock() noexcept
    {
        struct service_lock
        {
            uint32_t operator++() noexcept
            {
                return ::CoAddRefServerProcess();
            }

            uint32_t operator--() noexcept
            {
                const auto ref = ::CoReleaseServerProcess();

                if (ref == 0)
                {
                    SignalLocalServerShutdown();
                }
                return ref;
            }
        };

        return service_lock{};
    }
}

#define WINRT_CUSTOM_MODULE_LOCK
```

Add a FeedProvider class to handle feed operations

In Visual Studio, right-click the `ExampleFeedProvider` project in **Solution Explorer** and select **Add->Class**. In the **Add class** dialog, name the class "FeedProvider" and click **Add**.

Declare a class that implements the IFeedProvider interface

The **IFeedProvider** interface defines methods that the Widgets Board will invoke to initiate operations with the feed provider. Replace the empty class definition in the

FeedProvider.h file with the following code. This code declares a structure that implements the **IFeedProvider** interface and declares prototypes for the interface methods.

```
C++
```

```
// FeedProvider.h
#pragma once
struct FeedProvider : winrt::implements<FeedProvider,
winrt::Microsoft::Windows::Widgets::Feeds::Providers::IFeedProvider>
{
    FeedProvider() {}

    /* IFeedrovider required functions that need to be implemented */
    void
OnFeedProviderEnabled(winrt::Microsoft::Windows::Widgets::Feeds::Providers::
FeedProviderEnabledArgs args);
    void
OnFeedProviderDisabled(winrt::Microsoft::Windows::Widgets::Feeds::Providers:
:FeedProviderDisabledArgs args);
    void
OnFeedEnabled(winrt::Microsoft::Windows::Widgets::Feeds::Providers::FeedEnab
ledArgs args);
    void
OnFeedDisabled(winrt::Microsoft::Windows::Widgets::Feeds::Providers::FeedDis
abledArgs args);
    void
OnCustomQueryParametersRequested(winrt::Microsoft::Windows::Widgets::Feeds::
Providers::CustomQueryParametersRequestedArgs args);
    /* IFeedProvider required functions that need to be implemented */

};
```

Implement the IFeedProvider methods

In the next few sections, we'll implement the methods of the **IFeedProvider** interface. Before diving into the interface methods, add the following lines to `FeedProvider.cpp`, after the include directives, to pull the feed provider APIs into the **winrt** namespace and allow access to the map we declared in the previous step.

> **Note**
>
> Objects passed into the callback methods of the **IFeedProvider** interface are only guaranteed to be valid within the callback. You should not store references to these objects because their behavior outside of the context of the callback is undefined.

C++

```
// WidgetProvider.cpp
namespace winrt
{
    using namespace Microsoft::Windows::Widgets::Feeds::Providers;
}
```

OnFeedProviderEnabled

The **OnFeedProviderEnabled** method is invoked when a feed associated with the provider is created by the Widgets Board host. In the implementation of this method, generate a query string with the parameters that will be passed to the URL that provides the feed content, including any necessary authentication tokens. Create an instance of **CustomQueryParametersUpdateOptions**, passing in the **FeedProviderDefinitionId** from the event args that identifies the feed that has been enabled and the query string. Get the default **FeedManager** and call **SetCustomQueryParameters** to register the query string parameters with the Widgets Board.

C#

```
// FeedProvider.cs
void
FeedProvider::OnFeedProviderEnabled(winrt::Microsoft::Windows::Widgets::Feed
s::Providers::FeedProviderEnabledArgs args)
{
    std::wstringstream wstringstream;
wstringstream << args.FeedProviderDefinitionId().c_str() << L" feed provider
was enabled." << std::endl;
    _putws(wstringstream.str().c_str());

    auto updateOptions =
winrt::CustomQueryParametersUpdateOptions(args.FeedProviderDefinitionId(),
L"param1&param2");

winrt::FeedManager::GetDefault().SetCustomQueryParameters(updateOptions);
}
```

OnFeedProviderDisabled

OnFeedProviderDisabled is called when the Widgets Board when all of the feeds for this provider have been disabled. Feed providers are not required to perform any actions in response to these this method call. The method invocation can be used for telemetry

purposes or to update the query string parameters or revoke authentication tokens, if needed. If the app only supports a single feed provider or if all feed providers supported by the app have been disabled, then the app can exit in response to this callback.

C#

```
// FeedProvider.cs

void
FeedProvider::OnFeedProviderDisabled(winrt::Microsoft::Windows::Widgets::Fee
ds::Providers::FeedProviderDisabledArgs args)
{
    std::wstringstream wstringstream;
    wstringstream << args.FeedProviderDefinitionId().c_str() << L" feed
provider was disabled." << std::endl;
    _putws(wstringstream.str().c_str());
}
```

OnFeedEnabled, OnFeedDisabled

OnFeedEnabled and **OnFeedDisabled** are invoked by the Widgets Board when a feed is enabled or disabled. Feed providers are not required to perform any actions in response to these method calls. The method invocation can be used for telemetry purposes or to update the query string parameters or revoke authentication tokens, if needed.

C#

```
// FeedProvider.cs

void
FeedProvider::OnFeedEnabled(winrt::Microsoft::Windows::Widgets::Feeds::Provi
ders::FeedEnabledArgs args)
{
    std::wstringstream wstringstream;
    wstringstream << args.FeedDefinitionId().c_str() << L" feed was
enabled." << std::endl;
    _putws(wstringstream.str().c_str());
}
```

C#

```
// FeedProvider.cs

void
FeedProvider::OnFeedDisabled(winrt::Microsoft::Windows::Widgets::Feeds::Prov
iders::FeedDisabledArgs args)
{
    std::wstringstream wstringstream;
```

```
    wstringstream << args.FeedDefinitionId().c_str() << L" feed was
disabled." << std::endl;
    _putws(wstringstream.str().c_str());
}
```

OnCustomQueryParametersRequested

OnCustomQueryParametersRequested is raised when the Widgets Board determines that the custom query parameters associated with the feed provider need to be refreshed. For example, this method may be raised if the operation to fetch feed content from the remote web service fails. The **FeedProviderDefinitionId** property of the **CustomQueryParametersRequestedArgs** passed into this method specifies the feed for which query string params are being requested. The provider should regenerate the query string and pass it back to the Widgets Board by calling **SetCustomQueryParameters**.

C#

```
// FeedProvider.cs

void
FeedProvider::OnCustomQueryParametersRequested(winrt::Microsoft::Windows::Wi
dgets::Feeds::Providers::CustomQueryParametersRequestedArgs args)
{
    std::wstringstream wstringstream;
    wstringstream << L"CustomQueryParameters were requested for " <<
args.FeedProviderDefinitionId().c_str() << std::endl;
    _putws(wstringstream.str().c_str());

    auto updateOptions =
winrt::CustomQueryParametersUpdateOptions(args.FeedProviderDefinitionId(),
L"param1&param2");

winrt::FeedManager::GetDefault().SetCustomQueryParameters(updateOptions);
}
```

Register a class factory that will instantiate FeedProvider on request

Add the header that defines the **FeedProvider** class to the includes at the top of your app's `main.cpp` file. We will also be including **mutex** here.

C++

```
// main.cpp
...
#include "FeedProvider.h"
#include <mutex>
```

Declare the event that will trigger our app to exit and the **SignalLocalServerShutdown** function that will set the event. Paste the following code in main.cpp.

C++

```
// main.cpp
wil::unique_event g_shudownEvent(wil::EventOptions::None);

void SignalLocalServerShutdown()
{
    g_shudownEvent.SetEvent();
}
```

Next, you will need to create a CLSID that will be used to identify your feed provider for COM activation. Generate a GUID in Visual Studio by going to **Tools->Create GUID**. Select the option "static const GUID =" and click **Copy** and then paste that into `main.cpp`. Update the GUID definition with the following C++/WinRT syntax, setting the GUID variable name feed_provider_clsid. Leave the commented version of the GUID because you will need this format later, when packaging your app.

C++

```
// main.cpp
...
// {80F4CB41-5758-4493-9180-4FB8D480E3F5}
static constexpr GUID feed_provider_clsid
{
    0x80f4cb41, 0x5758, 0x4493, { 0x91, 0x80, 0x4f, 0xb8, 0xd4, 0x80, 0xe3,
0xf5 }
};
```

Add the following class factory definition to `main.cpp`. This is mostly boilerplate code that is not specific to feed provider implementations. Note that **CoWaitForMultipleObjects** waits for our shutdown event to be triggered before the app exits.

C++

```
// main.cpp
template <typename T>
struct SingletonClassFactory : winrt::implements<SingletonClassFactory<T>,
```

```
IClassFactory>
{
    STDMETHODIMP CreateInstance(
        ::IUnknown* outer,
        GUID const& iid,
        void** result) noexcept final
    {
        *result = nullptr;

        std::unique_lock lock(mutex);

        if (outer)
        {
            return CLASS_E_NOAGGREGATION;
        }

        if (!instance)
        {
            instance = winrt::make<FeedProvider>();
        }

        return instance.as(iid, result);
    }

    STDMETHODIMP LockServer(BOOL) noexcept final
    {
        return S_OK;
    }

private:
    T instance{ nullptr };
    std::mutex mutex;
};

int main()
{
    winrt::init_apartment();
    wil::unique_com_class_object_cookie feedProviderFactory;
    auto factory =
winrt::make<SingletonClassFactory<winrt::Microsoft::Windows::Widgets::Feeds:
:Providers::IFeedProvider>>();

    winrt::check_hresult(CoRegisterClassObject(
        feed_provider_clsid,
        factory.get(),
        CLSCTX_LOCAL_SERVER,
        REGCLS_MULTIPLEUSE,
        feedProviderFactory.put()));

    DWORD index{};
    HANDLE events[] = { g_shudownEvent.get() };
    winrt::check_hresult(CoWaitForMultipleObjects(CWMO_DISPATCH_CALLS |
CWMO_DISPATCH_WINDOW_MESSAGES,
        INFINITE,
        static_cast<ULONG>(std::size(events)), events, &index));
```

```
    return 0;
}
```

Package your feed provider app

In the current release, only packaged apps can be registered as feed providers. The following steps will take you through the process of packaging your app and updating the app manifest to register your app with the OS as a feed provider.

Create an MSIX packaging project

In **Solution Explorer**, right-click your solution and select **Add->New Project...**. In the **Add a new project** dialog, select the "Windows Application Packaging Project" template and click **Next**. Set the project name to "ExampleFeedProviderPackage" and click **Create**. When prompted, set the target version to version 1809 or later and click **OK**. Next, right-click the ExampleFeedProviderPackage project and select **Add->Project reference**. Select the **ExampleFeedProvider** project and click OK.

Add Windows App SDK package reference to the packaging project

You need to add a reference to the Windows App SDK nuget package to the MSIX packaging project. In **Solution Explorer**, double-click the ExampleFeedProviderPackage project to open the ExampleFeedProviderPackage.wapproj file. Add the following xml inside the **Project** element.

XML

```
<!--ExampleFeedProviderPackage.wapproj-->
<ItemGroup>
    <PackageReference Include="Microsoft.WindowsAppSDK"
Version="1.5.231116003-experimentalpr">
        <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

> ⓘ **Note**
>
> Make sure the **Version** specified in the **PackageReference** element matches the latest stable version you referenced in the previous step.

If the correct version of the Windows App SDK is already installed on the computer and you don't want to bundle the SDK runtime in your package, you can specify the package dependency in the Package.appxmanifest file for the ExampleFeedProviderPackage project.

XML

```
<!--Package.appxmanifest-->
...
<Dependencies>
...
    <PackageDependency Name="Microsoft.WindowsAppRuntime.1.5.233430000-
experimental1" MinVersion="2000.638.7.0" Publisher="CN=Microsoft
Corporation, O=Microsoft Corporation, L=Redmond, S=Washington, C=US" />
...
</Dependencies>
...
```

Update the package manifest

In **Solution Explorer** right-click the `Package.appxmanifest` file and select **View Code** to open the manifest xml file. Next you need to add some namespace declarations for the app package extensions we will be using. Add the following namespace definitions to the top-level Package element.

XML

```
<!-- Package.appmanifest -->
<Package
  ...
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"
```

Inside the **Application** element, create a new empty element named **Extensions**. Make sure this comes after the closing tag for **uap:VisualElements**.

XML

```
<!-- Package.appxmanifest -->
<Application>
...
    <Extensions>

    </Extensions>
</Application>
```

The first extension we need to add is the ComServer extension. This registers the entry point of the executable with the OS. This extension is the packaged app equivalent of registering a COM server by setting a registry key, and is not specific to feed providers.Add the following **com:Extension** element as a child of the **Extensions** element. Change the GUID in the **Id** attribute of the **com:Class** element to the GUID you generated in a previous step.

XML

```
<!-- Package.appxmanifest -->
<Extensions>
    <com:Extension Category="windows.comServer">
        <com:ComServer>
            <com:ExeServer
Executable="ExampleFeedProvider\ExampleFeedProvider.exe" Arguments="-
RegisterProcessAsComServer" DisplayName="C++ Feed Provider App">
                <com:Class Id="xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"
DisplayName="FeedProvider" />
            </com:ExeServer>
        </com:ComServer>
    </com:Extension>
</Extensions>
```

Next, add the extension that registers the app as a feed provider. Paste the uap3:Extension element in the following code snippet, as a child of the **Extensions** element. Be sure to replace the **ClassId** attribute of the **COM** element with the GUID you used in previous steps.

XML

```
<!-- Package.appxmanifest -->
<Extensions>
    ...
    <uap3:Extension Category="windows.appExtension">
        <uap3:AppExtension Name="com.microsoft.windows.widgets.feeds"
DisplayName="ContosoFeed" Id="com.examplewidgets.examplefeed"
PublicFolder="Public">
            <uap3:Properties>
                <FeedProvider Icon="ms-appx:Assets\StoreLogo.png"
Description="FeedDescription">
                    <Activation>
                        <!-- Apps exports COM interface which implements
IFeedProvider -->
                        <CreateInstance ClassId="xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx" />
                    </Activation>
                    <Definitions>
                        <Definition Id="Contoso_Feed"
                            DisplayName="Contoso_Feed Feed"
                            Description="Feed representing Contoso"
```

```
                            ContentUri="https://www.contoso.com/"
                            Icon="ms-appx:Images\StoreLogo.png">
                        </Definition>
                        <Definition Id="Fabrikam_Feed"
                            DisplayName="Fabrikam Feed"
                            Description="Feed representing Example"
                            ContentUri="https://www.fabrikam.com/"
                            Icon="ms-appx:Images\StoreLogo.png">
                        </Definition>
                    </Definitions>
                </FeedProvider>
            </uap3:Properties>
        </uap3:AppExtension>
    </uap3:Extension>
</Extensions>
```

For detailed descriptions and format information for all of these elements, see Feed provider package manifest XML format.

Add icons to your packaging project

In **Solution Explorer**, right-click your **ExampleFeedProviderPackage** and select **Add->New Folder**. Name this folder ProviderAssets as this is what was used in the `Package.appxmanifest` from the previous step. This is where we will store our **Icon** for our feeds. Once you add your desired Icons , make sure the image names match what comes after **Path=ProviderAssets** in your `Package.appxmanifest` or the feeds will not show up in the Widget Board.

Testing your feed provider

Make sure you have selected the architecture that matches your development machine from the **Solution Platforms** drop-down, for example "x64". In **Solution Explorer**, right-click your solution and select **Build Solution**. Once this is done, right-click your **ExampleWidgetProviderPackage** and select **Deploy**. The console app should launch on deploy and you will see the feeds get enabled in the console output. Open the Widgets Board and you should see the new feeds in the tabs along the top of the feeds section.

Debugging your feed provider

After you have pinned your feeds, the Widget Platform will start your feed provider application in order to receive and send relevant information about the feed. To debug the running feed you can either attach a debugger to the running feed provider

application or you can set up Visual Studio to automatically start debugging the feed provider process once it's started.

In order to attach to the running process:

1. In Visual Studio click **Debug -> Attach to process**.
2. Filter the processes and find your desired feed provider application.
3. Attach the debugger.

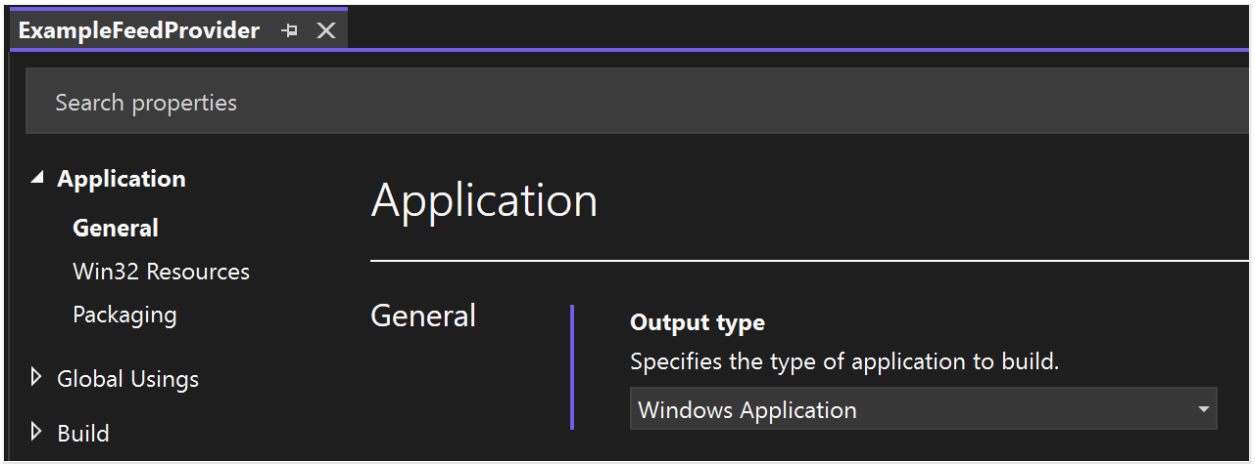
In order to automatically attach the debugger to the process when it's initially started:

1. In Visual Studio click **Debug -> Other Debug Targets -> Debug Installed App Package**.
2. Filter the packages and find your desired feed provider package.
3. Select it and check the box that says Do not launch, but debug my code when it starts.
4. Click **Attach**.

Convert your console app to a Windows app

To convert the console app created in this walkthrough to a Windows app:

1. Right-click on the ExampleWidgetProvider project in **Solution Explorer** and select **Properties**. Navigate to **Linker -> System** and change **SubSystem** from "Console" to "Windows". This can also be done by adding <SubSystem>Windows</SubSystem> to the <Link>..</Link> section of the .vcxproj.
2. In main.cpp, change `int main()` to `int WINAPI wWinMain(_In_ HINSTANCE /*hInstance*/, _In_opt_ HINSTANCE /*hPrevInstance*/, _In_ PWSTR pCmdLine, _In_ int /*nCmdShow*/)`.



Publishing your feed provider app

After you have developed and tested your feed provider you can publish your app on the Microsoft Store in order for users to install your feeds on their devices. For step by step guidance for publishing an app, see Publish your app in the Microsoft Store.

The Feeds Store Collection

After your app has been published on the Microsoft Store, you can request for your app to be included in the feeds Store Collection that helps users discover apps that feature Windows feeds. To submit your request, see Submit your Feed/Board for addition to the Store Collection.

Feed provider package manifest XML format

Article • 09/24/2024

> **Note**
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

In order to be displayed on the Widgets Board, apps that support Windows feeds must register their feed provider with the system. For Win32 apps, only packaged apps are currently supported and feed providers specify their registration information in the app package manifest file. This article documents the XML format for feed registration. See the Example section for a code listing of an example package manifest for a Win32 feed provider.

App extension

The app package manifest file supports many different extensions and features for Windows apps. The app package manifest format is defined by a set of schemas that are documented in the Package manifest schema reference. Feed providers declare their registration information within the uap3:AppExtension. The **Name** attribute of the extension must be set to "com.microsoft.windows.widgets.feeds".

Feed providers should include the uap3:Properties as the child of **uap3:AppExtension**. The package manifest schema does not enforce the structure of the **uap3:Properties** element other than requiring well-formed XML. The rest of this article describes the XML format that the Widgets Board expects in order to successfully register a feed provider.

XML

```
<uap3:Extension Category="windows.appExtension">
  <uap3:AppExtension Name="com.microsoft.windows.widgets.feeds"
DisplayName="ContosoApp" Id="ContosoApp" PublicFolder="Public">
    <uap3:Properties>
      <!-- Feed provider registration content goes here -->
    </uap3:Properties>
  </uap3:AppExtension>
</uap3:Extension>
```

Element hierarchy

FeedProvider

Activation

CreateInstance

Definitions

Definition

FeedProvider

The root element of the feed provider registration information.

Expand table

Attribute	Type	Required	Description	Default value
Description	string	Yes	A short description of the feed provider.	N/A
DisplayName	string	Yes	The name of the feed provider that is displayed on the Widgets Board.	N/A
Icon	string	Yes	The package-relative path to an icon image file that is displayed in the Widgets Board.	N/A
Id	string	Yes	An ID that identifies the feed provider. Feed provider implementations use this string to determine or specify which of the app's feed providers is being referenced for each operation. This string must be unique for all feed providers defined within the app manifest file.	N/A

Activation

Specifies activation information for the feed provider.

CreateInstance

CreateInstance should be specified for Win32-based feed providers that implement the **IFeedProvider** interface. The system will activate the interface with a call to

CoCreateInstance. The **ClassId** attribute specifies the CLSID for the CreateInstance server that implements the **IFeedProvider** interface.

Expand table

Attribute	Type	Required	Description	Default value
ClassId	GUID	Yes	The CLSID for the CreateInstance server that implements the feed provider.	N/A

Definitions

The container element for one or more feed registrations.

Definition

Represents the registration for a single feed.

Expand table

Attribute	Type	Required	Description	Default value
Id	string	Yes	An ID that identifies the feed. Feed provider implementations use this string to determine or specify which of the app's feeds is being referenced for each operation. This string must be unique for all feeds defined within the app manifest file.	N/A
DisplayName	string	Yes	The name of the feed that is displayed on the Widgets Board.	N/A
Description	string	Yes	A short description of the feed.	N/A
ContentUri	string	Yes	The URI from which feed content is retrieved.	N/A
Icon	string	Yes	The package-relative path to an icon image file that is displayed in the Widgets Board.	N/A
WebRequestFilter	string	No	A web request filter string specifying the set of URLs for which the resource requests will be redirected to the feed provider's implementation of **IFeedResourceProvider**. The pattern is expressed using the format	N/A

Attribute	Type	Required	Description	Default value
			described in Match Patterns. The filter string in the registration must use Punycode where necessary. All content types will be redirected when matched so the filter should only resolve to content intended to be obtained through the **IFeedResourceProvider** in the application.	
ExcludedRegions	string	No	A list of regions where the feed should not be available. Feeds can specify **ExcludedRegions** or **ExclusiveRegions** but must not specify both in a single feed definition. The value of the attribute is a comma separated list of two character region codes.	N/A
ExclusiveRegions	string	No	A list of the only regions where the feed should be available. Feeds can specify **ExcludedRegions** or **ExclusiveRegions** but must not specify both in single feed definition. The value of the attribute is a comma separated list of two character region codes.	N/A

You can use localized resources instead of string literals for the UI-facing attribute values. For more information, see Localize strings in your UI and app package manifest.

Example

The following code example illustrates the usage of the feed package manifest XML format.

XML

```
<uap3:AppExtension Name="com.microsoft.windows.widgets.feeds"
DisplayName="ContosoApp" Id="ContosoApp" PublicFolder="Public">
  <uap3:Properties>
      <FeedProvider Description="ms-resource:ProviderDescription" Icon="ms-
appx:Images\ContosoProviderIcon.png">
          <Activation>
              <CreateInstance ClassId="ECB883FD-3755-4E1C-BECA-D3397A3FF15C"
/>
          </Activation>
          <Definitions>
              <Definition Id="Contoso_Feed"
                  DisplayName="ms-resource:FeedDisplayName"
                  Description="ms-resource:FeedDescription"
```

```
                    ContentUri="https://contoso.com/news"
                    Icon="ms-appx:Images\ContosoFeedIcon.png"

WebRequestFilter="https://contoso.com/*/feed/appResource/*"
                    ExcludedRegions="FR,DE,IT">
                </Definition>
            </Definitions>
        </FeedProvider>
    </uap3:Properties>
</uap3:AppExtension>
```

Widget providers

Article • 03/09/2023

Windows widgets are small UI containers that display text and graphics supplied by a Windows app or Progressive Web App (PWA). The Adaptive Cards format used by Windows widgets enables dynamic binding of the data that populates the widget UI. To update your widget, your app or service will implement a widget service provider that responds to requests from the Widgets host and returns JSON strings specifying both the visual template and the associated data for your widget.

For an overview of the Windows widgets experience and design guidance for creating your own widgets, see Windows widgets.

Currently you can implement a widget provider using a packaged Win32 desktop app or a Progressive Web App (PWA). For more information see:

- Implement a widget provider in a win32 app (C#)
- Implement a widget provider in a win32 app (C++/WinRT)
- Build PWA-driven widgets

For API reference documentation for implementing widget providers, see the Microsoft.Windows.Widgets.Providers namespace.

For a walkthrough of the basics of creating a widget and implementing a widget provider, watch the *Tabs vs Spaces* episode "Create Widgets for Windows 11".
https://learn-video.azurefd.net/vod/player?show=tabs-vs-spaces&ep=create-widgets-for-windows-11&locale=en-us&embedUrl=%2Fwindows%2Fapps%2Fdevelop%2Fwidgets%2Fwidget-providers

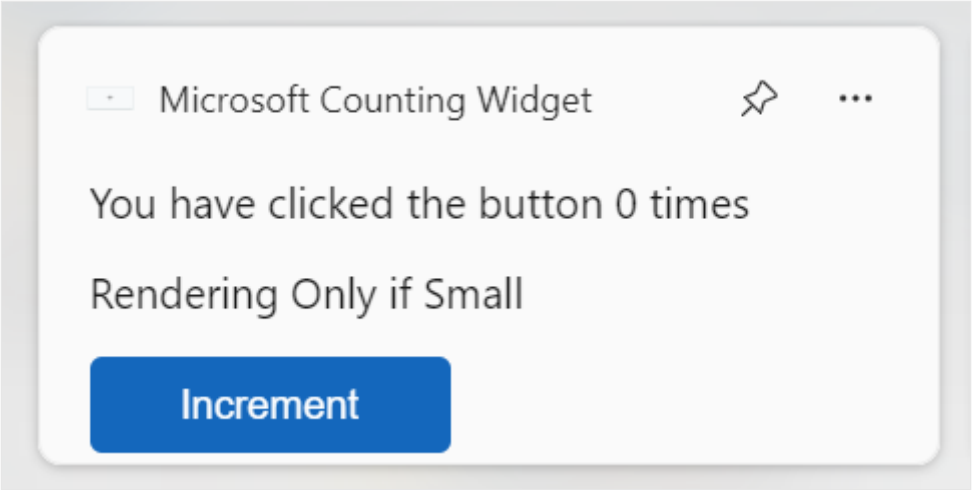
Implement a widget provider in a C# Windows App

Article • 10/02/2023

This article walks you through creating a simple widget provider that implements the IWidgetProvider interface. The methods of this interface are invoked by the widget host to request the data that defines a widget or to let the widget provider respond to a user action on a widget. Widget providers can support a single widget or multiple widgets. In this example, we will define two different widgets. One widget is a mock weather widget that illustrates some of the formatting options provided by the Adaptive Cards framework. The second widget will demonstrate user actions and the custom widget state feature by maintaining a counter that is incremented whenever the user clicks on a button displayed on the widget.



This sample code in this article is adapted from the Windows App SDK Widgets Sample. To implement a widget provider using C++/WinRT, see Implement a widget provider in a win32 app (C++/WinRT).

Prerequisites

- Your device must have developer mode enabled. For more information see Enable your device for development.
- Visual Studio 2022 or later with the **Universal Windows Platform development** workload. Make sure to add the component for C++ (v143) from the optional dropdown.

Create a new C# console app

In Visual Studio, create a new project. In the **Create a new project** dialog, set the language filter to "C#" and the platform filter to Windows, then select the Console App project template. Name the new project "ExampleWidgetProvider". When prompted, set the target .NET version to 8.0.

When the project loads, in **Solution Explorer** right-click the project name and select **Properties**. On the **General** page, scroll down to **Target OS** and select "Windows". Under **Target OS Version**, select version 10.0.19041.0 or later.

To update your project to support .NET 8.0, in **Solution Explorer** right-click the project name and select **Edit Project File**. Inside of **PropertyGroup**, add the following **RuntimeIdentifiers** element.

XML

```
<RuntimeIdentifiers>win-x86;win-x64;win-arm64</RuntimeIdentifiers>
```

Note that this walkthrough uses a console app that displays the console window when the widget is activated to enable easy debugging. When you are ready to publish your widget provider app, you can convert the console application to a Windows application by following the steps in Convert your console app to a Windows app.

Add references to the Windows App SDK

This sample uses the latest stable Windows App SDK NuGet package. In **Solution Explorer**, right-click **Dependencies** and select **Manage NuGet packages...**. In the NuGet package manager, select the **Browse** tab and search for "Microsoft.WindowsAppSDK". Select the latest stable version in the **Version** drop-down and then click **Install**.

Add a WidgetProvider class to handle widget operations

In Visual Studio, right-click the `ExampleWidgetProvider` project in **Solution Explorer** and select **Add->Class**. In the **Add class** dialog, name the class "WidgetProvider" and click **Add**. In the generated WidgetProvider.cs file, update the class definition to indicate that it implements the **IWidgetProvider** interface.

C#

```
// WidgetProvider.cs
internal class WidgetProvider : IWidgetProvider
```

Prepare to track enabled widgets

A widget provider can support a single widget or multiple widgets. Whenever the widget host initiates an operation with the widget provider, it passes an ID to identify the widget associated with the operation. Each widget also has an associated name and a state value that can be used to store custom data. For this example, we'll declare a simple helper structure to store the ID, name, and data for each pinned widget. Widgets also can be in an active state, which is discussed in the Activate and Deactivate section below, and we will track this state for each widget with a boolean value. Add the following definition to the WidgetProvider.cs file, inside the **ExampleWidgetProvider** namespace, but outside of the **WidgetProvider** class definition.

C#

```
// WidgetProvider.cs

public class CompactWidgetInfo
{
    public string? widgetId { get; set; }
    public string? widgetName { get; set; }
    public int customState = 0;
    public bool isActive = false;

}
```

Inside the **WidgetProvider** class definition in WidgetProvider.cs, add a member for the map that will maintain the list of enabled widgets, using the widget ID as the key for each entry.

C#

```
// WidgetProvider.cs

// Class member of WidgetProvider
public static Dictionary<string, CompactWidgetInfo> RunningWidgets = new
Dictionary<string, CompactWidgetInfo>();
```

Declare widget template JSON strings

This example will declare some static strings to define the JSON templates for each widget. For convenience, these templates are stored in the member variables of the **WidgetProvider** class. If you need a general storage for the templates - they can be included as part of the application package: Accessing Package Files. For information on creating the widget template JSON document, see Create a widget template with the Adaptive Card Designer.

In the latest release, apps that implement Windows widgets can customize the header that is displayed for their widget in the Widgets Board, overriding the default presentation. For more information, see Customize the widget header area.

> ⓘ **Note**
>
> In the latest release, apps that implement Windows widgets can choose to populate the widget content with HTML served from a specified URL instead of supplying content in the Adaptive Card schema format in the JSON payload passed from the provider to the Widgets Board. Widget providers must still provide an

Adaptive Card JSON payload, so the implementation steps in this walkthrough are applicable to web widgets. For more information, see Web widget providers.

C#

```
// WidgetProvider.cs

// Class members of WidgetProvider
        const string weatherWidgetTemplate = """
{
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "type": "AdaptiveCard",
    "version": "1.0",
    "speak": "<s>The forecast for Seattle January 20 is mostly clear with a
High of 51 degrees and Low of 40 degrees</s>",
    "backgroundImage":

Implement the IWidgetProvider methods

In the next few sections, we'll implement the methods of the **IWidgetProvider** interface. The helper method **UpdateWidget** that is called in several of these method implementations will be shown later in this article.

> ⓘ Note
>
> Objects passed into the callback methods of the **IWidgetProvider** interface are only guaranteed to be valid within the callback. You should not store references to these objects because their behavior outside of the context of the callback is undefined.

CreateWidget

The widget host calls CreateWidget when the user has pinned one of your app's widgets in the widget host. First, this method gets the ID and name of the associated widget and adds a new instance of our helper structure, **CompactWidgetInfo**, to the collection of

enabled widgets. Next, we send the initial template and data for the widget, which is encapsulated in the **UpdateWidget** helper method.

C#

```
// WidgetProvider.cs

public void CreateWidget(WidgetContext widgetContext)
{
    var widgetId = widgetContext.Id; // To save RPC calls
    var widgetName = widgetContext.DefinitionId;
    CompactWidgetInfo runningWidgetInfo = new CompactWidgetInfo() { widgetId
= widgetId, widgetName = widgetName };
    RunningWidgets[widgetId] = runningWidgetInfo;

    // Update the widget
    UpdateWidget(runningWidgetInfo);
}
```

DeleteWidget

The widget host calls DeleteWidget when the user has unpinned one of your app's widgets from the widget host. When this occurs, we will remove the associated widget from our list of enabled widgets so that we don't send any further updates for that widget.

C#

```
// WidgetProvider.cs

public void DeleteWidget(string widgetId, string customState)
{
    RunningWidgets.Remove(widgetId);

    if(RunningWidgets.Count == 0)
    {
        emptyWidgetListEvent.Set();
    }
}
```

For this example, in addition to removing the widget with the specified from the list of enabled widgets, we also check to see if the list is now empty, and if so, we set an event that will be used later to allow the app to exit when there are no enabled widgets. Inside your class definition, add the declaration of the ManualResetEvent and a public accessor function.

C#

```
// WidgetProvider.cs
static ManualResetEvent emptyWidgetListEvent = new ManualResetEvent(false);

public static ManualResetEvent GetEmptyWidgetListEvent()
{
    return emptyWidgetListEvent;
}
```

OnActionInvoked

The widget host calls OnActionInvoked when the user interacts with an action you defined in your widget template. For the counter widget used in this example, an action was declared with a **verb** value of "inc" in the JSON template for the widget. The widget provider code will use this **verb** value to determine what action to take in response to the user interaction.

JSON

```
...
    "actions": [
        {
            "type": "Action.Execute",
            "title": "Increment",
            "verb": "inc"
        }
    ],
...
```

In the **OnActionInvoked** method, get the verb value by checking the **Verb** property of the WidgetActionInvokedArgs passed into the method. If the verb is "inc", then we know we are going to increment the count in the custom state for the widget. From the **WidgetActionInvokedArgs**, get the WidgetContext object and then the **WidgetId** to get the ID for the widget that is being updated. Find the entry in our enabled widgets map with the specified ID and then update the custom state value that is used to store the number of increments. Finally, update the widget content with the new value with the **UpdateWidget** helper function.

C#

```
// WidgetProvider.cs

public void OnActionInvoked(WidgetActionInvokedArgs actionInvokedArgs)
{
    var verb = actionInvokedArgs.Verb;
```

```
        if (verb == "inc")
        {
            var widgetId = actionInvokedArgs.WidgetContext.Id;
            // If you need to use some data that was passed in after
            // Action was invoked, you can get it from the args:
            var data = actionInvokedArgs.Data;
            if (RunningWidgets.ContainsKey(widgetId))
            {
                var localWidgetInfo = RunningWidgets[widgetId];
                // Increment the count
                localWidgetInfo.customState++;
                UpdateWidget(localWidgetInfo);
            }
        }
}
```

For information about the **Action.Execute** syntax for Adaptive Cards, see Action.Execute. For guidance about designing interaction for widgets, see Widget interaction design guidance

OnWidgetContextChanged

In the current release, OnWidgetContextChanged is only called when the user changes the size of a pinned widget. You can choose to return a different JSON template/data to the widget host depending on what size is requested. You can also design the template JSON to support all the available sizes using conditional rendering based on the value of **host.widgetSize**. If you don't need to send a new template or data to account for the size change, you can use the **OnWidgetContextChanged** for telemetry purposes.

C#

```
// WidgetProvider.cs

public void OnWidgetContextChanged(WidgetContextChangedArgs
contextChangedArgs)
{
    var widgetContext = contextChangedArgs.WidgetContext;
    var widgetId = widgetContext.Id;
    var widgetSize = widgetContext.Size;
    if (RunningWidgets.ContainsKey(widgetId))
    {
        var localWidgetInfo = RunningWidgets[widgetId];
        UpdateWidget(localWidgetInfo);
    }
}
```

Activate and Deactivate

The Activate method is called to notify the widget provider that the widget host is currently interested in receiving updated content from the provider. For example, it could mean that the user is currently actively viewing the widget host. The Deactivate method is called to notify the widget provider that the widget host is no longer requesting content updates. These two methods define a window in which the widget host is most interested in showing the most up-to-date content. Widget providers can send updates to the widget at any time, such as in response to a push notification, but as with any background task, it's important to balance providing up-to-date content with resource concerns like battery life.

Activate and **Deactivate** are called on a per-widget basis. This example tracks the active status of each widget in the **CompactWidgetInfo** helper struct. In the **Activate** method, we call the **UpdateWidget** helper method to update our widget. Note that the time window between **Activate** and **Deactivate** may be small, so it's recommended that you try to make your widget update code path as quick as possible.

C#

```
// WidgetProvider.cs

public void Activate(WidgetContext widgetContext)
{
    var widgetId = widgetContext.Id;

    if (RunningWidgets.ContainsKey(widgetId))
    {
        var localWidgetInfo = RunningWidgets[widgetId];
        localWidgetInfo.isActive = true;

        UpdateWidget(localWidgetInfo);
    }
}
public void Deactivate(string widgetId)
{
    if (RunningWidgets.ContainsKey(widgetId))
    {
        var localWidgetInfo = RunningWidgets[widgetId];
        localWidgetInfo.isActive = false;
    }
}
```

Update a widget

Define the **UpdateWidget** helper method to update an enabled widget. In this example, we check the name of the widget in the **CompactWidgetInfo** helper struct passed into the method, and then set the appropriate template and data JSON based on which widget is being updated. A **WidgetUpdateRequestOptions** is initialized with the template, data, and custom state for the widget being updated. Call WidgetManager::GetDefault to get an instance of the WidgetManager class and then call UpdateWidget to send the updated widget data to the widget host.

C#

```
// WidgetProvider.cs

void UpdateWidget(CompactWidgetInfo localWidgetInfo)
{
    WidgetUpdateRequestOptions updateOptions = new
WidgetUpdateRequestOptions(localWidgetInfo.widgetId);

    string? templateJson = null;
    if (localWidgetInfo.widgetName == "Weather_Widget")
    {
        templateJson = weatherWidgetTemplate.ToString();
    }
    else if (localWidgetInfo.widgetName == "Counting_Widget")
    {
        templateJson = countWidgetTemplate.ToString();
    }

    string? dataJson = null;
    if (localWidgetInfo.widgetName == "Weather_Widget")
    {
        dataJson = "{}";
    }
    else if (localWidgetInfo.widgetName == "Counting_Widget")
    {
        dataJson = "{ \"count\": " + localWidgetInfo.customState.ToString()
+ " }";
    }

    updateOptions.Template = templateJson;
    updateOptions.Data = dataJson;
    // You can store some custom state in the widget service that you will
be able to query at any time.
    updateOptions.CustomState= localWidgetInfo.customState.ToString();
    WidgetManager.GetDefault().UpdateWidget(updateOptions);
}
```

Initialize the list of enabled widgets on startup

When our widget provider is first initialized, it's a good idea to ask **WidgetManager** if there are any running widgets that our provider is currently serving. It will help to recover the app to the previous state in case of the computer restart or the provider crash. Call **WidgetManager.GetDefault** to get the default widget manager instance for the app. Then call GetWidgetInfos, which returns an array of WidgetInfo objects. Copy the widget IDs, names, and custom state into the helper struct **CompactWidgetInfo** and save it to the **RunningWidgets** member variable. Paste the following code into the class definition for the **WidgetProvider** class.

C#

```
// WidgetProvider.cs

public WidgetProvider()
{
    var runningWidgets = WidgetManager.GetDefault().GetWidgetInfos();

    foreach (var widgetInfo in runningWidgets)
    {
        var widgetContext = widgetInfo.WidgetContext;
        var widgetId = widgetContext.Id;
        var widgetName = widgetContext.DefinitionId;
        var customState = widgetInfo.CustomState;
        if (!RunningWidgets.ContainsKey(widgetId))
        {
            CompactWidgetInfo runningWidgetInfo = new CompactWidgetInfo() {
widgetId = widgetId, widgetName = widgetName };
            try
            {
                // If we had any save state (in this case we might have some
state saved for Counting widget)
                // convert string to required type if needed.
                int count = Convert.ToInt32(customState.ToString());
                runningWidgetInfo.customState = count;
            }
            catch
            {

            }
            RunningWidgets[widgetId] = runningWidgetInfo;
        }
    }
}
```

Implement a class factory that will instantiate WidgetProvider on request

In order for the widget host to communicate with our widget provider, we must call CoRegisterClassObject. This function requires us to create an implementation of the IClassFactory that will create a class object for our **WidgetProvider** class. We will implement our class factory in a self-contained helper class.

In Visual Studio, right-click the `ExampleWidgetProvider` project in **Solution Explorer** and select **Add->Class**. In the **Add class** dialog, name the class "FactoryHelper" and click **Add**.

Replace the contents of the FactoryHelper.cs file with the following code. This code defines the **IClassFactory** interface and implements it's two methods, CreateInstance and LockServer. This code is typical boilerplate for implementing a class factory and is not specific to the functionality of a widget provider except that we indicate that the class object being created implements the **IWidgetProvider** interface.

C#

```
// FactoryHelper.cs

using Microsoft.Windows.Widgets.Providers;
using System.Runtime.InteropServices;
using WinRT;

namespace COM
{
    static class Guids
    {
        public const string IClassFactory = "00000001-0000-0000-C000-
000000000046";
        public const string IUnknown = "00000000-0000-0000-C000-
000000000046";
    }

    ///
    /// IClassFactory declaration
    ///
    [ComImport, ComVisible(false),
InterfaceType(ComInterfaceType.InterfaceIsIUnknown),
Guid(COM.Guids.IClassFactory)]
    internal interface IClassFactory
    {
        [PreserveSig]
        int CreateInstance(IntPtr pUnkOuter, ref Guid riid, out IntPtr
ppvObject);
        [PreserveSig]
        int LockServer(bool fLock);
    }

    [ComVisible(true)]
    class WidgetProviderFactory<T> : IClassFactory
```

```
    where T : IWidgetProvider, new()
    {
        public int CreateInstance(IntPtr pUnkOuter, ref Guid riid, out
IntPtr ppvObject)
        {
            ppvObject = IntPtr.Zero;

            if (pUnkOuter != IntPtr.Zero)
            {
                Marshal.ThrowExceptionForHR(CLASS_E_NOAGGREGATION);
            }

            if (riid == typeof(T).GUID || riid ==
Guid.Parse(COM.Guids.IUnknown))
            {
                // Create the instance of the .NET object
                ppvObject =
MarshalInspectable<IWidgetProvider>.FromManaged(new T());
            }
            else
            {
                // The object that ppvObject points to does not support the
                // interface identified by riid.
                Marshal.ThrowExceptionForHR(E_NOINTERFACE);
            }

            return 0;
        }

        int IClassFactory.LockServer(bool fLock)
        {
            return 0;
        }

        private const int CLASS_E_NOAGGREGATION = -2147221232;
        private const int E_NOINTERFACE = -2147467262;

    }
}
```

Create a GUID representing the CLSID for your widget provider

Next, you need to create a GUID representing the CLSID that will be used to identify your widget provider for COM activation. The same value will also be used when packaging your app. Generate a GUID in Visual Studio by going to **Tools->Create GUID**. Select the registry format option and click **Copy** and then paste that into a text file so that you can copy it later.

Register the widget provider class object with OLE

In the Program.cs file for our executable, we will call **CoRegisterClassObject** to register our widget provider with OLE, so that the widget host can interact with it. Replace the contents of Program.cs with the following code. This code imports the **CoRegisterClassObject** function and calls it, passing in the **WidgetProviderFactory** interface we defined in a previous step. Be sure to update the **CLSID_Factory** variable declaration to use the GUID you generated in the previous step.

C#

```
// Program.cs

using System.Runtime.InteropServices;
using ComTypes = System.Runtime.InteropServices.ComTypes;
using Microsoft.Windows.Widgets;
using ExampleWidgetProvider;
using COM;
using System;

[DllImport("kernel32.dll")]
static extern IntPtr GetConsoleWindow();

[DllImport("ole32.dll")]

static extern int CoRegisterClassObject(
            [MarshalAs(UnmanagedType.LPStruct)] Guid rclsid,
            [MarshalAs(UnmanagedType.IUnknown)] object pUnk,
            uint dwClsContext,
            uint flags,
            out uint lpdwRegister);

[DllImport("ole32.dll")] static extern int CoRevokeClassObject(uint
dwRegister);

Console.WriteLine("Registering Widget Provider");
uint cookie;

Guid CLSID_Factory = Guid.Parse("XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX");
CoRegisterClassObject(CLSID_Factory, new
WidgetProviderFactory<WidgetProvider>(), 0x4, 0x1, out cookie);
Console.WriteLine("Registered successfully. Press ENTER to exit.");
Console.ReadLine();

if (GetConsoleWindow() != IntPtr.Zero)
{
    Console.WriteLine("Registered successfully. Press ENTER to exit.");
    Console.ReadLine();
}
else
```

```
{
    // Wait until the manager has disposed of the last widget provider.
    using (var emptyWidgetListEvent =
WidgetProvider.GetEmptyWidgetListEvent())
    {
        emptyWidgetListEvent.WaitOne();
    }

    CoRevokeClassObject(cookie);
}
```

Note that this code example imports the GetConsoleWindow function to determine if the app is running as a console application, the default behavior for this walkthrough. If function returns a valid pointer, we write debug information to the console. Otherwise, the app is running as a Windows app. In that case, we wait for the event that we set in DeleteWidget method when the list of enabled widgets is empty, and the we exit the app. For information on converting the example console app to a Windows app, see Convert your console app to a Windows app.

Package your widget provider app

In the current release, only packaged apps can be registered as widget providers. The following steps will take you through the process of packaging your app and updating the app manifest to register your app with the OS as a widget provider.

Create an MSIX packaging project

In **Solution Explorer**, right-click your solution and select **Add->New Project...**. In the **Add a new project** dialog, select the "Windows Application Packaging Project" template and click **Next**. Set the project name to "ExampleWidgetProviderPackage" and click **Create**. When prompted, set the target version to version 1809 or later and click **OK**. Next, right-click the ExampleWidgetProviderPackage project and select **Add->Project reference**. Select the **ExampleWidgetProvider** project and click OK.

Add Windows App SDK package reference to the packaging project

You need to add a reference to the Windows App SDK nuget package to the MSIX packaging project. In **Solution Explorer**, double-click the ExampleWidgetProviderPackage project to open the ExampleWidgetProviderPackage.wapproj file. Add the following xml inside the **Project** element.

XML

```
<!--ExampleWidgetProviderPackage.wapproj-->
<ItemGroup>
    <PackageReference Include="Microsoft.WindowsAppSDK"
Version="1.2.221116.1">
        <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

> **Note**
>
> Make sure the **Version** specified in the **PackageReference** element matches the latest stable version you referenced in the previous step.

If the correct version of the Windows App SDK is already installed on the computer and you don't want to bundle the SDK runtime in your package, you can specify the package dependency in the Package.appxmanifest file for the ExampleWidgetProviderPackage project.

XML

```
<!--Package.appxmanifest-->
...
<Dependencies>
...
    <PackageDependency Name="Microsoft.WindowsAppRuntime.1.2-preview2"
MinVersion="2000.638.7.0" Publisher="CN=Microsoft Corporation, O=Microsoft
Corporation, L=Redmond, S=Washington, C=US" />
...
</Dependencies>
...
```

Update the package manifest

In **Solution Explorer** right-click the `Package.appxmanifest` file and select **View Code** to open the manifest xml file. Next you need to add some namespace declarations for the app package extensions we will be using. Add the following namespace definitions to the top-level Package element.

XML

```
<!-- Package.appmanifest -->
<Package
  ...
```

```
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"
```

Inside the **Application** element, create a new empty element named **Extensions**. Make sure this comes after the closing tag for **uap:VisualElements**.

XML

```
<!-- Package.appxmanifest -->
<Application>
...
    <Extensions>

    </Extensions>
</Application>
```

The first extension we need to add is the ComServer extension. This registers the entry point of the executable with the OS. This extension is the packaged app equivalent of registering a COM server by setting a registry key, and is not specific to widget providers.Add the following **com:Extension** element as a child of the **Extensions** element. Change the GUID in the **Id** attribute of the **com:Class** element to the GUID you generated in a previous step.

XML

```
<!-- Package.appxmanifest -->
<Extensions>
    <com:Extension Category="windows.comServer">
        <com:ComServer>
            <com:ExeServer
Executable="ExampleWidgetProvider\ExampleWidgetProvider.exe"
DisplayName="ExampleWidgetProvider">
                <com:Class Id="xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"
DisplayName="ExampleWidgetProvider" />
            </com:ExeServer>
        </com:ComServer>
    </com:Extension>
</Extensions>
```

Next, add the extension that registers the app as a widget provider. Paste the uap3:Extension element in the following code snippet, as a child of the **Extensions** element. Be sure to replace the **ClassId** attribute of the **COM** element with the GUID you used in previous steps.

XML

```
<!-- Package.appxmanifest -->
<Extensions>
    ...
    <uap3:Extension Category="windows.appExtension">
        <uap3:AppExtension Name="com.microsoft.windows.widgets"
DisplayName="WidgetTestApp" Id="ContosoWidgetApp" PublicFolder="Public">
            <uap3:Properties>
                <WidgetProvider>
                    <ProviderIcons>
                        <Icon Path="Images\StoreLogo.png" />
                    </ProviderIcons>
                    <Activation>
                        <!-- Apps exports COM interface which implements
IWidgetProvider -->
                        <CreateInstance ClassId="xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx" />
                    </Activation>

                    <TrustedPackageFamilyNames>

<TrustedPackageFamilyName>Microsoft.MicrosoftEdge.Stable_8wekyb3d8bbwe</Trus
tedPackageFamilyName>
                    </TrustedPackageFamilyNames>

                    <Definitions>
                        <Definition Id="Weather_Widget"
                            DisplayName="Weather Widget"
                            Description="Weather Widget Description"
                            AllowMultiple="true">
                            <Capabilities>
                                <Capability>
                                    <Size Name="small" />
                                </Capability>
                                <Capability>
                                    <Size Name="medium" />
                                </Capability>
                                <Capability>
                                    <Size Name="large" />
                                </Capability>
                            </Capabilities>
                            <ThemeResources>
                                <Icons>
                                    <Icon
Path="ProviderAssets\Weather_Icon.png" />
                                </Icons>
                                <Screenshots>
                                    <Screenshot
Path="ProviderAssets\Weather_Screenshot.png" DisplayAltText="For
accessibility" />
                                </Screenshots>
                                <!-- DarkMode and LightMode are optional -->
                                <DarkMode />
                                <LightMode />
                            </ThemeResources>
```

```
                        </Definition>
                        <Definition Id="Counting_Widget"
                                DisplayName="Microsoft Counting Widget"
                                Description="Couting Widget Description">
                            <Capabilities>
                                <Capability>
                                    <Size Name="small" />
                                </Capability>
                            </Capabilities>
                            <ThemeResources>
                                <Icons>
                                    <Icon
Path="ProviderAssets\Counting_Icon.png" />
                                </Icons>
                                <Screenshots>
                                    <Screenshot
Path="ProviderAssets\Counting_Screenshot.png" DisplayAltText="For
accessibility" />
                                </Screenshots>
                                <!-- DarkMode and LightMode are optional -->
                                <DarkMode>

                                </DarkMode>
                                <LightMode />
                            </ThemeResources>
                        </Definition>
                    </Definitions>
                </WidgetProvider>
            </uap3:Properties>
        </uap3:AppExtension>
    </uap3:Extension>
</Extensions>
```

For detailed descriptions and format information for all of these elements, see Widget provider package manifest XML format.

Add icons and other images to your packaging project

In **Solution Explorer**, right-click your **ExampleWidgetProviderPackage** and select **Add->New Folder**. Name this folder ProviderAssets as this is what was used in the `Package.appxmanifest` from the previous step. This is where we will store our **Icons** and **Screenshots** for our widgets. Once you add your desired Icons and Screenshots, make sure the image names match what comes after **Path=ProviderAssets** in your `Package.appxmanifest` or the widgets will not show up in the widget host.

For information about the design requirements for screenshot images and the naming conventions for localized screenshots, see Integrate with the widget picker.

Testing your widget provider

Make sure you have selected the architecture that matches your development machine from the **Solution Platforms** drop-down, for example "x64". In **Solution Explorer**, right-click your solution and select **Build Solution**. Once this is done, right-click your **ExampleWidgetProviderPackage** and select **Deploy**. In the current release, the only supported widget host is the Widgets Board. To see the widgets you will need to open the Widgets Board and select **Add widgets** in the top right. Scroll to the bottom of the available widgets and you should see the mock **Weather Widget** and **Microsoft Counting Widget** that were created in this tutorial. Click on the widgets to pin them to your widgets board and test their functionality.

Debugging your widget provider

After you have pinned your widgets, the Widget Platform will start your widget provider application in order to receive and send relevant information about the widget. To debug the running widget you can either attach a debugger to the running widget provider application or you can set up Visual Studio to automatically start debugging the widget provider process once it's started.

In order to attach to the running process:

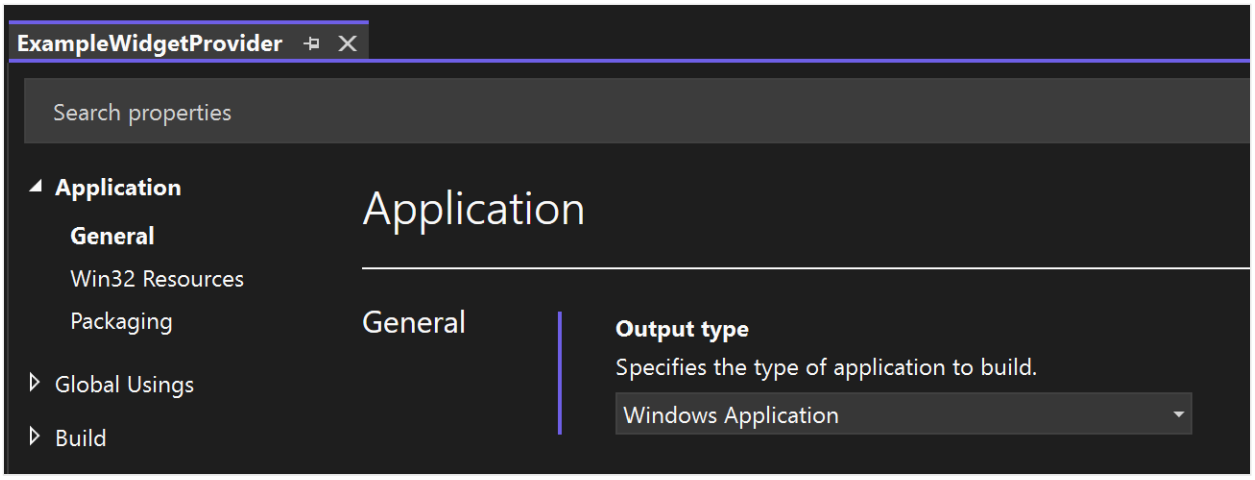
1. In Visual Studio click **Debug -> Attach to process**.
2. Filter the processes and find your desired widget provider application.
3. Attach the debugger.

In order to automatically attach the debugger to the process when it's initially started:

1. In Visual Studio click **Debug -> Other Debug Targets -> Debug Installed App Package**.
2. Filter the packages and find your desired widget provider package.
3. Select it and check the box that says Do not launch, but debug my code when it starts.
4. Click **Attach**.

Convert your console app to a Windows app

To convert the console app created in this walkthrough to a Windows app, right-click the **ExampleWidgetProvider** project in **Solution Explorer** and select **Properties**. Under Application->General change the **Output type** from "Console Application" to "Windows Application".

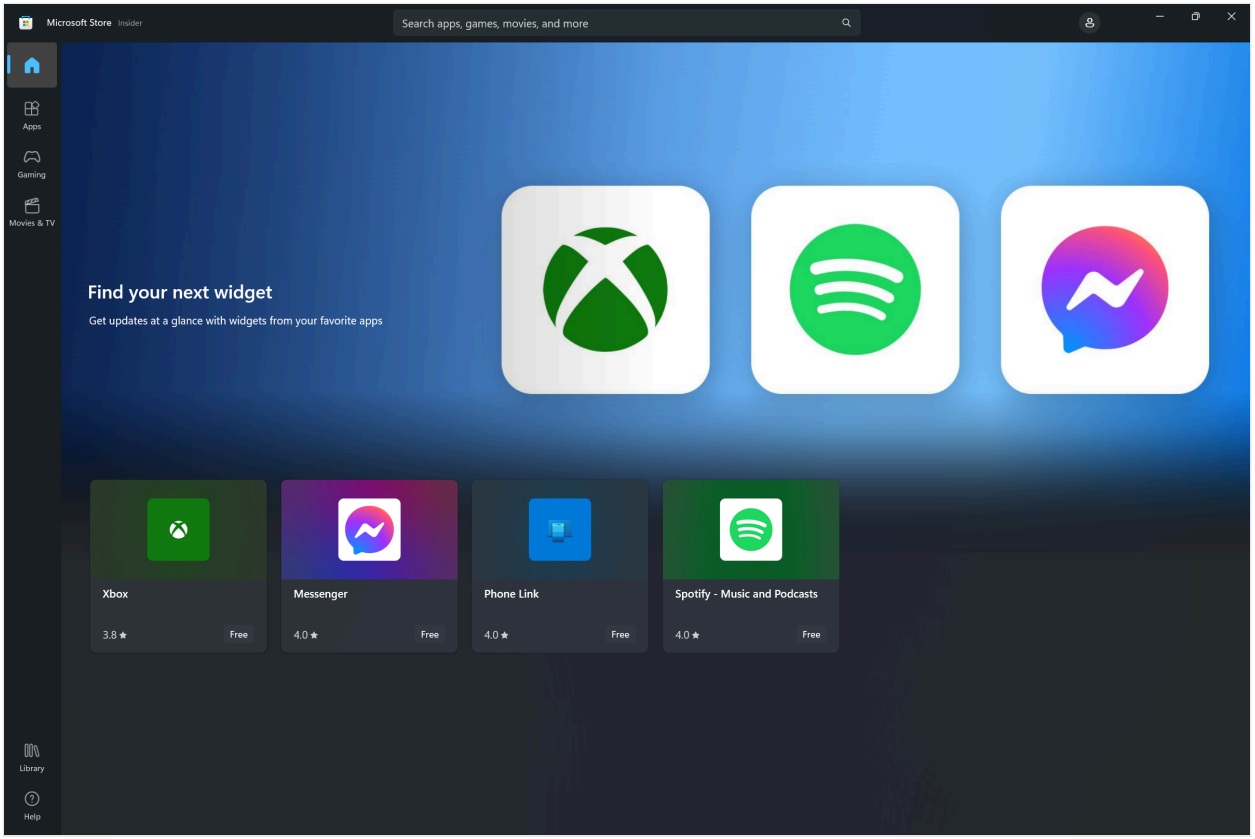


Publishing your widget

After you have developed and tested your widget you can publish your app on the Microsoft Store in order for users to install your widgets on their devices. For step by step guidance for publishing an app, see Publish your app in the Microsoft Store.

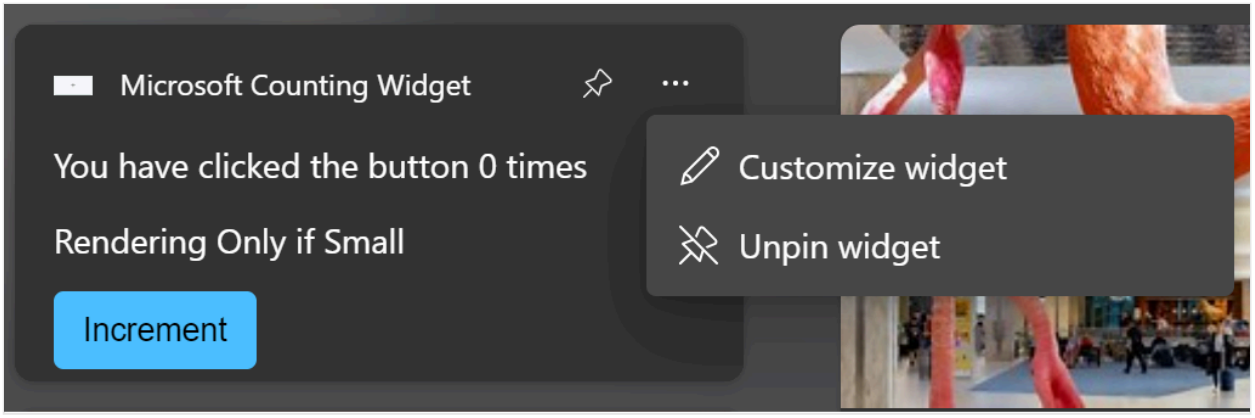
The widgets Store Collection

After your app has been published on the Microsoft Store, you can request for your app to be included in the widgets Store Collection that helps users discover apps that feature Windows Widgets. To submit your request, see Submit your Widget information for addition to the Store Collection .



Implementing widget customization

Starting with Windows App SDK 1.4, widgets can support user customization. When this feature is implemented, a **Customize widget** option is added to the ellipsis menu above the **Unpin widget** option.



The following steps summarize the process for widget customization.

1. In normal operation, the widget provider responds to requests from the widget host with the template and data payloads for the regular widget experience.
2. The user clicks the **Customize widget** button in the ellipsis menu.
3. The widget raises the **OnCustomizationRequested** event on the widget provider to indicate that the user has requested the widget customization experience.
4. The widget provider sets an internal flag to indicate that the widget is in customization mode. While in customization mode, the widget provider sends the JSON templates for the widget customization UI instead of the regular widget UI.
5. While in customization mode, the widget provider receives **OnActionInvoked** events as the user interacts with the customization UI and adjusts its internal configuration and behavior based on the user's actions.
6. When the action associated with the **OnActionInvoked** event is the app-defined "exit customization" action, the widget provider resets its internal flag to indicate that it is no longer in customization mode and resumes sending the visual and data JSON templates for the regular widget experience, reflecting the changes requested during customization. It's possible for the user to close out of the customization experience without clicking the app-defined exit customization action. In this case, the IWidgetProviderAnalytics.OnAnalyticsInfoReported will be raised, and the WidgetAnalyticsInfoReportedArgs.AnalyticsJson will have an *interactionKind* of "exitCustomization".
7. The widget provider persists the customization options to disk or the cloud so that the changes are preserved between invocations of the widget provider.

> ⓘ **Note**

There is a known bug with the Windows Widget Board, for widgets built using the Windows App SDK, that causes the ellipsis menu to become unresponsive after the customization card is shown.

In typical Widget customization scenarios, the user will choose what data is displayed on the widget or adjust visual presentation of the widget. For simplicity, the example in this section will add customization behavior that allows the user to reset the counter of the counting widget implemented in the previous steps.

> ⓘ **Note**
>
> Widget customization is only supported in Windows App SDK 1.4 and later. Make sure you update the references in your project to the latest version of the Nuget package.

Update the package manifest to declare customization support

To let the widget host know that the widget supports customization, add the attribute **IsCustomizable** to the **Definition** element for the widget and set it to true.

XML

```
...
<Definition Id="Counting_Widget"
    DisplayName="Microsoft Counting Widget"
    Description="CONFIG counting widget description"
    IsCustomizable="true">
...
```

Track when a widget is in customization mode

The example in this article uses the helper struct **CompactWidgetInfo** to track the current state of our active widgets. Add the *inCustomization* field, which will be used to track when the widget host is expecting us to send our customization json template rather than the regular widget template.

C#

```
// WidgetProvider.cs
public class CompactWidgetInfo
{
```

```
    public string widgetId { get; set; }
    public string widgetName { get; set; }
    public int customState = 0;
    public bool isActive = false;
    public bool inCustomization = false;
}
```

Implement IWidgetProvider2

The widget customization feature is exposed through the IWidgetProvider2 interface. Update the **WidgetProvider** class definition to implement this interface.

C#

```
// WidgetProvider.cs
internal class WidgetProvider : IWidgetProvider, IWidgetProvider2
```

Add an implementation for the OnCustomizationRequested callback of the **IWidgetProvider2** interface. This method uses the same pattern as the other callbacks we have used. We get the ID for the widget to be customized from the **WidgetContext** and find the **CompactWidgetInfo** helper struct associated with that widget and set the **inCustomization** field to true.

C#

```
// WidgetProvider.cs
public void OnCustomizationRequested(WidgetCustomizationRequestedArgs
customizationInvokedArgs)
{
    var widgetId = customizationInvokedArgs.WidgetContext.Id;
    if (RunningWidgets.ContainsKey(widgetId))
    {
        var localWidgetInfo = RunningWidgets[widgetId];
        localWidgetInfo.inCustomization = true;
        UpdateWidget(localWidgetInfo);
    }
}
```

Now, declare a string variable that defines the JSON template for the widget customization UI. For this example, we have a "Reset counter" button and an "Exit customization" button that will signal our provider to return to regular widget behavior. Place this definition next to the other template definitions.

C#

```
// WidgetProvider.cs
const string countWidgetCustomizationTemplate = @"
{
    ""type"": ""AdaptiveCard"",
    ""actions"" : [
        {
            ""type"": ""Action.Execute"",
            ""title"" : ""Reset counter"",
            ""verb"": ""reset""
            },
            {
            ""type"": ""Action.Execute"",
            ""title"": ""Exit customization"",
            ""verb"": ""exitCustomization""
            }
    ],
    ""$schema"": ""http://adaptivecards.io/schemas/adaptive-card.json"",
    ""version"": ""1.5""
}";
```

Send customization template in UpdateWidget

Next, we'll update our **UpdateWidget** helper method that sends our data and visual JSON templates to the widget host. When we are updating the counting widget, we send either the regular widget template or the customization template depending on the value of the **inCustomization** field. For brevity, code not relevant to customization is omitted in this code snippet.

C#

```
// WidgetProvider.cs
void UpdateWidget(CompactWidgetInfo localWidgetInfo)
{
    ...
    else if (localWidgetInfo.widgetName == "Counting_Widget")
    {
        if (!localWidgetInfo.inCustomization)
        {
            templateJson = countWidgetTemplate.ToString();
        }
        else
        {
            templateJson = countWidgetCustomizationTemplate.ToString();
        }

    }
    ...
    updateOptions.Template = templateJson;
    updateOptions.Data = dataJson;
    // You can store some custom state in the widget service that you will
```

```
be able to query at any time.
    updateOptions.CustomState = localWidgetInfo.customState.ToString();
    WidgetManager.GetDefault().UpdateWidget(updateOptions);
}
```

Respond to customization actions

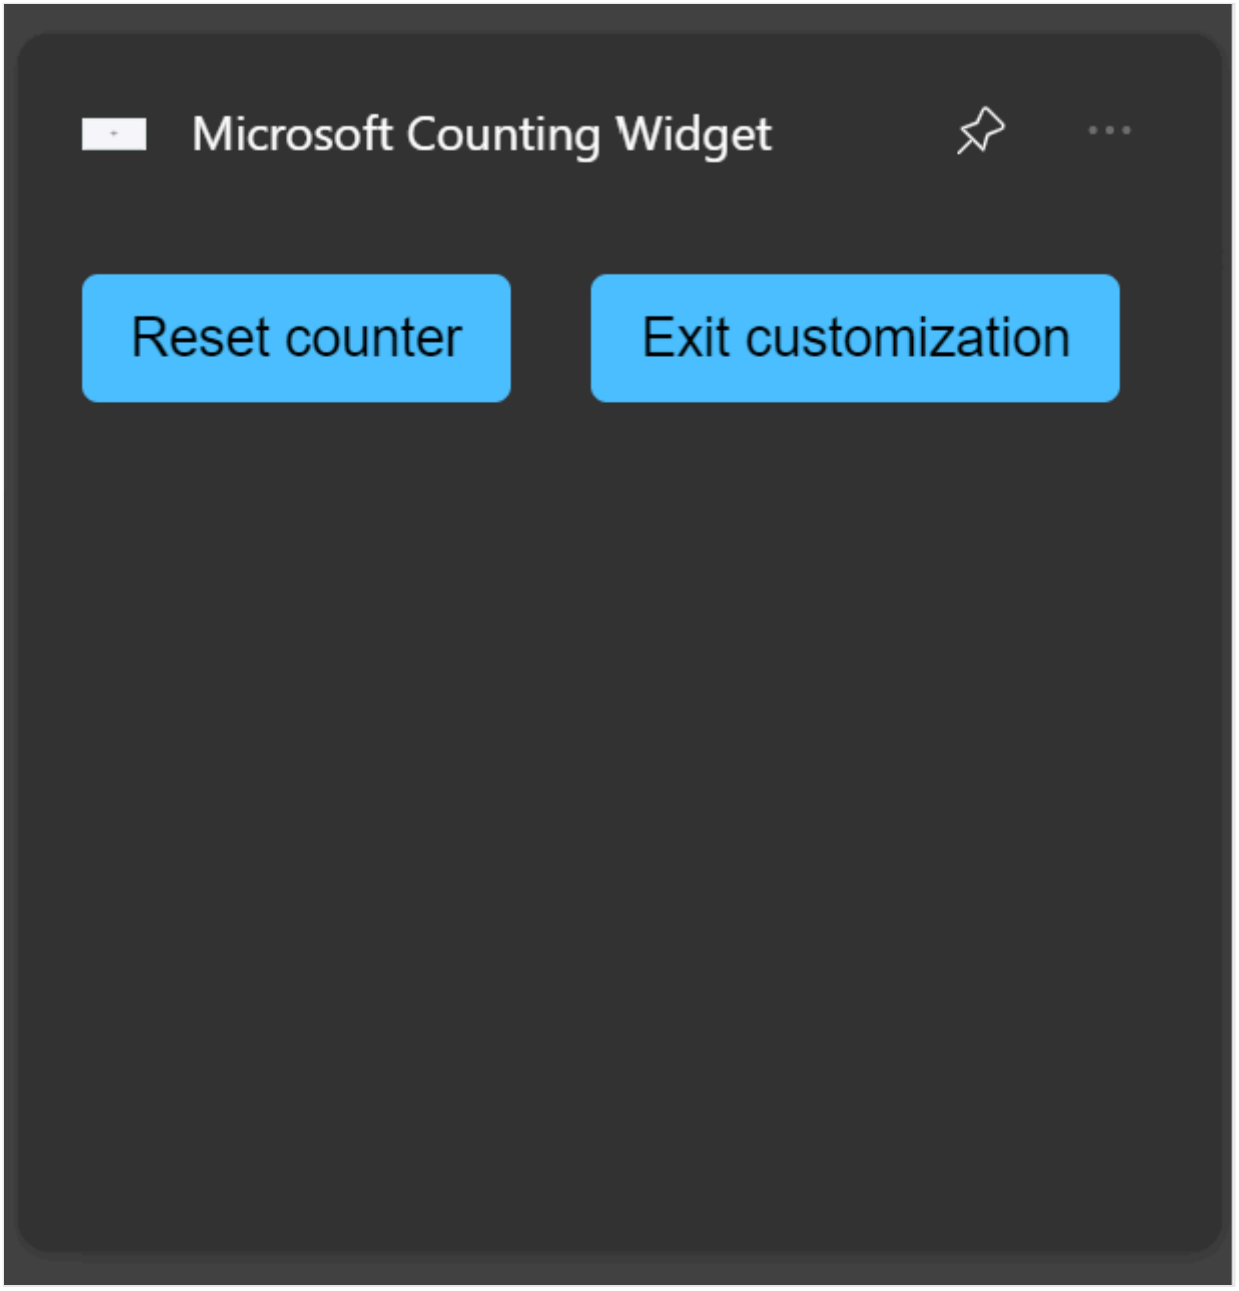
When users interact with inputs in our customization template, it calls the same **OnActionInvoked** handler as when the user interacts with the regular widget experience. To support customization, we look for the verbs "reset" and "exitCustomization" from our customization JSON template. If the action is for the "Reset counter" button, we reset the counter held in the **customState** field of our helper struct to 0. If the action is for the "Exit customization" button, we set the **inCustomization** field to false so that when we call **UpdateWidget**, our helper method will send the regular JSON templates and not the customization template.

C#

```
// WidgetProvider.cs
public void OnActionInvoked(WidgetActionInvokedArgs actionInvokedArgs)
{
    var verb = actionInvokedArgs.Verb;
    if (verb == "inc")
    {
        var widgetId = actionInvokedArgs.WidgetContext.Id;
        // If you need to use some data that was passed in after
        // Action was invoked, you can get it from the args:
        var data = actionInvokedArgs.Data;
        if (RunningWidgets.ContainsKey(widgetId))
        {
            var localWidgetInfo = RunningWidgets[widgetId];
            // Increment the count
            localWidgetInfo.customState++;
            UpdateWidget(localWidgetInfo);
        }
    }
    else if (verb == "reset")
    {
        var widgetId = actionInvokedArgs.WidgetContext.Id;
        var data = actionInvokedArgs.Data;
        if (RunningWidgets.ContainsKey(widgetId))
        {
            var localWidgetInfo = RunningWidgets[widgetId];
            // Reset the count
            localWidgetInfo.customState = 0;
            localWidgetInfo.inCustomization = false;
            UpdateWidget(localWidgetInfo);
        }
    }
```

```
    else if (verb == "exitCustomization")
    {
        var widgetId = actionInvokedArgs.WidgetContext.Id;
        var data = actionInvokedArgs.Data;
        if (RunningWidgets.ContainsKey(widgetId))
        {
            var localWidgetInfo = RunningWidgets[widgetId];
            // Stop sending the customization template
            localWidgetInfo.inCustomization = false;
            UpdateWidget(localWidgetInfo);
        }
    }
}
```

Now, when you deploy your widget, you should see the **Customize widget** button in the ellipses menu. Clicking on the customize button will display your customization template.

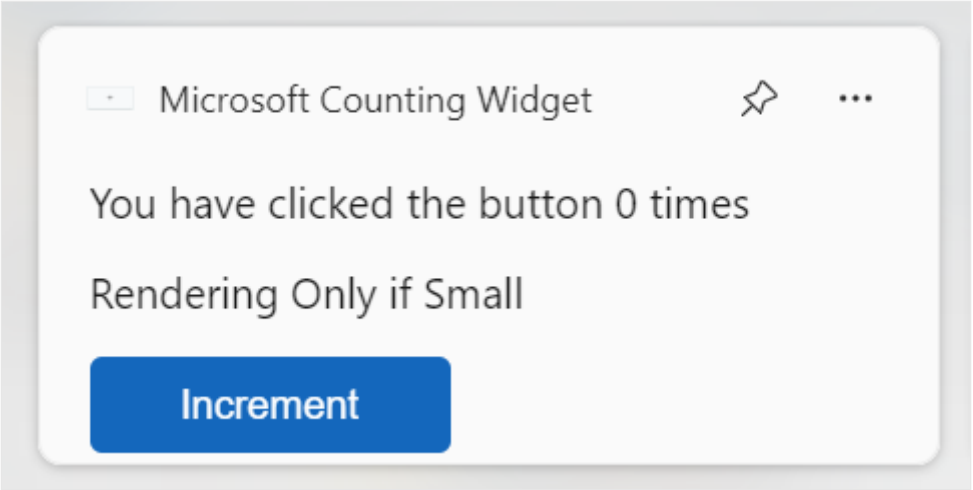


Click the **Reset counter** button to reset the counter to 0. Click the **Exit customization** button to return to your widget's regular behavior.

Implement a widget provider in a win32 app (C++/WinRT)

Article • 10/02/2023

This article walks you through creating a simple widget provider that implements the IWidgetProvider interface. The methods of this interface are invoked by the widget host to request the data that defines a widget or to let the widget provider respond to a user action on a widget. Widget providers can support a single widget or multiple widgets. In this example, we will define two different widgets. One widget is a mock weather widget that illustrates some of the formatting options provided by the Adaptive Cards framework. The second widget will demonstrate user actions and the custom widget state feature by maintaining a counter that is incremented whenever the user clicks on a button displayed on the widget.



This sample code in this article is adapted from the Windows App SDK Widgets Sample. To implement a widget provider using C#, see Implement a widget provider in a win32 app (C#).

Prerequisites

- Your device must have developer mode enabled. For more information see Enable your device for development.
- Visual Studio 2022 or later with the **Universal Windows Platform development** workload. Make sure to add the component for C++ (v143) from the optional dropdown.

Create a new C++/WinRT win32 console app

In Visual Studio, create a new project. In the **Create a new project** dialog, set the language filter to "C++" and the platform filter to Windows, then select the Windows Console Application (C++/WinRT) project template. Name the new project "ExampleWidgetProvider". When prompted, set the target Windows version for the app to version 1809 or later.

Add references to the Windows App SDK and Windows Implementation Library NuGet packages

This sample uses the latest stable Windows App SDK NuGet package. In **Solution Explorer**, right-click **References** and select **Manage NuGet packages...**. In the NuGet package manager, select the **Browse** tab and search for "Microsoft.WindowsAppSDK". Select the latest stable version in the **Version** drop-down and then click **Install**.

This sample also uses the Windows Implementation Library NuGet package. In **Solution Explorer**, right-click **References** and select **Manage NuGet packages...**. In the NuGet package manager, select the **Browse** tab and search for "Microsoft.Windows.ImplementationLibrary". Select the latest version in the **Version** drop-down and then click **Install**.

In the precompiled header file, pch.h, add the following include directives.

C++

```
//pch.h
#pragma once
#include <wil/cppwinrt.h>
#include <wil/resource.h>
...
#include <winrt/Microsoft.Windows.Widgets.Providers.h>
```

> **Note**
>
> You must include the wil/cppwinrt.h header first, before any WinRT headers.

In order to handle shutting down the widget provider app correctly, we need to a custom implementation of **winrt::get_module_lock**. We pre-declare the **SignalLocalServerShutdown** method which will be defined in our main.cpp file and will set an event that signals the app to exit. Add the following code to your pch.h file, just below the `#pragma once` directive, before the other includes.

C++

```
//pch.h
#include <stdint.h>
#include <combaseapi.h>

// In .exe local servers the class object must not contribute to the module
ref count, and use
// winrt::no_module_lock, the other objects must and this is the hook into
the C++ WinRT ref counting system
// that enables this.
void SignalLocalServerShutdown();

namespace winrt
{
    inline auto get_module_lock() noexcept
    {
        struct service_lock
        {
            uint32_t operator++() noexcept
```

```
            {
                return ::CoAddRefServerProcess();
            }

            uint32_t operator--() noexcept
            {
                const auto ref = ::CoReleaseServerProcess();

                if (ref == 0)
                {
                    SignalLocalServerShutdown();
                }
                return ref;
            }
        };

        return service_lock{};
    }
}

#define WINRT_CUSTOM_MODULE_LOCK
```

Add a WidgetProvider class to handle widget operations

In Visual Studio, right-click the `ExampleWidgetProvider` project in **Solution Explorer** and select **Add->Class**. In the **Add class** dialog, name the class "WidgetProvider" and click **Add**.

Declare a class that implements the IWidgetProvider interface

The **IWidgetProvider** interface defines methods that the widget host will invoke to initiate operations with the widget provider. Replace the empty class definition in the WidgetProvider.h file with the following code. This code declares a structure that implements the **IWidgetProvider** interface and declares prototypes for the interface methods.

C++

```
// WidgetProvider.h
struct WidgetProvider : winrt::implements<WidgetProvider,
winrt::Microsoft::Windows::Widgets::Providers::IWidgetProvider>
{
    WidgetProvider();
```

```
    /* IWidgetProvider required functions that need to be implemented */
    void
CreateWidget(winrt::Microsoft::Windows::Widgets::Providers::WidgetContext
widgetContext);
    void DeleteWidget(winrt::hstring const& widgetId, winrt::hstring const&
customState);
    void
OnActionInvoked(winrt::Microsoft::Windows::Widgets::Providers::WidgetActionI
nvokedArgs actionInvokedArgs);
    void
OnWidgetContextChanged(winrt::Microsoft::Windows::Widgets::Providers::Widget
ContextChangedArgs contextChangedArgs);
    void
Activate(winrt::Microsoft::Windows::Widgets::Providers::WidgetContext
widgetContext);
    void Deactivate(winrt::hstring widgetId);
    /* IWidgetProvider required functions that need to be implemented */

};
```

Also, add a private method, **UpdateWidget**, which is a helper method that will send updates from our provider to the widget host.

C++

```
// WidgetProvider.h
private:

void UpdateWidget(CompactWidgetInfo const& localWidgetInfo);
```

Prepare to track enabled widgets

A widget provider can support a single widget or multiple widgets. Whenever the widget host initiates an operation with the widget provider, it passes an ID to identify the widget associated with the operation. Each widget also has an associated name and a state value that can be used to store custom data. For this example, we'll declare a simple helper structure to store the ID, name, and data for each pinned widget. Widgets also can be in an active state, which is discussed in the Activate and Deactivate section below, and we will track this state for each widget with a boolean value. Add the following definition to the WidgetProvider.h file, above the **WidgetProvider** struct declaration.

C++

```
// WidgetProvider.h
struct CompactWidgetInfo
{
    winrt::hstring widgetId;
    winrt::hstring widgetName;
    int customState = 0;
    bool isActive = false;
};
```

Inside the **WidgetProvider** declaration in WidgetProvider.h, add a member for the map that will maintain the list of enabled widgets, using the widget ID as the key for each entry.

C++

```
// WidgetProvider.h
#include <unordered_map>
struct WidgetProvider : winrt::implements<WidgetProvider,
winrt::Microsoft::Windows::Widgets::Providers::IWidgetProvider>
{
...
    private:
        ...
        static std::unordered_map<winrt::hstring, CompactWidgetInfo>
RunningWidgets;
```

Declare widget template JSON strings

This example will declare some static strings to define the JSON templates for each widget. For convenience, these templates are stored in the local variables declared outside of the **WidgetProvider** class definition. If you need a general storage for the templates - they can be included as part of the application package: Accessing Package Files. For information on creating the widget template JSON document, see Create a widget template with the Adaptive Card Designer.

In the latest release, apps that implement Windows widgets can customize the header that is displayed for their widget in the Widgets Board, overriding the default presentation. For more information, see Customize the widget header area.

> **Note**
>
> Starting with Windows Build [TBD - Build number], apps that implement Windows widgets can choose to populate the widget content with HTML served from a

specified URL instead of supplying content in the Adaptive Card schema format in the JSON payload passed from the provider to the Widgets Board. Widget providers must still provide an Adaptive Card JSON payload, so the implementation steps in this walkthrough are applicable to web widgets. For more information, see Web widget providers.

C++

```
// WidgetProvider.h
const std::string weatherWidgetTemplate = R"(
{
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "type": "AdaptiveCard",

        }
    ],
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.5"
})";
```

Implement the IWidgetProvider methods

In the next few sections, we'll implement the methods of the **IWidgetProvider** interface. The helper method **UpdateWidget** that is called in several of these method implementations will be shown later in this article. Before diving into the interface methods, add the following lines to `WidgetProvider.cpp`, after the include directives, to pull the widget provider APIs into the **winrt** namespace and allow access to the map we declared in the previous step.

> ⓘ **Note**
>
> Objects passed into the callback methods of the **IWidgetProvider** interface are only guaranteed to be valid within the callback. You should not store references to these objects because their behavior outside of the context of the callback is undefined.

C++

```
// WidgetProvider.cpp
namespace winrt
```

```
{
    using namespace Microsoft::Windows::Widgets::Providers;
}

std::unordered_map<winrt::hstring, CompactWidgetInfo>
WidgetProvider::RunningWidgets{};
```

CreateWidget

The widget host calls CreateWidget when the user has pinned one of your app's widgets in the widget host. First, this method gets the ID and name of the associated widget and adds a new instance of our helper structure, **CompactWidgetInfo**, to the collection of enabled widgets. Next, we send the initial template and data for the widget, which is encapsulated in the **UpdateWidget** helper method.

C++

```
// WidgetProvider.cpp
void WidgetProvider::CreateWidget(winrt::WidgetContext widgetContext)
{
    auto widgetId = widgetContext.Id();
    auto widgetName = widgetContext.DefinitionId();
    CompactWidgetInfo runningWidgetInfo{ widgetId, widgetName };
    RunningWidgets[widgetId] = runningWidgetInfo;

    // Update the widget
    UpdateWidget(runningWidgetInfo);
}
```

DeleteWidget

The widget host calls DeleteWidget when the user has unpinned one of your app's widgets from the widget host. When this occurs, we will remove the associated widget from our list of enabled widgets so that we don't send any further updates for that widget.

C++

```
// WidgetProvider.cpp
void WidgetProvider::DeleteWidget(winrt::hstring const& widgetId,
winrt::hstring const& customState)
{
    RunningWidgets.erase(widgetId);
}
```

OnActionInvoked

The widget host calls OnActionInvoked when the user interacts with an action you defined in your widget template. For the counter widget used in this example, an action was declared with a **verb** value of "inc" in the JSON template for the widget. The widget provider code will use this **verb** value to determine what action to take in response to the user interaction.

JSON

```
...
    "actions": [
        {
            "type": "Action.Execute",
            "title": "Increment",
            "verb": "inc"
        }
    ],
...
```

In the **OnActionInvoked** method, get the verb value by checking the **Verb** property of the WidgetActionInvokedArgs passed into the method. If the verb is "inc", then we know we are going to increment the count in the custom state for the widget. From the **WidgetActionInvokedArgs**, get the WidgetContext object and then the **WidgetId** to get the ID for the widget that is being updated. Find the entry in our enabled widgets map with the specified ID and then update the custom state value that is used to store the number of increments. Finally, update the widget content with the new value with the **UpdateWidget** helper function.

C++

```
// WidgetProvider.cpp
void WidgetProvider::OnActionInvoked(winrt::WidgetActionInvokedArgs
actionInvokedArgs)
{
    auto verb = actionInvokedArgs.Verb();
    if (verb == L"inc")
    {
        auto widgetId = actionInvokedArgs.WidgetContext().Id();
        // If you need to use some data that was passed in after
        // Action was invoked, you can get it from the args:
        auto data = actionInvokedArgs.Data();
        if (const auto iter = RunningWidgets.find(widgetId); iter !=
RunningWidgets.end())
        {
            auto& localWidgetInfo = iter->second;
            // Increment the count
            localWidgetInfo.customState++;
```

```
            UpdateWidget(localWidgetInfo);
        }
    }
}
```

For information about the **Action.Execute** syntax for Adaptive Cards, see Action.Execute. For guidance about designing interaction for widgets, see Widget interaction design guidance

OnWidgetContextChanged

In the current release, OnWidgetContextChanged is only called when the user changes the size of a pinned widget. You can choose to return a different JSON template/data to the widget host depending on what size is requested. You can also design the template JSON to support all the available sizes using conditional rendering based on the value of **host.widgetSize**. If you don't need to send a new template or data to account for the size change, you can use the **OnWidgetContextChanged** for telemetry purposes.

C++

```
// WidgetProvider.cpp
void WidgetProvider::OnWidgetContextChanged(winrt::WidgetContextChangedArgs
contextChangedArgs)
{
    auto widgetContext = contextChangedArgs.WidgetContext();
    auto widgetId = widgetContext.Id();
    auto widgetSize = widgetContext.Size();
    if (const auto iter = RunningWidgets.find(widgetId); iter !=
RunningWidgets.end())
    {
        auto localWidgetInfo = iter->second;

        UpdateWidget(localWidgetInfo);
    }
}
```

Activate and Deactivate

The Activate method is called to notify the widget provider that the widget host is currently interested in receiving updated content from the provider. For example, it could mean that the user is currently actively viewing the widget host. The Deactivate method is called to notify the widget provider that the widget host is no longer requesting content updates. These two methods define a window in which the widget host is most interested in showing the most up-to-date content. Widget providers can

send updates to the widget at any time, such as in response to a push notification, but as with any background task, it's important to balance providing up-to-date content with resource concerns like battery life.

Activate and **Deactivate** are called on a per-widget basis. This example tracks the active status of each widget in the **CompactWidgetInfo** helper struct. In the **Activate** method, we call the **UpdateWidget** helper method to update our widget. Note that the time window between **Activate** and **Deactivate** may be small, so it's recommended that you try to make your widget update code path as quick as possible.

C++

```
void
WidgetProvider::Activate(winrt::Microsoft::Windows::Widgets::Providers::Widg
etContext widgetContext)
{
    auto widgetId = widgetContext.Id();

    if (const auto iter = RunningWidgets.find(widgetId); iter !=
RunningWidgets.end())
    {
        auto& localWidgetInfo = iter->second;
        localWidgetInfo.isActive = true;

        UpdateWidget(localWidgetInfo);
    }
}

void WidgetProvider::Deactivate(winrt::hstring widgetId)
{
    if (const auto iter = RunningWidgets.find(widgetId); iter !=
RunningWidgets.end())
    {
        auto& localWidgetInfo = iter->second;
        localWidgetInfo.isActive = false;
    }
}
```

Update a widget

Define the **UpdateWidget** helper method to update an enabled widget. In this example, we check the name of the widget in the **CompactWidgetInfo** helper struct passed into the method, and then set the appropriate template and data JSON based on which widget is being updated. A **WidgetUpdateRequestOptions** is initialized with the template, data, and custom state for the widget being updated. Call WidgetManager::GetDefault to get an instance of the WidgetManager class and then call UpdateWidget to send the updated widget data to the widget host.

C++

```
// WidgetProvider.cpp
void WidgetProvider::UpdateWidget(CompactWidgetInfo const& localWidgetInfo)
{
    winrt::WidgetUpdateRequestOptions updateOptions{
localWidgetInfo.widgetId };

    winrt::hstring templateJson;
    if (localWidgetInfo.widgetName == L"Weather_Widget")
    {
        templateJson = winrt::to_hstring(weatherWidgetTemplate);
    }
    else if (localWidgetInfo.widgetName == L"Counting_Widget")
    {
        templateJson = winrt::to_hstring(countWidgetTemplate);
    }

    winrt::hstring dataJson;
    if (localWidgetInfo.widgetName == L"Weather_Widget")
    {
        dataJson = L"{}";
    }
    else if (localWidgetInfo.widgetName == L"Counting_Widget")
    {
        dataJson = L"{ \"count\": " +
winrt::to_hstring(localWidgetInfo.customState) + L" }";
    }

    updateOptions.Template(templateJson);
    updateOptions.Data(dataJson);
    // You can store some custom state in the widget service that you will
be able to query at any time.

updateOptions.CustomState(winrt::to_hstring(localWidgetInfo.customState));
    winrt::WidgetManager::GetDefault().UpdateWidget(updateOptions);
}
```

Initialize the list of enabled widgets on startup

When our widget provider is first initialized, it's a good idea to ask **WidgetManager** if there are any running widgets that our provider is currently serving. It will help to recover the app to the previous state in case of the computer restart or the provider crash. Call **WidgetManager::GetDefault** to get the default widget manager instance for the app. Then call GetWidgetInfos, which returns an array of WidgetInfo objects. Copy the widget IDs, names, and custom state into the helper struct **CompactWidgetInfo** and save it to the **RunningWidgets** member variable. Paste the following code into the constructor for the **WidgetProvider** class.

C++

```
// WidgetProvider.cpp
WidgetProvider::WidgetProvider()
{
    auto runningWidgets =
winrt::WidgetManager::GetDefault().GetWidgetInfos();
    for (auto widgetInfo : runningWidgets )
    {
        auto widgetContext = widgetInfo.WidgetContext();
        auto widgetId = widgetContext.Id();
        auto widgetName = widgetContext.DefinitionId();
        auto customState = widgetInfo.CustomState();
        if (RunningWidgets.find(widgetId) == RunningWidgets.end())
        {
            CompactWidgetInfo runningWidgetInfo{ widgetId, widgetName };
            try
            {
                // If we had any save state (in this case we might have some
state saved for Counting widget)
                // convert string to required type if needed.
                int count = std::stoi(winrt::to_string(customState));
                runningWidgetInfo.customState = count;
            }
            catch (...)
            {

            }
            RunningWidgets[widgetId] = runningWidgetInfo;
        }
    }
}
```

Register a class factory that will instantiate WidgetProvider on request

Add the header that defines the **WidgetProvider** class to the includes at the top of your app's `main.cpp` file. We will also be including **mutex** here.

C++

```
// main.cpp
...
#include "WidgetProvider.h"
#include <mutex>
```

Declare the event that will trigger our app to exit and the **SignalLocalServerShutdown** function that will set the event. Paste the following code in main.cpp.

C++

```
// main.cpp
wil::unique_event g_shudownEvent(wil::EventOptions::None);

void SignalLocalServerShutdown()
{
    g_shudownEvent.SetEvent();
}
```

Next, you will need to create a CLSID that will be used to identify your widget provider for COM activation. Generate a GUID in Visual Studio by going to **Tools->Create GUID**. Select the option "static const GUID =" and click **Copy** and then paste that into `main.cpp`. Update the GUID definition with the following C++/WinRT syntax, setting the GUID variable name widget_provider_clsid. Leave the commented version of the GUID because you will need this format later, when packaging your app.

C++

```
// main.cpp
...
// {80F4CB41-5758-4493-9180-4FB8D480E3F5}
static constexpr GUID widget_provider_clsid
{
    0x80f4cb41, 0x5758, 0x4493, { 0x91, 0x80, 0x4f, 0xb8, 0xd4, 0x80, 0xe3,
0xf5 }
};
```

Add the following class factory definition to `main.cpp`. This is mostly boilerplate code that is not specific to widget provider implementations. Note that **CoWaitForMultipleObjects** waits for our shutdown event to be triggered before the app exits.

C++

```
// main.cpp
template <typename T>
struct SingletonClassFactory : winrt::implements<SingletonClassFactory<T>,
IClassFactory>
{
    STDMETHODIMP CreateInstance(
        ::IUnknown* outer,
        GUID const& iid,
        void** result) noexcept final
    {
        *result = nullptr;

        std::unique_lock lock(mutex);
```

```
        if (outer)
        {
            return CLASS_E_NOAGGREGATION;
        }

        if (!instance)
        {
            instance = winrt::make<WidgetProvider>();
        }

        return instance.as(iid, result);
    }

    STDMETHODIMP LockServer(BOOL) noexcept final
    {
        return S_OK;
    }

private:
    T instance{ nullptr };
    std::mutex mutex;
};

int main()
{
    winrt::init_apartment();
    wil::unique_com_class_object_cookie widgetProviderFactory;
    auto factory =
winrt::make<SingletonClassFactory<winrt::Microsoft::Windows::Widgets::Provid
ers::IWidgetProvider>>();

    winrt::check_hresult(CoRegisterClassObject(
        widget_provider_clsid,
        factory.get(),
        CLSCTX_LOCAL_SERVER,
        REGCLS_MULTIPLEUSE,
        widgetProviderFactory.put()));

    DWORD index{};
    HANDLE events[] = { g_shudownEvent.get() };
    winrt::check_hresult(CoWaitForMultipleObjects(CWMO_DISPATCH_CALLS |
CWMO_DISPATCH_WINDOW_MESSAGES,
        INFINITE,
        static_cast<ULONG>(std::size(events)), events, &index));

    return 0;
}
```

Package your widget provider app

In the current release, only packaged apps can be registered as widget providers. The following steps will take you through the process of packaging your app and updating the app manifest to register your app with the OS as a widget provider.

Create an MSIX packaging project

In **Solution Explorer**, right-click your solution and select **Add->New Project...**. In the **Add a new project** dialog, select the "Windows Application Packaging Project" template and click **Next**. Set the project name to "ExampleWidgetProviderPackage" and click **Create**. When prompted, set the target version to version 1809 or later and click **OK**. Next, right-click the ExampleWidgetProviderPackage project and select **Add->Project reference**. Select the **ExampleWidgetProvider** project and click OK.

Add Windows App SDK package reference to the packaging project

You need to add a reference to the Windows App SDK nuget package to the MSIX packaging project. In **Solution Explorer**, double-click the ExampleWidgetProviderPackage project to open the ExampleWidgetProviderPackage.wapproj file. Add the following xml inside the **Project** element.

XML

```
<!--ExampleWidgetProviderPackage.wapproj-->
<ItemGroup>
    <PackageReference Include="Microsoft.WindowsAppSDK"
Version="1.2.221116.1">
        <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

> **Note**
>
> Make sure the **Version** specified in the **PackageReference** element matches the latest stable version you referenced in the previous step.

If the correct version of the Windows App SDK is already installed on the computer and you don't want to bundle the SDK runtime in your package, you can specify the package dependency in the Package.appxmanifest file for the ExampleWidgetProviderPackage project.

XML

```
<!--Package.appxmanifest-->
...
<Dependencies>
...
    <PackageDependency Name="Microsoft.WindowsAppRuntime.1.2-preview2"
MinVersion="2000.638.7.0" Publisher="CN=Microsoft Corporation, O=Microsoft
Corporation, L=Redmond, S=Washington, C=US" />
...
</Dependencies>
...
```

Update the package manifest

In **Solution Explorer** right-click the `Package.appxmanifest` file and select **View Code** to open the manifest xml file. Next you need to add some namespace declarations for the app package extensions we will be using. Add the following namespace definitions to the top-level Package element.

XML

```
<!-- Package.appmanifest -->
<Package
  ...
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"
```

Inside the **Application** element, create a new empty element named **Extensions**. Make sure this comes after the closing tag for **uap:VisualElements**.

XML

```
<!-- Package.appxmanifest -->
<Application>
...
    <Extensions>

    </Extensions>
</Application>
```

The first extension we need to add is the ComServer extension. This registers the entry point of the executable with the OS. This extension is the packaged app equivalent of registering a COM server by setting a registry key, and is not specific to widget providers.Add the following **com:Extension** element as a child of the **Extensions**

element. Change the GUID in the **Id** attribute of the **com:Class** element to the GUID you generated in a previous step.

XML

```
<!-- Package.appxmanifest -->
<Extensions>
    <com:Extension Category="windows.comServer">
        <com:ComServer>
            <com:ExeServer
Executable="ExampleWidgetProvider\ExampleWidgetProvider.exe"
DisplayName="ExampleWidgetProvider">
                <com:Class Id="xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"
DisplayName="ExampleWidgetProvider" />
            </com:ExeServer>
        </com:ComServer>
    </com:Extension>
</Extensions>
```

Next, add the extension that registers the app as a widget provider. Paste the uap3:Extension element in the following code snippet, as a child of the **Extensions** element. Be sure to replace the **ClassId** attribute of the **COM** element with the GUID you used in previous steps.

XML

```
<!-- Package.appxmanifest -->
<Extensions>
    ...
    <uap3:Extension Category="windows.appExtension">
        <uap3:AppExtension Name="com.microsoft.windows.widgets"
DisplayName="WidgetTestApp" Id="ContosoWidgetApp" PublicFolder="Public">
            <uap3:Properties>
                <WidgetProvider>
                    <ProviderIcons>
                        <Icon Path="Images\StoreLogo.png" />
                    </ProviderIcons>
                    <Activation>
                        <!-- Apps exports COM interface which implements
IWidgetProvider -->
                        <CreateInstance ClassId="xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx" />
                    </Activation>

                    <TrustedPackageFamilyNames>

<TrustedPackageFamilyName>Microsoft.MicrosoftEdge.Stable_8wekyb3d8bbwe</Trus
tedPackageFamilyName>
                    </TrustedPackageFamilyNames>

                    <Definitions>
```

```
                        <Definition Id="Weather_Widget"
                            DisplayName="Weather Widget"
                            Description="Weather Widget Description"
                            AllowMultiple="true">
                            <Capabilities>
                                <Capability>
                                    <Size Name="small" />
                                </Capability>
                                <Capability>
                                    <Size Name="medium" />
                                </Capability>
                                <Capability>
                                    <Size Name="large" />
                                </Capability>
                            </Capabilities>
                            <ThemeResources>
                                <Icons>
                                    <Icon
Path="ProviderAssets\Weather_Icon.png" />
                                </Icons>
                                <Screenshots>
                                    <Screenshot
Path="ProviderAssets\Weather_Screenshot.png" DisplayAltText="For
accessibility" />
                                </Screenshots>
                                <!-- DarkMode and LightMode are optional -->
                                <DarkMode />
                                <LightMode />
                            </ThemeResources>
                        </Definition>
                        <Definition Id="Counting_Widget"
                                DisplayName="Microsoft Counting Widget"
                                Description="Couting Widget Description">
                            <Capabilities>
                                <Capability>
                                    <Size Name="small" />
                                </Capability>
                            </Capabilities>
                            <ThemeResources>
                                <Icons>
                                    <Icon
Path="ProviderAssets\Counting_Icon.png" />
                                </Icons>
                                <Screenshots>
                                    <Screenshot
Path="ProviderAssets\Counting_Screenshot.png" DisplayAltText="For
accessibility" />
                                </Screenshots>
                                <!-- DarkMode and LightMode are optional -->
                                <DarkMode>

                                </DarkMode>
                                <LightMode />
                            </ThemeResources>
                        </Definition>
```

```
                    </Definitions>
                </WidgetProvider>
            </uap3:Properties>
        </uap3:AppExtension>
    </uap3:Extension>
</Extensions>
```

For detailed descriptions and format information for all of these elements, see Widget provider package manifest XML format.

Add icons and other images to your packaging project

In **Solution Explorer**, right-click your **ExampleWidgetProviderPackage** and select **Add->New Folder**. Name this folder ProviderAssets as this is what was used in the `Package.appxmanifest` from the previous step. This is where we will store our **Icons** and **Screenshots** for our widgets. Once you add your desired Icons and Screenshots, make sure the image names match what comes after **Path=ProviderAssets** in your `Package.appxmanifest` or the widgets will not show up in the widget host.

For information about the design requirements for screenshot images and the naming conventions for localized screenshots, see Integrate with the widget picker.

Testing your widget provider

Make sure you have selected the architecture that matches your development machine from the **Solution Platforms** drop-down, for example "x64". In **Solution Explorer**, right-click your solution and select **Build Solution**. Once this is done, right-click your **ExampleWidgetProviderPackage** and select **Deploy**. In the current release, the only supported widget host is the Widgets Board. To see the widgets you will need to open the Widgets Board and select **Add widgets** in the top right. Scroll to the bottom of the available widgets and you should see the mock **Weather Widget** and **Microsoft Counting Widget** that were created in this tutorial. Click on the widgets to pin them to your widgets board and test their functionality.

Debugging your widget provider

After you have pinned your widgets, the Widget Platform will start your widget provider application in order to receive and send relevant information about the widget. To debug the running widget you can either attach a debugger to the running widget

provider application or you can set up Visual Studio to automatically start debugging the widget provider process once it's started.

In order to attach to the running process:

1. In Visual Studio click **Debug -> Attach to process**.
2. Filter the processes and find your desired widget provider application.
3. Attach the debugger.

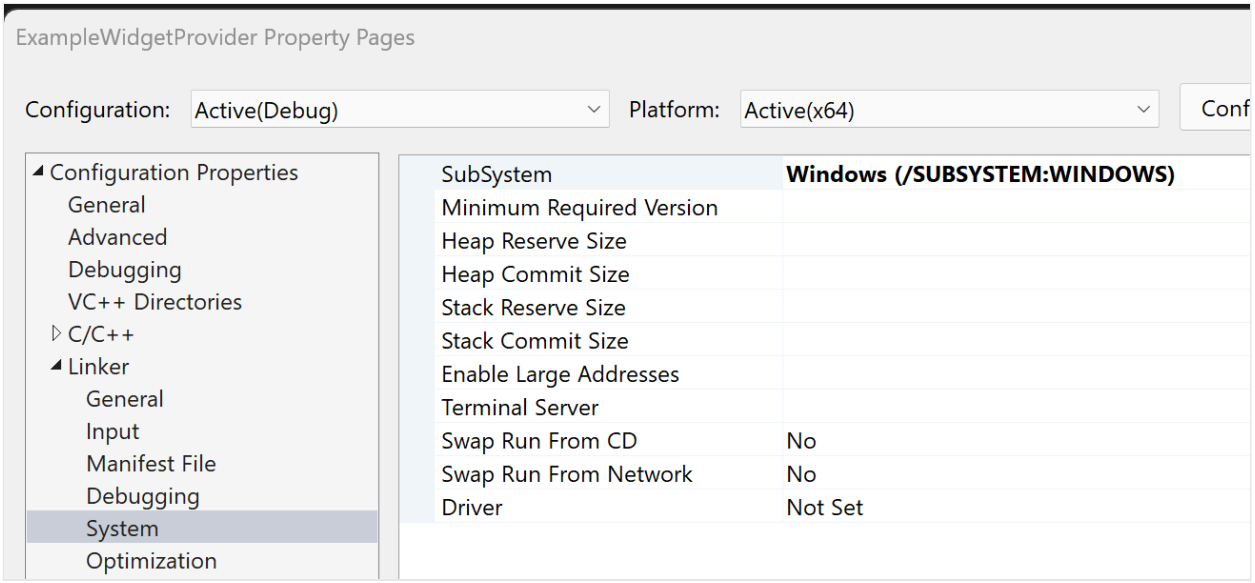
In order to automatically attach the debugger to the process when it's initially started:

1. In Visual Studio click **Debug -> Other Debug Targets -> Debug Installed App Package**.
2. Filter the packages and find your desired widget provider package.
3. Select it and check the box that says Do not launch, but debug my code when it starts.
4. Click **Attach**.

Convert your console app to a Windows app

To convert the console app created in this walkthrough to a Windows app:

1. Right-click on the ExampleWidgetProvider project in **Solution Explorer** and select **Properties**. Navigate to **Linker -> System** and change **SubSystem** from "Console" to "Windows". This can also be done by adding <SubSystem>Windows</SubSystem> to the <Link>..</Link> section of the .vcxproj.
2. In main.cpp, change `int main()` to `int WINAPI wWinMain(_In_ HINSTANCE /*hInstance*/, _In_opt_ HINSTANCE /*hPrevInstance*/, _In_ PWSTR pCmdLine, _In_ int /*nCmdShow*/)`.

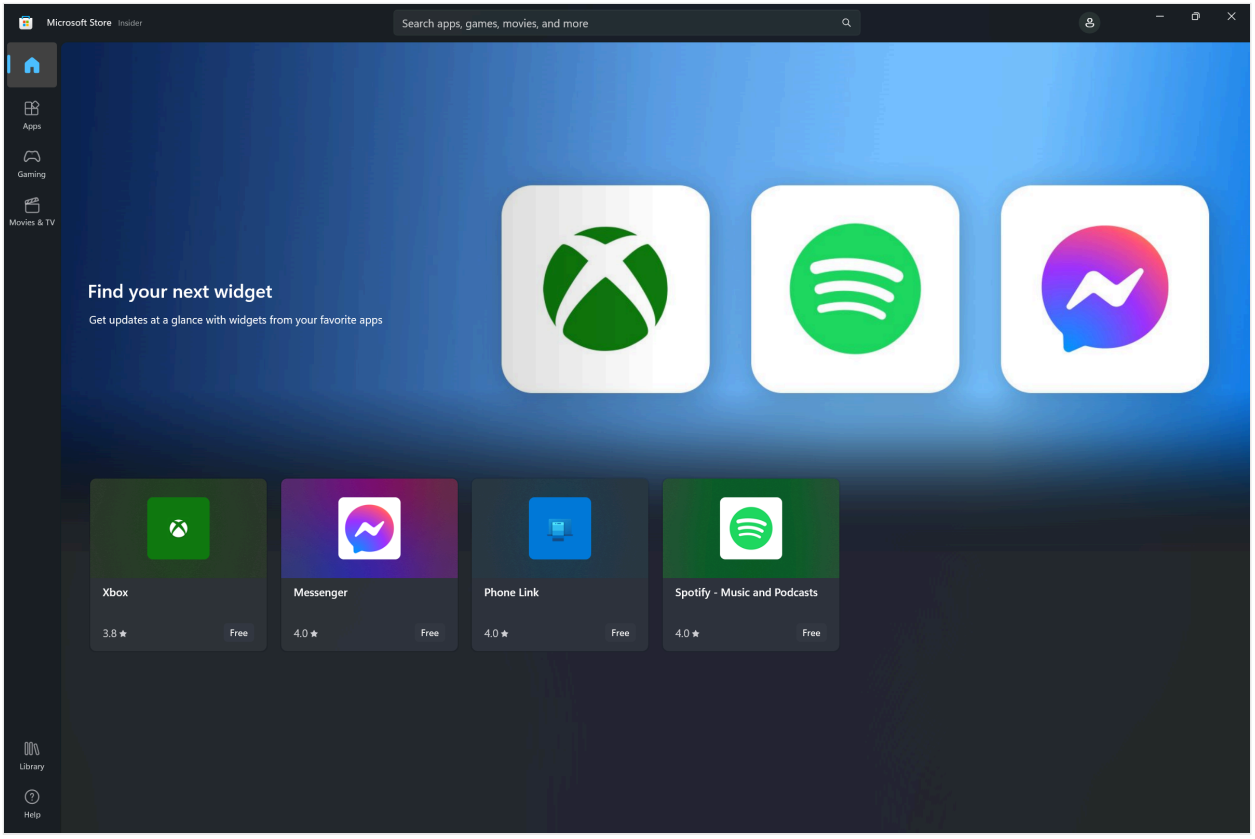


Publishing your widget

After you have developed and tested your widget you can publish your app on the Microsoft Store in order for users to install your widgets on their devices. For step by step guidance for publishing an app, see Publish your app in the Microsoft Store.

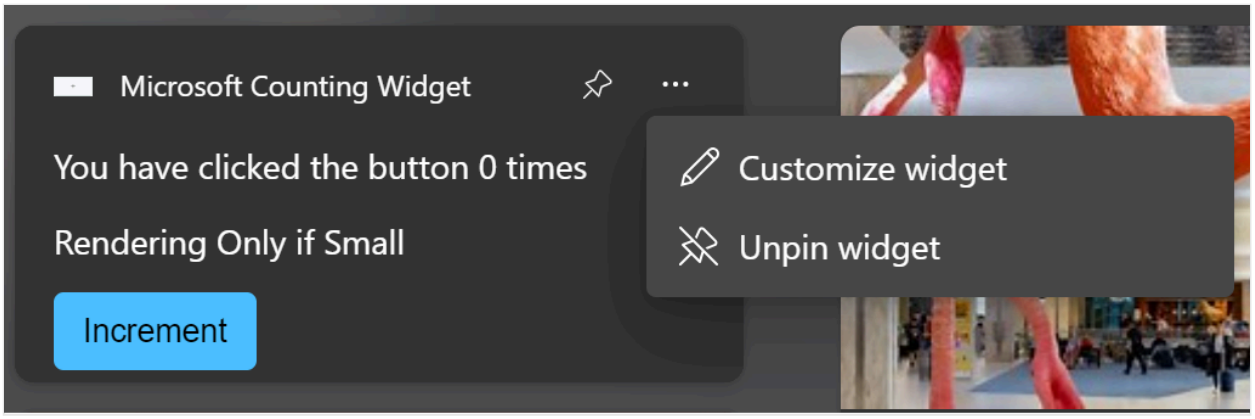
The widgets Store Collection

After your app has been published on the Microsoft Store, you can request for your app to be included in the widgets Store Collection that helps users discover apps that feature Windows Widgets. To submit your request, see Submit your Widget information for addition to the Store Collection .



Implementing widget customization

Starting with Windows App SDK 1.4, widgets can support user customization. When this feature is implemented, a **Customize widget** option is added to the ellipsis menu above the **Unpin widget** option.



The following steps summarize the process for widget customization.

1. In normal operation, the widget provider responds to requests from the widget host with the visual and data JSON templates for the regular widget experience.
2. The user clicks the **Customize widget** button in the ellipsis menu.
3. The widget raises the **OnCustomizationRequested** event on the widget provider to indicate that the user has requested the widget customization experience.
4. The widget provider sets an internal flag to indicate that the widget is in customization mode. While in customization mode, the widget provider sends the JSON templates for the widget customization UI instead of the regular widget UI.
5. While in customization mode, the widget provider receives **OnActionInvoked** events as the user interacts with the customization UI and adjusts its internal configuration and behavior based on the user's actions.
6. When the action associated with the **OnActionInvoked** event is the app-defined "exit customization" action, the widget provider resets it's internal flag to indicate that it is no longer in customization mode and resumes sending the visual and data JSON templates for the regular widget experience, reflecting the changes requested during customization.
7. The widget provider persists the customization options to disk or the cloud so that the changes are preserved between invocations of the widget provider.

> ⓘ **Note**
>
> There is a known bug with the Windows Widget Board, for widgets built using the Windows App SDK, that causes the ellipsis menu to become unresponsive after the customization card is shown.

In typical Widget customization scenarios, the user will choose what data is displayed on the widget or adjust visual presentation of the widget. For simplicity, the example in this section will add customization behavior that allows the user to reset the counter of the counting widget implemented in the previous steps.

> **Note**
>
> Widget customization is only supported in Windows App SDK 1.4 and later. Make sure you update the references in your project to the latest version of the Nuget package.

Update the package manifest to declare customization support

To let the widget host know that the widget supports customization, add the attribute **IsCustomizable** to the **Definition** eleent for the widget and set it to true.

XML

```
...
<Definition Id="Counting_Widget"
    DisplayName="Microsoft Counting Widget"
    Description="CONFIG counting widget description"
    IsCustomizable="true">
...
```

Update WidgetProvider.h

To add customization support to the widget that was created in the previous steps in this article, we will need to update the header file for our widget provider, WidgetProvider.h.

First, update the **CompactWidgetInfo** definition. This helper struct helps us track the current state of our active widgets. Add the *inCustomization* field, which will be used to track when the widget host is expecting us to send our customization json template rather than the regular widget template.

C++

```
// WidgetProvider.h
struct CompactWidgetInfo
{
    winrt::hstring widgetId;
    winrt::hstring widgetName;
    int customState = 0;
    bool isActive = false;
    bool inCustomization = false;
};
```

Update the **WidgetProvider** declaration to implement the IWidgetProvider2 interface.

C++

```
// WidgetProvider.h

struct WidgetProvider : winrt::implements<WidgetProvider,
winrt::Microsoft::Windows::Widgets::Providers::IWidgetProvider,
winrt::Microsoft::Windows::Widgets::Providers::IWidgetProvider2>
```

Add a declaration for the OnCustomizationRequested callback of the **IWidgetProvider2** interface.

C++

```
// WidgetProvider.h

void
OnCustomizationRequested(winrt::Microsoft::Windows::Widgets::Providers::Widg
etCustomizationRequestedArgs args);
```

Finally, declare a string variable that defines the JSON template for the widget customization UI. For this example, we have a "Reset counter" button and an "Exit customization" button that will signal our provider to return to regular widget behavior.

C++

```
// WidgetProvider.h
const std::string countWidgetCustomizationTemplate = R"(
{
    "type": "AdaptiveCard",
    "actions" : [
        {
            "type": "Action.Execute",
            "title" : "Reset counter",
            "verb": "reset"
            },
            {
            "type": "Action.Execute",
            "title": "Exit customization",
            "verb": "exitCustomization"
            }
    ],
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.5"
})";
```

Update WidgetProvider.cpp

Now update the WidgetProvider.cpp file to implement the widget customization behavior. This method uses the same pattern as the other callbacks we have used. We get the ID for the widget to be customized from the **WidgetContext** and find the **CompactWidgetInfo** helper struct associated with that widget and set the **inCustomization** field to true.

C++

```
//WidgetProvider.cpp
void
WidgetProvider::OnCustomizationRequested(winrt::WidgetCustomizationRequested
Args args)
{
    auto widgetId = args.WidgetContext().Id();

    if (const auto iter = RunningWidgets.find(widgetId); iter !=
RunningWidgets.end())
    {
        auto& localWidgetInfo = iter->second;
        localWidgetInfo.inCustomization = true;

        UpdateWidget(localWidgetInfo);
    }
}
```

Next, we'll update our **UpdateWidget** helper method that sends our data and visual JSON templates to the widget host. When we are updating the counting widget, we send either the regular widget template or the customization template depending on the value of the **inCustomization** field. For brevity, code not relevant to customization is omitted in this code snippet.

C++

```
//WidgetProvider.cpp
void WidgetProvider::UpdateWidget(CompactWidgetInfo const& localWidgetInfo)
{
    ...
    else if (localWidgetInfo.widgetName == L"Counting_Widget")
    {
        if (!localWidgetInfo.inCustomization)
        {
            std::wcout << L" - not in customization " << std::endl;
            templateJson = winrt::to_hstring(countWidgetTemplate);
        }
        else
        {
            std::wcout << L" - in customization " << std::endl;
            templateJson =
winrt::to_hstring(countWidgetCustomizationTemplate);
        }
```

```
    }
    ...

    updateOptions.Template(templateJson);
    updateOptions.Data(dataJson);
    // !!  You can store some custom state in the widget service that you
will be able to query at any time.

updateOptions.CustomState(winrt::to_hstring(localWidgetInfo.customState));
    winrt::WidgetManager::GetDefault().UpdateWidget(updateOptions);
}
```

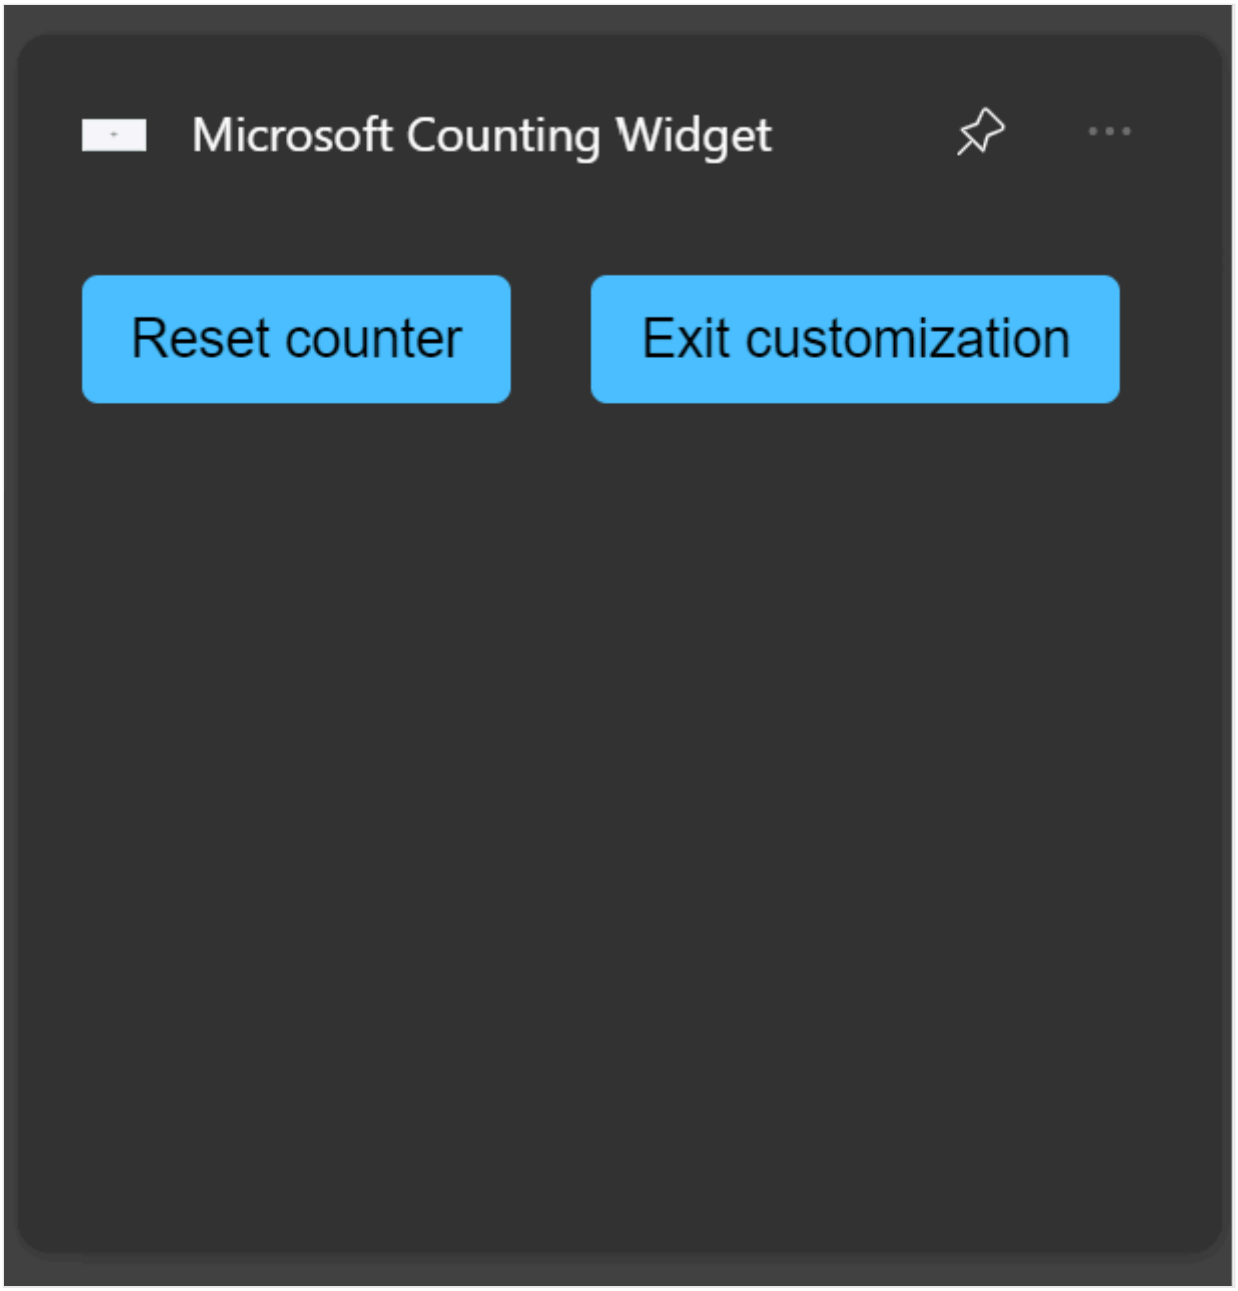
When users interact with inputs in our customization template, it calls the same **OnActionInvoked** handler as when the user interacts with the regular widget experience. To support customization, we look for the verbs "reset" and "exitCustomization" from our customization JSON template. If the action is for the "Reset counter" button, we reset the counter held in the **customState** field of our helper struct to 0. If the action is for the "Exit customization" button, we set the **inCustomization** field to false so that when we call **UpdateWidget**, our helper method will send the regular JSON templates and not the customization template.

C++

```
//WidgetProvider.cpp
void WidgetProvider::OnActionInvoked(winrt::WidgetActionInvokedArgs
actionInvokedArgs)
{
    auto verb = actionInvokedArgs.Verb();
    if (verb == L"inc")
    {
        auto widgetId = actionInvokedArgs.WidgetContext().Id();
        // If you need to use some data that was passed in after
        // Action was invoked, you can get it from the args:
        auto data = actionInvokedArgs.Data();
        if (const auto iter = RunningWidgets.find(widgetId); iter !=
RunningWidgets.end())
        {
            auto& localWidgetInfo = iter->second;
            // Increment the count
            localWidgetInfo.customState++;
            UpdateWidget(localWidgetInfo);
        }
    }
    else if (verb == L"reset")
    {
        auto widgetId = actionInvokedArgs.WidgetContext().Id();
        auto data = actionInvokedArgs.Data();
        if (const auto iter = RunningWidgets.find(widgetId); iter !=
RunningWidgets.end())
        {
            auto& localWidgetInfo = iter->second;
```

```
            // Reset the count
            localWidgetInfo.customState = 0;
            localWidgetInfo.inCustomization = false;
            UpdateWidget(localWidgetInfo);
        }
    }
    else if (verb == L"exitCustomization")
    {
        auto widgetId = actionInvokedArgs.WidgetContext().Id();
        // If you need to use some data that was passed in after
        // Action was invoked, you can get it from the args:
        auto data = actionInvokedArgs.Data();
        if (const auto iter = RunningWidgets.find(widgetId); iter !=
RunningWidgets.end())
        {
            auto& localWidgetInfo = iter->second;
            // Stop sending the customization template
            localWidgetInfo.inCustomization = false;
            UpdateWidget(localWidgetInfo);
        }
    }
}
```

Now, when you deploy your widget, you should see the **Customize widget** button in the ellipses menu. Clicking on the customize button will display your customization template.



Click the **Reset counter** button to reset the counter to 0. Click the **Exit customization** button to return to your widget's regular behavior.

Web widget providers

Article • 12/19/2024

In the latest release, apps that implement Windows widgets can choose to populate the widget content with HTML served from a remote URL. Previously, the widget content could only be supplied in the Adaptive Card schema format in the JSON payload passed from the provider to the Widgets Board. Because web widget providers must still provide an Adaptive Card JSON payload, you should follow the steps for implementing a widget provider in Implement a widget provider in a C# Windows App or Implement a widget provider in a win32 app (C++/WinRT).

Specify the content URL

Widget providers pass a JSON payload to the Widgets Board with a call to WidgetManager.UpdateWidget. For a web widget, instead of providing a **body** object defining the widget content, you should specify an empty **body** object and instead include a **metadata** object with a **webUrl** field that points to the URL that will supply the HTML content for the widget.

JSON

```
{
    "type": "AdaptiveCard",
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.6",
    "body": [],
    "metadata":
    {
        "webUrl": "https://www.contoso.com/widgetprovider.html"
    }
}
```

Handle resource requests

Widget providers can specify a web request filter string for a widget in the *WebRequestFilter* attribute of the **Definition** element in the provider's package manifest file. Whenever the widget content requests a resource by URI that matches the filter, the request will be intercepted and redirected to the widget provider's implementation of IWidgetResourceProvider.OnResourceRequested.

The filter pattern is expressed using the format described in Match Patterns. The filter string in the registration must use Punycode where necessary. All content types will be

redirected when matched so the filter should only resolve to content intended to be obtained through the **IWidgetResourceProvider** in the application. For more information on the widget provider package manifest format, see Widget provider package manifest XML format.

To handle resource requests, widget providers must implement the IWidgetResourceProvider interface.

C#

```
internal class WidgetProvider : IWidgetProvider, IWidgetResourceProvider
```

In the implementation of the **OnResourceRequested** method, widget providers can provide the requested resources by setting the WidgetResourceRequestedArgs.Response property to a WidgetResourceResponse object containing the requested resource. When obtaining the resource asynchronously, the provider should request a deferral by calling WidgetResourceRequestedArgs.GetDeferral and then complete the deferral when the resource has been set.

C#

```
async void
IWidgetResourceProvider.OnResourceRequested(WidgetResourceRequestedArgs
args)
{
    var deferral = args.GetDeferral();

    if (args.Request.Uri.Length > 0)
    {
        if (args.Request.Uri == "https://contoso.com/logo-image")
        {
            string fullPath =
Windows.ApplicationModel.Package.Current.InstalledPath +
"/Assets/image.png";
            var file = await StorageFile.GetFileFromPathAsync(fullPath);
            var response = new
WidgetResourceResponse(RandomAccessStreamReference.CreateFromFile(file),
"OK", 200);
            response.Headers.Add("Content-Type", "image/png");
            args.Response = response;
        }
    }

    deferral.Complete();
}
```

If the provider does not set a response on the **WidgetResourceRequestedArgs** object passed into the method, the system will retrieve the resource from the web. In this case, the provider can choose to modify the Headers property of the WidgetResourceRequestedArgs.Request object, such as to provide user context or tokens, and the system will use the updated headers when retrieving the resource from the web.

Handle messages to and from web content

To receive string messages from the widget's content that has been posted using the window.chrome.webview.postMessage JavaScript method, widget providers can implement the IWidgetProviderMessage interface and implement the OnMessageReceived method.

C#

```
internal class WidgetProvider : IWidgetProvider, IWidgetProviderMessage
...
public void OnMessageReceived(WidgetMessageReceivedArgs args)
{
    Console.WriteLine($"Message received from widget
{args.WidgetContext.Id}: {args.Message}");
}
```

Widget providers can send a message to the web content of the widget by calling WidgetManager.SendMessage. You must provide the ID of the widget to which the message is sent, which is the value specified in the *Id* attribute of the **Definition** element in the provider's package manifest file. For more information see Widget provider package manifest XML format. The message string can be simple text or the serialized form of an object interpreted by the web content. For more information, see PostWebMessageAsString.

C#

```
var message = $"{{ \"current_location\": \"{ location }\" }}";
WidgetManager.GetDefault().SendMessageToContent("Weather_Widget", message);
```

Limitations and requirements

- This feature is available only to users in the European Economic Area (EEA). In the EEA, installed apps that implement a feed provider can provide content feed in the Widgets Board.

Customize the widget header area

Article • 12/19/2024

In the latest release, apps that implement Windows widgets can customize the header that is displayed for their widget in the Widgets Board, overriding the default presentation. Header customization is implemented in the Adaptive Card payload you pass to the OS from your widget provider, so the steps are the same regardless of the language your widget provider is implemented in. For a walkthrough of creating a widget provider, see Implement a widget provider in a C# Windows App or Implement a widget provider in a win32 app (C++/WinRT).

The default header

By default, the widget header shows the display name and the icon specified in the app manifest file. The display name is specified with the **DisplayName** attribute of the **Definition** element and the icon is specified with an **Icon** element under **ThemeResources**. For more information about the widget app manifest file format, see Widget provider package manifest XML format.

The following example shows a portion of the Adaptive Card JSON payload for a widget that uses the default presentation. In the sections below, examples will be provided that modify this template to override the default header.

JSON

```
{
    "type": "AdaptiveCard",
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.6",
    "body": [
        ...
    ]
  }
```

Override the display name string

You can override the value specified in the **DisplayName** element in the app manifest by adding a `header` field to with the new display name in the JSON payload before sending it to the widget host.

The following example demonstrates overriding the display name string.

JSON

```
{
    "type": "AdaptiveCard",
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.6",
    "body": [
        ...
    ] ,
    "header": "Redmond Weather"
  }
```

Override the display name string and icon

To override both the display name string and the icon specified in the app manifest, add a `header` object with fields for `text` and `iconUrl`.

The following example demonstrates overriding the display name string and icon.

JSON

```
{
    "type": "AdaptiveCard",
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.6",
    "body": [
        ...
    ] ,
    "header": {
         "text": "Redmond weather",
         "iconUrl": "https://contoso.com/weatherimage.png"
      }
  }
```

Set the header to be empty

Some widget providers may want to allow their full UX to expand into the header region of the widget, even though this area of the widget isn't actionable. For this scenario, you can set the header to be empty by setting the `header` feel to `null`. Note that the UX in the header is not clickable by the user.

The following example demonstrates setting an empty header.

JSON

```
{
    "type": "AdaptiveCard",
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.6",
    "body": [
        ...
    ] ,
    "header": null
}
```

Widget provider package manifest XML format

Article • 12/19/2024

In order to be displayed in the widgets host, apps that support Windows widgets must register their widget provider with the system. For Win32 apps, only packaged apps are currently supported and widget providers specify their registration information in the app package manifest file. This article documents the XML format for widget registration. See the Example section for a code listing of an example package manifest for a Win32 widget provider.

App extension

The app package manifest file supports many different extensions and features for Windows apps. The app package manifest format is defined by a set of schemas that are documented in the Package manifest schema reference. Widget providers declare their registration information within the uap3:AppExtension. The **Name** attribute of the extension must be set to "com.microsoft.windows.widgets".

Widget providers should include the uap3:Properties as the child of **uap3:AppExtension**. The package manifest schema does not enforce the structure of the **uap3:Properties** element other than requiring well-formed XML. The rest of this article describes the XML format that the Widget host expects in order to successfully register a widget provider.

XML

```
<uap3:Extension Category="windows.appExtension">
  <uap3:AppExtension Name="com.microsoft.windows.widgets"
DisplayName="WidgetTestApp" Id="ContosoWidgetApp" PublicFolder="Public">
    <uap3:Properties>
    <!-- Widget provider registration content goes here -->
    </uap3:Properties>
  </uap3:AppExtension>
</uap3:Extension>
```

WidgetProvider

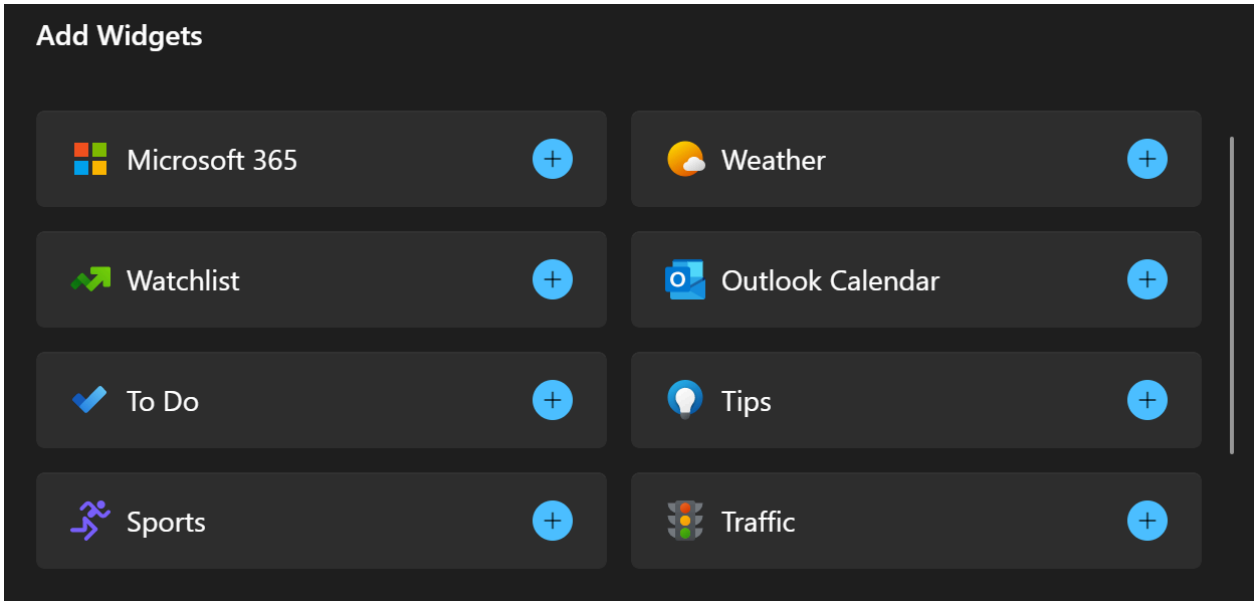
The root element of the widget provider registration information.



WidgetProviderIcons

Specifies icons representing the widget provider app.

Activation

Specifies activation information for the widget provider. If both **CreateInstance** and **ActivateApplication** are specified in the manifest, **CreateInstance** takes precedence.

CreateInstance

CreateInstance should be specified for Win32-based widget providers that implement the **IWidgetProvider** interface. The system will activate the interface with a call to CoCreateInstance. The **ClassId** attribute specifies the CLSID for the CreateInstance server that implements the **IWidgetProvider** interface.

Expand table

Attribute	Type	Required	Description	Default value
ClassId	GUID	Yes	The CLSID for the CreateInstance server that implements the widget provider.	N/A

ActivateApplication

When **ActivateApplication** is specified, the widget provider is activated via the command line, with the arguments provided as base64url encoded JSON strings. It is recommended that widget providers use the **CreateInstance** activation type. For information on the **ActivateApplication** command line format, see Widget provider ActivateApplication protocol.

Definitions

The container element for one or more widget registrations.

Definition

Represents the registration for a single widget.

Expand table

Attribute	Type	Required	Description	Default value
Id	string	Yes	An ID that identifies the widget. This value is also displayed in the navigation bar of the widget picker. Widget provider implementations use this string to determine or specify which of the app's widgets is being referenced for each operation. This string must be unique for all widgets defined within the app manifest file.	N/A
DisplayName	string	Yes	The name of the widget that is displayed on the widgets host.	N/A
Description	string	Yes	Short description of the widget.	N/A
AllowMultiple	boolean	No	Set to false if only one instance of this widget is supported. This attribute is optional and the default value is true.	true
IsCustomizable	boolean	No	Introduced in Windows App SDK 1.4. Set to true if your app supports widget customization. This causes the **Customize widget** button to be displayed in the widget's ellipsis menu.	false
AdditionalInfoUri	string	No	A URI that can be associated with the widget to be used when the user clicks on the title bar of	N/A

Attribute	Type	Required	Description	Default value
			the widget frame or when clicking the **Powered by** element of its context menu.	
ExcludedRegions	string	No	A list of regions where the widget should not be available. Widgets can specify **ExcludedRegions** or **ExclusiveRegions** but must not specify both in a single widget definition. The value of the attribute is a comma separated list of two character region codes.	N/A
ExclusiveRegions	string	No	A list of the only regions where the widget should be available. Widgets can specify **ExcludedRegions** or **ExclusiveRegions** but must not specify both in single widget definition. The value of the attribute is a comma separated list of two character region codes.	N/A
WebRequestFilter	string	No	Specifies the filter that specifies the resource request URLs for which the request will be intercepted and redirected to the widget provider's implementation of IWidgetResourceProvider.OnResourceRequested. The filter pattern is expressed using the format described in Match Patterns. The filter string in the registration must use Punycode where necessary. The filter string must match the origin of the widget registration, which is specified in the *webUrl* field of the adaptive card content.	N/A

Capabilities

Optional. Specifies capabilities for a single widget. If no capabilities are declared, one capability specifying a "large" size is added by default.

Capability

Specifies a capability for a widget.

Size

Specifies supported sizes for the associated widget.

Expand table

Attribute	Type	Required	Description	Default value
Name	string	Yes	Specifies a supported size for a widget. The value must be one of the following: "small", "medium", "large"	N/A

ThemeResources

Specifies theme resources for a widget.

Icons

A container element for one or more **Icon** elements.

Icon

Required. Specifies an icon that is displayed in the attribution area of the widget.

Expand table

Attribute	Type	Required	Description	Default value
Path	string	Yes	The package-relative path to an icon image file.	N/A

Screenshots

Required. Specifies one or more screenshots of the widget.

Screenshot

Required. Specifies a screenshot for a widget. This screenshot is shown in the widgets host in the **Add Widgets dialog** when the user is selecting widgets to add to the widgets host. If you provide a screenshot for the optional **DarkMode** or **LightMode** elements listed below, then the widgets host will use the screenshot that matches the current device theme. If you don't provide a screenshot for the current device theme, the image provided in this **Screenshot** element will be used. For information about the

design requirements for screenshot images and the naming conventions for localized screenshots, see Integrate with the widget picker.

> **Note**
>
> The widget screenshots are not displayed on the widgets board's add widgets dialog in the current preview release..

Expand table

Attribute	Type	Required	Description	Default value
Path	string	Yes	The package-relative path to a screenshot image file.	N/A
DisplayAltText	string	No	The alt-text for the image, for accessibility.	N/A

DarkMode

Optional. Specifies theme resources for when dark mode is active on the device. If you specify one or more screenshot images in the optional **DarkMode** element, the widgets host will select these screenshots when the device is in dark mode. If you don't provide a dark mode image, the widgets host will use the required, top-level **Screenshot** element described above. For information about the design requirements for screenshot images and the naming conventions for localized screenshots, see Integrate with the widget picker.

LightMode

Optional. Specifies theme resources for when light mode is active on the device. If you provide one or more screenshot images in the optional **LightMode** element, the widgets host will select these screenshots when the device is in light mode. If you don't provide a light mode image, the widgets host will use the required, top-level **Screenshot** element described above. For information about the design requirements for screenshot images and the naming conventions for localized screenshots, see Integrate with the widget picker.

Example

The following code example illustrates the usage of the widget package manifest XML format.

XML

```
<uap3:Extension Category="windows.appExtension">
  <uap3:AppExtension Name="com.microsoft.windows.widgets"
DisplayName="Widget Test App" Id="ContosoWidgetApp" PublicFolder="Public">
    <uap3:Properties>
      <WidgetProvider>
        <ProviderIcons>
            <Icon Path="Images\StoreIcon.png" />
        </ProviderIcons>
        <Activation>
          <!-- App exports COM interface which implements IWidgetProvider --
>
          <CreateInstance ClassId="XXXXXXXX-XXXX-XXXX-XXXX-D3397A3FF15C" />
        </Activation>
        <Definitions>
          <Definition
            Id="Weather_Widget"
            DisplayName="Microsoft Weather Widget"
            Description="Weather Widget Description"
            AdditionalInfoUri="https://contoso.com/widgets/Weather"
            ExclusiveRegions="US,UK"
            AllowMultiple="true">
            <Capabilities>
              <Capability>
                 <Size Name="small" />
              </Capability>
              <Capability>
                 <Size Name="medium" />
              </Capability>
              <Capability>
                 <Size Name="large" />
              </Capability>
            </Capabilities>

            <ThemeResources>
              <Icons>

```
                    <Screenshot Path="Assets\darkBackground.png"
DisplayAltText ="For accessibility"/>
                  </Screenshots>
                </DarkMode>

                <LightMode>
                  <Icons>
                    <Icon Path="Assets\light.png" />
                  </Icons>
                  <Screenshots>
                    <Screenshot Path="Assets\lightBackground.png"/>
                  </Screenshots>
                </LightMode>
              </ThemeResources>
            </Definition>
          </Definitions>
        </WidgetProvider>
      </uap3:Properties>
    </uap3:AppExtension>
</uap3:Extension>
```

Widget provider ActivateApplication protocol

Article • 03/09/2023

This article describes the format of the command line activation parameters for widgets providers that use the **ActivateApplication** activation type.

> **ⓘ Important**
>
> Widget providers specify an activation method in the Widget provider manifest file as described in the Widget provider package manifest XML format. It is recommended that widget providers use the **CreateInstance** activation type and respond to widget host requests using the **IWidgetProvider** interface methods instead of using the **ActivateApplication** activation method. The information in this article is provided for completeness and is not recommended for use by most widget provider implementations.

Arguments string in ActivateApplication and base64url encoding

When the widget provider is activated the command line will have `--widget-call=` prefixed before the base64url encoding in the command line arguments.

`--widget-call=[base64url]`

For example, the base64url part in

`--widget-call=ew0KICAgICJXaWRnZXRDYWxsIjoiQ3JlYXRlV2lkZ2V0IiwNCiAgICAiV2lkZ2V0Q29udGV4dCI6ew0KICAgICAgICAiSWQiOiI5ODU4MjEwOS1jNmJmLTQzNzItODlkNi04OWY1N2ViNzU0ZjYiLA0KICAgICAgICAiRGVmaW5pdGlvbk5hbWUiOiJQV0FfQ291bnRpbmdfV2lkZ2V0IiwNCiAgICAgICAgIlNpemUiOiJMYXJnZSINCiAgICB9DQp9`

is decoded into

JSON

```
{
    "WidgetCall":"CreateWidget",
    "WidgetContext":{
```

```
        "Id":"98582109-c6bf-4372-89d6-89f57eb754f6",
        "DefinitionId":"PWA_Counting_Widget",
        "Size":"Large"
    }
}
```

Command line format details

The Json command line encodes calls to the `IWidgetProvider` methods:

```c++
    interface IWidgetProvider
    {
        void CreateWidget(WidgetContext widgetContext);
        void DeleteWidget(String widgetId);
        void OnActionInvoked(WidgetCallInvokedArgs actionInvokedArgs);
        void OnWidgetContextChanged(WidgetContextChangedArgs
contextChangedArgs);
    }
```

Each activation represents one method call. The Json object has a `WidgetCall` value with the method name, and then a value for each parameter, named as the parameter name except capitalized. Each parameter is mapped as a pair<variable name, value> to the json object. For example, for the `WidgetContext widgetContext` parameter of the `CreateWidget` method, the `WidgetContext` is defined like this:

```c++
    runtimeclass WidgetContext
    {
        String Id { get; };
        String DefinitionId{ get; };
        String Size { get; };
    };
```

> ⓘ **Note**
>
> Widget providers should ignore unexpected parameter values to handle the case where additional parameters are added in the future.

The widget provider `CreateWidget` API call is marshalled to Json object:

```JSON
```

```
{
    "WidgetCall":"CreateWidget",
    "WidgetContext":{
        "Id":"98582109-c6bf-4372-89d6-89f57eb754f6",
        "DefinitionId":"PWA_Counting_Widget",
        "Size":"Large"
    }
}
```

The object will always include the `WidgetCall` value and all parameter values as specified by the `IWidgetProvider` method.

Marshalled objects examples

Create Widget Json object

JSON

```
{
    "WidgetCall":"CreateWidget",
    "WidgetContext":{
        "Id":"98582109-c6bf-4372-89d6-89f57eb754f6",
        "DefinitionId":"PWA_Counting_Widget",
        "Size":"Large"
    }
}
```

Delete Widget Json object

JSON

```
{
  "WidgetId": "1AC74363-177B-4CD2-995F-3B25AEEA3FF4",
  "WidgetCall": "DeleteWidget",
  "CustomState": "usedata"
}
```

OnActionInvoked Json Object

JSON

```
{
    "WidgetCall": "OnActionInvoked",
    "Args":{
```

```
        "Verb": "Verb String",
        "Data": "Data Details",
        "CustomState": "usedata",
        "WidgetContext": {
            "Id":"98582109-c6bf-4372-89d6-89f57eb754f6",
            "DefinitionId":"PWA_Counting_Widget",
            "Size":"Large"
        }
    }
}
```

Activate Json Object

JSON

```
{
    "WidgetCall": "Activate",
    "WidgetContext": {
        "Id":"98582109-c6bf-4372-89d6-89f57eb754f6",
        "DefinitionId":"PWA_Counting_Widget",
        "Size":"Large"
    }
}
```

Deactivate Json Object

JSON

```
{
    "WidgetCall": "Deactivate",
    "WidgetId":"98582109-c6bf-4372-89d6-89f57eb754f6"
}
```

OnWidgetContextChanged Json Object

For example WidgetSize is changed to Medium. In SV2, WidgetSize is the only thing which trig the WidgetContextChanged.

JSON

```
{
  "WidgetCall": "OnWidgetContextChanged",
  "Args":{
    "WidgetContext":{
            "Id":"98582109-c6bf-4372-89d6-89f57eb754f6",
            "DefinitionId":"PWA_Counting_Widget",
```

```
            "Size":"Medium"
        }
    }
}
```

Windows Copilot Runtime Actions providers

Article • 03/31/2025

Actions are atomic units of functionality that can be invoked by the Windows Copilot Runtime. Developers can register actions with the system by implementing an action provider app.

Responsible AI Notes

When building AI backed actions, it is your responsibility as the Action author to perform content moderation and abuse monitoring when it comes to entities returned to the user. For more information about Microsoft Responsible AI policies for more information, see Microsoft Responsible AI: Principles and approach

> **Note**
>
> Consider if children should have access to the action using the 'contentAgeRating' property in the action definition JSON.

Action definition JSON schema for Windows Copilot Runtime Action providers

Article • 03/28/2025

This article describes the format of the action definition JSON file format for Windows Copilot Runtime Actions. This file must be included in your project with the **Build Action** set to "Content" and **Copy to Output Directory** set to “Copy if newer”. Specify the package-relative path to the JSON file in your package manifest XML file. For more information, see Action provider package manifest XML format.

Example action definition JSON file

JSON

```
"version": 1,
  "actions": [
    {
      "id": "Contoso.SampleGreeting",
      "description": "Send greeting with Contoso",
      "icon": "ms-resource//...",
      "inputs": [
        {
          "name": "UserFriendlyName",
          "kind": "Text"
        },
        {
          "name": "PetName",
          "kind": "Text",
          "required": false
        }
      ],
      "inputCombinations": [
        {
          "inputs": ["UserFriendlyName"],
          "description": "Greet ${UserFriendlyName.Text}"
        },
        {
          "inputs": ["UserFriendlyName", "PetName"],
          "description": "Greet ${UserFriendlyName.Text} and their pet
${PetName.Text}"
        }
      ],
      "contentAgeRating": "child",
      "invocation":
      {
```

```
        {
          "type": "Uri",
          "uri": "contoso://greetUser?
userName=${UserFriendlyName.Text}&petName=${PetName.Text}",
        },
        "where": [
          "${UserFriendlyName.Length > 3}"
        ]
      }
    },
    {
      "id": "Contoso.SampleGetText",
      "description": "Summarize file with Contoso",
      "icon": "ms-resource://...",
      "inputs": [
        {
          "name": "FileToSummarize",
          "kind": "File"
        }
      ],
      "inputCombinations": [
        {

  ]
}
```

Action definition JSON properties

The tables below describe the properties of the action definition JSON file.

Document root

Expand table

Property	Type	Description	Required
version	string	Schema version. When new functionality added, the version increments by one.	Yes.
actions	Action[]	Defines the actions provided by the app.	Yes.

Action

Expand table

Property	Type	Description	Required
id	string	Action identifier. Must be unique per app package. This value is not localizable.	Yes
description	string	User-facing description for this action. This value is localizable.	Yes
icon	string	Localizable icon for the action. This value is an *ms-resource* string for an icon deployed with the app.	No
inputs	Inputs[]	List of entities that this action accepts as input.	Yes
inputCombinations	InputCombination[]	Provides descriptions for different combinations of inputs.	Yes
outputs	Output[]	If specified, must be an empty string in the current release.	No
invocation	Invocation	Provides information about how the action is invoked.	Yes
contentAgeRating	string	A field name from the UserAgeConsentGroup that specifies the appropriate age rating for the action. The allowed values are "Child", "Minor", "Adult". If no value is specified, the default behavior allows access to all ages.	No

Output

Expand table

Property	Type	Description	Required
name	string	The variable name of the entity. This value is not localizable.	Yes
kind	string	A field name from the **ActionEntityKind** enumeration specifying the entity type. This value is not localizable. The allowed values are "None", "Document", "File", "Photo", "Text".	Yes

InputCombination

Expand table

Property	Type	Description	Required
inputs	string[]	A list of Input names for an action invocation. The list may be empty.	Yes
description	string	Description for the action invocation. This value is localizable.	No
where	string[]	One or more conditional statements determining the conditions under which the action applies.	No

Invocation

Expand table

Property	Type	Description	Required
type	string	The instantiation type for the action. The allowed values are "uri" and "com"	Yes
uri	string	The absolute URI for launching the action. Entity usage can be included within the string.	Yes, for URI instantiated actions.
clsid	string	The class ID for the COM class that implements **IActionProvider**.	Yes, for COM actions
inputData	A list of name/value pairs specifying additional data for URI actions.	No. Only valid for URI actions.	

ActionEntityKind enumeration

The **ActionEntityKind** enumeration specifies the types of entities that are supported by the Windows Copilot Runtime Actions. In the context of a JSON action definition, the entity kinds are string literals that are case-sensitive.

Expand table

Entity kind string	Description
"File"	Includes all file types that are not supported by photo or document entity types.
"Photo"	Image file types. Supported image file extensions are ".jpg", ".jpeg", and ".png"
"Document"	Document file types. Supported document file extensions are ".doc", ".docx", ".pdf", ".txt"
"Text"	Supports strings of text

Entity properties

Each entity type supports one or more properties that provide instance data for the entity. Entity property names are case sensitive.

The following example illustrates how entities are referenced in the query string for actions that are launched via URI activation:

```
...?param1=${entityName.property1}&param2=${entityName.property2}
```

For information on using entity properties to create conditional sections in the action definition JSON, see Where clauses.

File entity properties

Expand table

Property	Type	Description
"FileName"	string	The name of the file.
"Path"	string	The path of the file.
"Extension"	string	The extension of the file.

Document entity properties

The *Document* entity supports the same properties as *File*.

Photo entity properties

The *Photo* entity supports all of the properties of *File* in addition to the following properties.

Expand table

Property	Type	Description
"IsTemporaryPath"	boolean	A value specifying whether the photo is stored in a temporary path. For example, this property is true for photos that are stored in memory from a bitmap, not stored permanently in a file.

Text entity properties

Expand table

Property	Type	Description
"Text"	string	The full text.
"ShortText"	string	A shortened version of the text, suitable for UI display.
"Title"	string	The title of the text.
"Description"	string	A description of the text.
"Length"	double	The length of the text in characters.
"WordCount"	double	The number of words in the text.

Where clauses

The action definition JSON format supports *where* clauses that can be used to implement conditional logic, such as specifying that an action should be invoked only when an entity property has a specified value.

The following operators can be used with *where* clauses.

Expand table

Operator	Description
==	Equality
~=	Case-insensitive equality
!=	Inequality
<	Less than
<=	Less than or equal to
>	Greater than
>=	Greater than or equal to
||	Logical OR
&&	Logical AND

Where clauses use the following format:

JSON

```
"where": [
    "${<property_accessor>} <operator> <value>"
]
```

The following example shows a *where* clause that evaluates to true if a **File** entity has the file extension ".txt".

JSON

```
"where": [
    "${File.Extension} ~= \".txt\""
]
```

Multiple *where* clauses can be combined using the logical AND and logical OR operators.

JSON

```
"where": [
  "${File.Extension} ~= \".txt\" || ${File.Extension} ~= \".md\""
]
```

Windows Copilot Runtime Action provider package manifest XML format

Article • 03/31/2025

This article describes the package manifest XML format for Windows Copilot Runtime Actions.

App extension

The app package manifest file supports many different extensions and features for Windows apps. The app package manifest format is defined by a set of schemas that are documented in the Package manifest schema reference. Action providers declare their registration information within the uap3:AppExtension. The **Name** attribute of the extension must be set to "com.microsoft.windows.ai.actions".

Action providers should include the uap3:Properties as the child of **uap3:AppExtension**. The package manifest schema does not enforce the structure of the **uap3:Properties** element other than requiring well-formed XML.

Action providers must provide a **Registration** element which specifies the path to the action definition JSON file. For more information, see Action JSON schema for Windows Copilot Action providers.

XML

```
<uap3:Extension Category="windows.appExtension">
    <uap3:AppExtension
        Name="com.microsoft.windows.ai.actions"
        DisplayName="..."
        Id="..."
        PublicFolder="Assets">
      <uap3:Properties>
        <Registration>path\to\registration.json</Registration> <!-- path
relative to the PublicFolder above -->
      </uap3:Properties>
    </uap3:AppExtension>
</uap3:Extension>
```

Additional requirements

Both COM and URI-launched action providers must have package identity. Package identity is declared in the app package manifest file using the Identity element. For more information, see An overview of Package Identity in Windows apps.

COM-based action providers must be *full trust apps* which have an integrity level of *mediumIL*. This is declared in the app package manifest file by setting the *uap10:TrustLevel attribute to "mediumIL".

URI-launched action providers must also have a trust level of *mediumIL*. If a URI-launched action provider will return outputs, the app must implement the ability to be launched for results. For more information, see Launch an app for results. URI-launched action providers that return outputs must also instantiate the runtime.

DispatcherQueue

Article • 08/31/2023

Highlights

- The DispatcherQueue class in the Windows App SDK manages a prioritized queue on which the tasks for a thread execute in a serial fashion.
- It provides a means for background threads to run code on a **DispatcherQueue**'s thread (for example, the UI thread where objects with thread-affinity live).
- The class precisely integrates with arbitrary message loops. For example, it supports the common Win32 idiom of nested message loops.
- The AppWindow class integrates with **DispatcherQueue**—when a **DispatcherQueue** for a given thread is being shut down, the **AppWindow** instances are automatically destroyed.
- It provides a means to register a delegate that's called when a timeout expires.
- It provides events that let components know when a message loop is exiting, and optionally defer that shutdown until outstanding work completes. That ensures components that use the **DispatcherQueue**, but don't own the message loop, may do cleanup on-thread as the loop exits.
- The **DispatcherQueue** is a thread singleton (there can be at most one of them running on any given thread). By default, a thread has no **DispatcherQueue**.
- A thread owner may create a DispatcherQueueController to initialize the **DispatcherQueue** for the thread. At that point, any code can access the thread's **DispatcherQueue**; but only the **DispatcherQueueController**'s owner has access to the DispatcherQueueController.ShutdownQueue method, which drains the **DispatcherQueue**, and raises **ShutdownStarted** and **ShutdownCompleted** events.
- An outermost message loop owner must create a **DispatcherQueue** instance. Only the code in charge of running a thread's outermost message loop knows when dispatch is complete, which is the appropriate time to shut down the **DispatcherQueue**. That means that components that rely on **DispatcherQueue** mustn't create the **DispatcherQueue** unless they own the thread's message loop.

Run-down

After a thread exits its event loop, it must shut down its **DispatcherQueue**. Doing so raises the **ShutdownStarting** and **ShutdownCompleted** events, and drains any final pending enqueued items before disabling further enqueuing.

- To shut down a **DispatcherQueue** that's running on a dedicated thread with a **DispatcherQueue**-owned message loop, call the DispatcherQueueController.ShutdownQueueAsync method.
- For scenarios where the app owns an arbitrary message loop (for example, XAML Islands), call the synchronous DispatcherQueueController.ShutdownQueue method. That method raises shutdown events, and drains the **DispatcherQueue** synchronously on the calling thread.

When you call either **DispatcherQueueController.ShutdownQueueAsync** or **DispatcherQueueController.ShutdownQueue**, the order of events raised is the following:

- **ShutdownStarting**. Intended for apps to handle.
- **FrameworkShutdownStarting**. Intended for frameworks to handle.
- **FrameworkShutdownCompleted**. Intended for frameworks to handle.
- **ShutdownCompleted**. Intended for apps to handle.

The events are separated into application/framework categories so that orderly shutdown can be achieved. That is, by explicitly raising application shutdown ahead of framework shutdown events, there's no danger that a framework component will be in an unusable state as the application winds down.

C++/WinRT

```
namespace winrt
{
    using namespace Microsoft::UI::Dispatching;
}

// App runs its own custom message loop.
void RunCustomMessageLoop()
{
    // Create a DispatcherQueue.
    auto
dispatcherQueueController{winrt::DispatcherQueueController::CreateOnCurrentT
hread()};

    // Run a custom message loop. Runs until the message loop owner decides
to stop.
    MSG msg;
    while (GetMessage(&msg, nullptr, 0, 0))
    {
        if (!ContentPreTranslateMessage(&msg))
        {
            TranslateMesasge(&msg);
            DispatchMessage(&msg);
        }
    }
```

```
    // Run down the DispatcherQueue. This single call also runs down the
system DispatcherQueue
    // if one was created via EnsureSystemDispatcherQueue:
    // 1. Raises DispatcherQueue.ShutdownStarting event.
    // 2. Drains remaining items in the DispatcherQueue, waits for
deferrals.
    // 3. Raises DispatcherQueue.FrameworkShutdownStarting event.
    // 4. Drains remaining items in the DispatcherQueue, waits for
deferrals.
    // 5. Disables further enqueuing.
    // 6. Raises the DispatcherQueue.FrameworkShutdownCompleted event.
    // 7. Raises the DispatcherQueue.ShutdownCompleted event.

    dispatcherQueueController.ShutdownQueue();
}
```

Outermost and recursive message loops

DispatcherQueue supports custom message loops. However, for simple apps that don't need customization, we provide a default implementations. That removes a burden from developers, and helps ensure consistently correct behavior.

C++/WinRT

```
namespace winrt
{
    using namespace Microsoft::UI::Dispatching;
}

// Simple app; doesn't need a custom message loop.
void RunMessageLoop()
{
    // Create a DispatcherQueue.
    auto
dispatcherQueueController{winrt::DispatcherQueueController::CreateOnCurrentT
hread()};

    // Runs a message loop until a call to
DispatcherQueue.EnqueueEventLoopExit or PostQuitMessage.
    dispatcherQueueController.DispatcherQueue().RunEventLoop();

    // Run down the DispatcherQueue.
    dispatcherQueueController.ShutdownQueue();
}

// May be called while receiving a message.
void RunNestedLoop(winrt::DispatcherQueue dispatcherQueue)
{
    // Runs a message loop until a call to
DispatcherQueue.EnqueueEventLoopExit or PostQuitMessage.
    dispatcherQueue.RunEventLoop();
```

```
}

// Called to break out of the message loop, returning from the RunEventLoop
call lower down the
// stack.
void EndMessageLoop(winrt::DispatcherQueue dispatcherQueue)
{
    // Alternatively, calling Win32's PostQuitMessage has the same effect.
    dispatcherQueue.EnqueueEventLoopExit();
}
```

System dispatcher management

Some Windows App SDK components (for example, MicaController) depend on system components that in turn require a system **DispatcherQueue** (**Windows.System.DispatcherQueue**) running on the thread.

In those cases, the component that has a system **DispatcherQueue** dependency calls the EnsureSystemDispatcherQueue method, freeing your app from managing a system **DispatcherQueue**.

With that method called, the Windows App SDK **DispatcherQueue** manages the lifetime of the system **DispatcherQueue** automatically, shutting down the system **DispatcherQueue** alongside the Windows App SDK **DispatcherQueue**. Components might rely on both Windows App SDK and system **DispatcherQueue** shutdown events in order to ensure that they do proper cleanup after the message loop exits.

C++/WinRT

```
namespace winrt
{
    using namespace Microsoft::UI::Composition::SystemBackdrops;
    using namespace Microsoft::UI::Dispatching;
}

// The Windows App SDK component calls this during its startup.
void MicaControllerInitialize(winrt::DispatcherQueue dispatcherQueue)
{
    dispatcherQueue.EnsureSystemDispatcherQueue();

    // If the component needs the system DispatcherQueue explicitly, it can
now grab it off the thread.
    winrt::Windows::System::DispatcherQueue systemDispatcherQueue =
        winrt::Windows::System::DispatcherQueue::GetForCurrentThread();
}

void AppInitialize()
{
```

```
    // App doesn't need to concern itself with the system DispatcherQueue
dependency.
    auto micaController = winrt::MicaController();
}
```

AppWindow integration

The AppWindow class has functionality that integrates it with the **DispatcherQueue**, so that **AppWindow** objects can automatically be destroyed when the DispatcherQueueController.ShutdownQueueAsync or DispatcherQueueController.ShutdownQueue method is called.

There's also a property of **AppWindow** that allows callers to retrieve the **DispatcherQueue** associated with the **AppWindow**; aligning it with other objects in the **Composition** and **Input** namespaces.

AppWindow needs your explicit opt-in in order to be aware of the **DispatcherQueue**.

C++/WinRT

```
namespace winrt
{
    using namespace Microsoft::UI::Dispatching;
    using namespace Microsoft::UI::Windowing;
}

void Main()
{
    // Create a Windows App SDK DispatcherQueue.
    auto
dispatcherQueueController{winrt::DispatcherQueueController::CreateOnCurrentT
hread()};

    var appWindow = AppWindow.Create(nullptr, 0,
dispatcherQueueController.DispatcherQueue());

    // Since we associated the DispatcherQueue above with the AppWindow,
we're able to retreive it
    // as a property. If we were to not associate a dispatcher, this
property would be null.
    ASSERT(appWindow.DispatcherQueue() ==
dispatcherQueueController.DispatcherQueue());

    // Runs a message loop until a call to
DispatcherQueue.EnqueueEventLoopExit or PostQuitMessage.
    dispatcherQueueController.DispatcherQueue().RunEventLoop();

    // Rundown the Windows App SDK DispatcherQueue. While this call is in
progress, the AppWindow.Destoyed
```

```
    // event will be raised since the AppWindow instance is associated with
the DispatcherQueue.
    dispatcherQueueController.ShutdownQueue();
}
```

Windows app performance and fundamentals overview

Article • 02/27/2025

Improving the performance and fundamentals of your application gives it a feeling of polish and craftsmanship, while saving your customers time, money, battery life, and development effort. Your app will consume less power, improving battery life and reducing carbon emissions. Apps run more smoothly on less expensive hardware. Your customers' productivity increases.

This page provides an overview of the technologies and development tools for measuring, understanding, and refining the performance of your Windows application. If you are writing a UWP application, be sure to also consult the UWP Performance documentation.

What is application performance and why is it important?

Performance in the context of an application usually revolves around *cost*. How long is it going to take to complete a particular task? How much of the system's resources will be used?

The answers to these questions play a fundamental role in the quality of a user's experience with an application (you can likely recall times where as a user, you have felt frustrated at an application for its poor performance!). As a developer, by keeping performance in mind, you will ensure that users of your applications don't experience that same frustration.

To learn more about the importance of performance and suggestions on how to get started, see this introduction to the world of performance.

What tools can I use to measure application performance?

There are a variety of different options available for measuring the performance of your Windows application.

If you are not sure what tools to choose, check out the article: Choosing between Visual Studio Performance Profiler and Windows Performance Toolkit.

Visual Studio Performance Profiler

Visual Studio offers tooling to help you monitor your application and give you insights within your source. Visit the resources below to learn about how you can use these tools to optimize your code right from your development environment.

- Measure app performance in Visual Studio
- Case Study: Using Visual Studio Profiler to reduce memory allocations in the Windows Terminal console host startup path
- Case Study: Double Performance in under 30 minutes

Windows Performance Toolkit

Windows Performance Recorder and Windows Performance Analyzer enable detailed monitoring and analysis of your application and the entire system using Event Tracing for Windows (ETW). See the links below on how to get started.

- Getting Started with the Windows Performance Toolkit
- Windows Performance Recorder Intro
- Windows Performance Analyzer Intro

PerfView

PerfView is an open source monitoring and analysis tool created by the .NET team for investigating .NET performance issues. Because of its ability to decode .NET symbols and managed memory, it is an ideal choice for managed applications.

- PerfView GitHub Repository
- PerfView Tutorial Series

SizeBench

SizeBench is a utility that helps you investigate and reduce the size of your compiled native code binaries (DLLs, EXEs, and other PE files).

- SizeBench: A new tool for analyzing Windows binary size .

- Performance problems in your compile-debug-test loop? Report them in the Windows Dev Performance repo on GitHub.

Performance and Sustainability

Performance engineering intersects directly with the sustainable software movement. Most electrical grids burn fossil fuels to generate electricity. As your application runs on a PC, it consumes incremental power that may be small for a single user but adds up as your user base grows.

Interested in learning how performance engineering intersects with sustainability? Check out the Principles of Green Software Engineering and Microsoft's Sustainable Software blog.

Our content road map

Performance can be a tricky part of your development process without the right guidance. Ensuring that the right documentation is available for app developers is key to creating faster apps. The road map below details the next pages to be added to this doc set, and in the order that they will be published. If you see something you like or

something that's missing, let us know on GitHub via the Feedback links at the bottom of this page! Our goal is to curate a well-rounded and educational doc set for app performance that meets your needs, so we'd love to hear from you. Please feel welcome to submit feedback for this page below with your recommendations for what you would like to see covered in regard to Windows application performance.

Expand table

Topic	Description
Introduction to performance areas	Descriptions of what performance means in the context of CPU, memory, GPU, etc.
Identifying what to measure	Depending on your workload, environment, and other factors, certain areas of performance may be more of a focus than others. Learn what to measure and when with this doc
Performance Testing Cycle	Step with us through the performance testing lifecycle which includes setting up your test environment, analyzing your results and making product improvements
Understanding the different performance tools	This doc will introduce more performance tooling and go over the use cases and best practices for using them

Introduction to Windows Application Performance

Article • 11/05/2021

Performance is an aspect of software development that focuses on measuring and improving code. After reading this article, you will have a better idea of: what performance entails, why it is important for you and your customers, and how to get started with measuring your application's performance.

What is application performance?

Performance is the measure of how effectively your application uses the system's resources to do what you've designed it to do. It covers different aspects of how your program interacts with the underlying device. This can include things like:

- CPU usage
- Memory consumption
- Power consumption
- Network and storage utilization
- Animation performance

...and more.

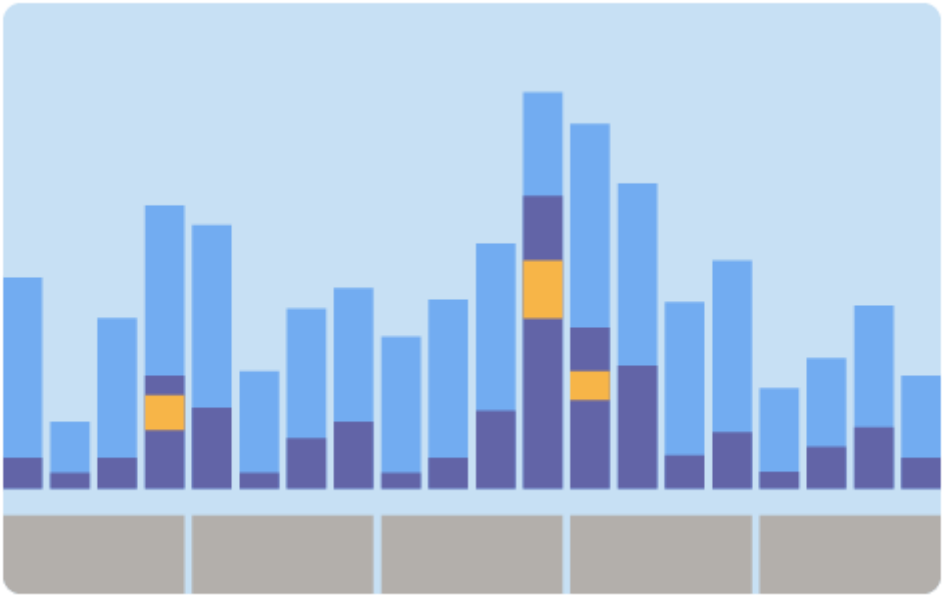
All of these different properties have an element of cost associated with them: for example, how much CPU does my application use? How much of the user's bandwidth

will it consume? How fast does this particular page of my application load? Measurement is therefore central to performance.

Why is it important?

Users expect performance as a fundamental property of the software they use. They want their applications to be responsive and make efficient use of their system's resources. Applications that exhibit poor performance cause frustration, which can lead to reduced user engagement. To provide your customers with the best possible experience, it is therefore crucial to make performance a regular part of your development workflow.

When should you measure application performance?



Application performance can span many stages of the development process. It has implications on everything ranging from your choice of data structure to the technology that you choose for building your application.

Keep performance in mind as you are developing your application, and plan to do regular performance testing as part of updating and maintaining your application.

How is application performance measured?

Here are some suggestions for how to approach testing your application for performance.

- **Leverage your knowledge of your application.** Understanding the most common scenarios for your users will enable you to spend your time wisely on optimizing the right things. Unclear scenarios can make your measurements difficult to interpret, so don't skip this step! If you have data available on how users interact with your application, this would be a great time to look at it.
  - Where are your users spending most of their time?
  - What are the most important things that a customer will do with your software?
  - What are your application's hardware requirements?
- **Set performance goals for your most important user scenarios.**
- **Be precise about what you are trying to optimize.** Is it CPU? Battery? Network throughput?
- **Select the tools you will use to do your measurements.**
- **Apply a scientific mindset when testing.** Create benchmarks in a controlled environment. Then, make your change, and re-measure to see how your changes have affected your application's behavior.
- **Add regression testing into your test environment.** This will ensure that your performance metrics don't regress over time. Modern hardware is complex and measuring the impact of your performance improvements can be a challenge. Investigating, measuring, and testing your application performance in these ways will ensure you know the impact of your work.

Intertwining metrics

While you will typically focus on one area of performance during your analysis, be aware that areas are often intertwined. An improvement in one can cascade into an improvement in the other areas.

For example, fixing power consumption is frequently a synchronization problem. Reducing memory usage can result in reducing the time spent using the CPU.

There can also be situations where additional resources spent in one area yield a more impactful improvement in another area.

For example, increasing memory consumption can decrease network or storage utilization through caching.

The decision to make a change depends on what is most important for your customers. It is also part of the challenge (and fun!) of performance work.

Next steps

With this background in place, here are some actions you can now take:

- **Identify your application's most common scenarios**. These will be the basis of what you are trying to measure.
- **Figure out your test strategy.** What will be your test environment and choice of measurement tools?

Head to the Windows app performance overview to learn more about the tools and guidance that are available for you to use on your performance journey.

Choosing among Visual Studio Performance Profiler, Windows Performance Toolkit, and PerfView

Article • 03/03/2025

This guide provides a general comparison of the primary general-purpose performance profiling technologies at Microsoft: Visual Studio Performance Profiler, Windows Performance Toolkit, and PerfView.

These tools can help you to diagnose and understand the performance characteristics of your applications on Windows. The goal of this guide is to provide an overview of when to use one over another, highlighting each of their strengths, and offering a brief overview of the functionality they contain.

Overview

Visual Studio Performance Profiler is created by the Visual Studio team for quickly understanding performance characteristics of an application under development inside the existing Visual Studio project system. Its strength is integrating tightly with the active development project, simplifying analysis of the most common performance scenarios, and quick, easy collection of only a single application.

Windows Performance Toolkit is created by the Windows team for understanding system wide characteristics of the entire PC at once. While it grew up from the need to analyze hardware and drivers, it is very effective on understanding software problems as well. Its strength is around gathering large quantities of information from the entire machine at once, so multi-process issues, those dealing with hardware or drivers, and complex scenarios are well-matched for these tools.

PerfView is created by the .NET team for understanding the performance of .NET applications. Like Windows Performance Toolkit, it can gather large quantities of information from the entire machine at once. It is differentiated by its ability to display very detailed information about .NET runtime services such as garbage collection, just-in-time compilation, and the managed thread pool. PerfView can be used for managed, native, and mixed-mode applications.

There is overlap between these tools. Often you can start exploring an issue in one tool and switch to another for a different view of the same scenario. Other times, one of the tools will be more effective than the others.

Installation

The Visual Studio Performance Profiler is a component of Visual Studio itself and is installable through the same installation wizard as the rest of the development environment.

The Windows Performance Toolkit is downloadable separately as a part of the Windows Assessment and Deployment Kit. However, the command-line Performance Recorder tool is pre-installed with Windows 10 and Windows 11 as `wpr.exe` available on the default path variable from shells like PowerShell and the Command Prompt.

The Performance Analyzer is available as an application in the Microsoft Store.

PerfView is available as a standalone download in the PerfView GitHub Releases page. No installation is required.

Customizing for advanced performance analysis scenarios

Windows Performance Toolkit additionally offers two extensibility points that can serve advanced performance analysis scenarios.

- The Microsoft Performance Toolkit SDK handles the processing of trace data and enables developers to build their own plugins to be viewed inside the Windows Performance Analyzer.
- .NET TraceProcessing allows the authoring of custom tools that can process trace information into resulting tables and is especially useful for automated analysis of bulk trace data.

PerfView is similarly based on the .NET TraceEvent library for programmatically consuming performance traces. TraceEvent can be used independently of PerfView to perform custom analysis of performance trace data.

> **Note**
>
> For performance analysis scenarios to work, you will need access to the **symbols** that correlate with the Windows application being tested. When building with Visual Studio, they will be located the same as in the **debugging scenario settings**, either built with your solution or captured from symbol servers. When analyzing other libraries or components, you will have to locate the symbols for those components to complete your analysis.

Considerations for choosing a tool

The tool to choose depends on the performance scenario that you are attempting to explore. A comparison of functionalities and traits among the tools is provided in the following table where:

- **Well supported** means the tool is designed for the intended task and achieves robust and detailed results.
- **Supported** means the tool may require additional configuration or steps to achieve the desired results. May contain a limited scope of action within the category.
- **Not supported** means the tool is not designed for this use.

> **Tip**
>
> For a general rule, start with *Visual Studio Profiling* when possible. Move on to *Windows Performance Toolkit* or *PerfView* when reaching the limits of what the Visual Studio tools can do.

Situation	Visual Studio Performance Profiler	Windows Performance Toolkit	PerfView
Custom Scenarios	Not supported	**Well supported**	**Well supported**

General use considerations

For those just getting started with performance analysis, we recommend Visual Studio Performance Profiler as a well-integrated feature inside the existing Visual Studio development suite. We recommend using Visual Studio Performance Profiler over PerfView if it meets your needs.

For more complex system performance analysis that may require more power and versatility, we recommend Windows Performance Toolkit, which consists of two tools used to accomplish performance analysis tasks:

- The **Windows Performance Recorder**, available both as a command-line tool and with a graphical interface, is responsible for capturing the trace session.
- The **Windows Performance Analyzer** is opened later to post-process the collected data and provide a highly customizable analysis view.

A few of the benefits that Visual Studio Performance Profiler offers include:

- A **good introduction** to performance analysis in the major domains.
- It **handles many of the complexities of analysis and debugging automatically** based on the project configuration.
- It **automatically highlights major areas of concern**.
- It is **better for focusing on just one application**, with a smaller, more focused data set and a smaller collection scope.
- More specific focus translates to **less impact on other applications** and machine hardware while profiling occurs, a **reduced overall size to the tracing files** generated and stored, and an **increased processing speed** for reviewing information after collection is complete.
- Takes **less time to start and complete a trace**, with a faster ability to review and turn around because Visual Studio Performance Profiler is concerned only with the application and not the entire system.
- Data collection and resulting analysis are **all performed within Visual Studio**, with analysis pages launching automatically on the conclusion of collection. The report view also automatically tends to focus attention on hot spots or areas of action.

A few of the benefits that Windows Performance Toolkit offers include:

- **Ample documentation and blogs** are provided by the Windows Performance and Diagnostics teams to help you get started.
- It is **better for collecting very large files**, especially from systems that are busy with background tasks. It is a catch-all tool for collecting information that will then be filtered later in the Windows Performance Analyzer interface.
- **Ability to be customized for advanced performance analysis scenarios** using extensibility points. (See below)

A few of the benefits that PerfView offers include:

- Comprehensive **built-in documentation and Internet-accessible how-to videos** linked from within the app.
- It is **easy to deploy** to production environments by simply copying PerfView.exe.
- A **flight-recorder mode** for capturing hard-to-reproduce issues.
- Very detailed diagnostics for .NET runtime services.
- Extensible for custom views.

Scope of work considerations

For analyses surrounding a **single application** and especially a **single process**, all of the tools are very capable for collecting and understanding performance. The advantage, however, would side with Visual Studio Performance Profiler, especially when the application source and project system is already available. The Visual Studio Performance Profiler engine is designed to collect CPU, GPU, and memory information from a binary in a similar streamlined fashion to the F5 debugging capability. While only focusing on the one application at hand, this collection mechanism offers a tighter turn around and developer loop.

Choose PerfView if Visual Studio doesn't have the necessary capabilities, can't be run due to collection requirements (common in production environments), or more detailed .NET diagnostic capabilities are needed.

For situations with **larger complexity** that include **multiple cross-process requests**, **hardware devices** and their **drivers**, or deep dives into **Windows platform technologies**, the Windows Performance Toolkit is the optimal choice.

Hardware considerations

Visual Studio Performance Profiler, Windows Performance Toolkit, and PerfView can diagnose CPU and memory for major hardware components, with Visual Studio

Performance Profiler and Windows Performance Toolkit additionally supporting GPU. The tools are generally well-matched at introductory analysis in these areas.

CPU usage can be analyzed with all three tools and is typically captured using sampling. The sampling captures stack traces from the application periodically and provides a ranking on how often they appear. Both tools can adjust this behavior to instead use instrumentation for exact accounting.

GPU usage can be analyzed with both Visual Studio Performance Profiler and Windows Performance Toolkit capturing a general overview of information.

Memory usage can be analyzed with all three tools collecting information on the heap space and the stacks associated with allocations in the heap.

When more complex scenarios arise, such as analyzing networking, disk, devices, handles, or overall power consumption of the system, Windows Performance Toolkit is more equipped to handle the analysis. This data is best collected directly from the operating system as it dispatches requests to the various hardware components. Windows Performance Toolkit is developed in tandem with the operating system, so it is ready and capable of collecting this more system-focused category of information.

Code language support considerations

Windows Performance Toolkit is primarily focused on support for C and C++, as these languages are used in the Windows operating system codebase.

Visual Studio Performance Profiler support is focused on a wider range of programming languages, starting with .NET originating technologies like C# and ASP.NET then expanding outward.

PerfView supports .NET and native (C and C++) applications. It has deep knowledge of .NET runtimes, and capabilities around ASP.NET web workloads.

This is not to say that Visual Studio cannot analyze C or C++ code, or that Windows Performance Analyzer cannot analyze .NET applications, or that PerfView cannot analyze web applications. It is just best to start with the tool most closely matching the application being analyzed to take advantage of each tool's strengths.

Scenario considerations

All of the tools contain several scenario-based options for studying application performance.

Visual Studio Performance Profiler options tend to focus on .NET, user interface (UI), and databases residing within the application being analyzed.

Windows Performance Toolkit tends to focus on operating system components and frameworks like composition, browser views, and glitches in realtime processing pipelines.

For scenarios that require a more customized solution, Windows Performance Recorder can combine both system-wide collection and application-related collection data into a single recording session. This functionality enables an application developer to offer a complete solution to deploy to customers for requesting performance data from hardware that might differ from that used to develop the product. More information on this mechanism can be found at the Authoring Custom Profiles blog series by the Windows Performance and Diagnostics team.

PerfView is targeted at deep investigations of .NET applications and runtimes, but is just as capable in multi-process and operating system-level investigations.

Summary

Visual Studio Performance Profiler, Windows Performance Toolkit, and PerfView are three robust tools from Microsoft available to you for understanding your application's performance. Choosing which tool will best meet your needs requires a variety of considerations regarding your specific situation. We hope that this guide will provide the information needed for you to make wise performance analysis choices, but also welcome you to file feedback on this page below, or for issues specifically pertaining to Windows development performance, please file an issue on the Windows Dev Performance repo.

Improve app performance by reducing the use of memory and disk space

Article • 05/17/2022

This guide will demonstrate how to improve the performance of your Windows application in two primary ways:

- Minimize memory usage
- Efficiently use Disk Space

Minimize memory usage

There are a variety of ways to minimize the amount of memory that your Windows app uses, you can:

- Reduce foreground memory usage
- Minimize background work
- Release resources while in the background
- Ensure your application does not leak memory

In order to appropriately minimize memory usage, it is first important to understand:

- how memory is used and allocated, using the working set, dynamic memory, and virtual allocation,
- how to capture a system trace, and
- how to analyze the system trace.

Once you have a system trace to analyze, we will recommend guidance for Applying your trace analysis to reduce memory usage.

Working set, dynamic memory, and virtual allocation

The working set of an application – the set of pages in its virtual address space that currently resident in memory – is one measure of the app's memory usage.

The amount of memory that an application uses impacts its runtime performance, as well as the responsiveness of the system as a whole. Minimizing the use of memory will help the app to perform better by reducing the CPU costs associated with accessing more memory. Lower memory usage also helps with the system responsiveness, and the

app user's experience in general, as the application does not end up displacing other memory content.

Memory displacement can happen as the system attempts to retain in-memory content accessed recently and, if necessary, will trim and page-out content used earlier. When the user switches back to the shell, or another application, and the necessary data is not resident in-memory, the data will need to be read from the disk. The user will likely notice a slowdown due to this process.

There are two key pieces to the memory used by an application: 1) dynamic memory, and 2) file-backed memory. File-backed memory usage comes from binaries and data files, such as databases, used by an application. This is commonly not a significant chunk of an application's memory usage and often a constant. *(Exceptions would be data processing applications, code compilation etc.)* The more significant source of memory usage and where leaks manifest is dynamic memory.

Dynamic memory corresponds to virtual memory allocated by an application using memory allocation routines. Unlike file-backed memory, which persists across system reboots, dynamic memory only exists for the lifetime of the application. Dynamic memory is a commonly significant source of memory usage and where memory leaks manifest.

Virtual Allocation routines (`VirtualAlloc`) handle memory allocation requests from a Windows application independent of the application-layer routine used for memory allocation. While not all of the memory allocated by an application may be resident in memory all of the time, analyzing such allocations provides a consistent way to understand the memory usage of an application.

To understand your application's memory usage and find places to make improvements, we recommend capturing a VirtualAllocation trace as described below.

Capture a system trace to analyze memory usage

Recording device activity over a period of time is known as *system tracing*. System tracing produces a trace file that can be used to generate a report and help you identify how to be improve your app's performance.

Traces can vary in length:

- A short running trace can be used to capture the launch of an application. This can include your app's transition to the inactive state, where the application window is

minimized or the application windows is closed while the application process persists.
- A long running trace, typically several minutes in duration, is useful in diagnosing memory leaks. If the memory usage continues to trend up over time, this is usually suggestive of a leak.

There are multiple tools available for monitoring memory use, including:

- Windows Performance Analyzer
- Visual Studio Memory usage diagnostic tool

For the purposes of this article, we will focus on using the Windows Performance Analyzer. To learn more about choosing a tool for profiling the performance of your application, see Choosing among Visual Studio Performance Profiler, Windows Performance Toolkit, and PerfView.

To capture a trace:

1. Open a command line (PowerShell or Command Prompt) in administrator mode. (If not run in admin mode, you may receive error code: 0xc5585011, "Failed to enable the policy to profile system performance.")
2. Enter the command: `wpr -start VirtualAllocation -filemode`
3. Run the scenario that you are investigating. (Launching your application, for example.)
4. Enter the command: `wpr -stop Trace.etl`

Analyze the system trace

In order to find which of your app's functions have allocated memory that you may be able to reduce, you now need to analyze the system trace that was captured. To analyze the trace:

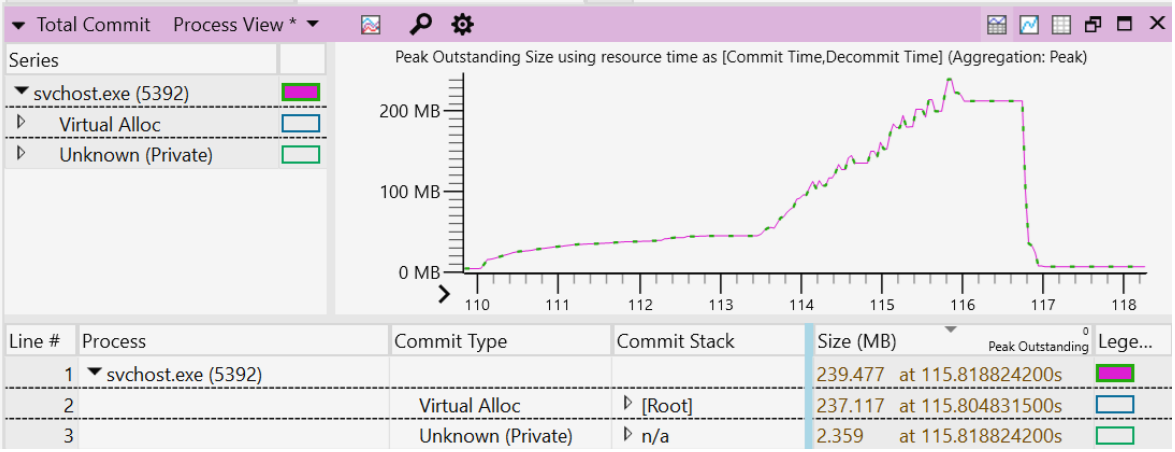
1. Open the trace using Windows Performance Analyzer, by entering the command: `wpa.exe Trace.etl`
2. In the Graph Explorer window, expand the **Memory** section, right-click on the **Total Commit** graph, and select **Add graph to New Analysis View**.
3. Open the **View Editor** by clicking on the **Settings** gear and selecting the following column arrangement: **Process**, **Commit Type**, **Commit Stack** and **Size**.

4. Click on the **Size** column header so that the results are sorted in descending order. The **Commit Stack** shows the code path leading to memory being allocated. These results may help to understand the reason for the allocation. Sorting by size enables you to focus on the larger allocations and investigate whether there is an opportunity to optimize.

5. Filter to the process(es) that you are interested in analyzing by right-clicking on the process and selecting **Filter To Selection**.

6. To zoom in to your region of interest in the viewport, select a range, right-click on the graph, and select **Zoom**.

7. Navigate through the Commit Stack to understand which functions have allocated memory. Commit stacks will need symbols loaded. To load symbols, select **Trace** > **Load symbols** from the top navigation menu bar.



Applying your trace analysis to reduce memory usage

In analyzing the allocated memory, you will find clues to help you decide where memory usage can be minimized.

A few areas to consider in regard to applying your trace analysis toward updating your code to reduce memory usage, include:

- **Reduce memory usage when in the foreground**: Analyzing the memory trace may help you to identify any unnecessary memory use in the foreground and update your code to reduce or remove that usage.

- **Minimizing work while in the background**: The system has policies to age out pages from the process working sets. Using less memory in the background allows the system to be more efficient by keeping less of the application memory

resident. Learn more about how to Improve power consumption and battery life by minimizing background work, which will also translate into using less memory usage while in the background.

- **Release resources in the background**: At runtime, an application may create some memory caches, as well as creating graphics allocations to support its UI. These allocations may be able to be freed when the application is minimized or not visible. An application can register for low-memory notifications to take such action, but a better strategy may be to free memory after a period of not being used, when the application concludes it is inactive. This period of disuse can vary by application, so possible indicators of inactive use can range from a handful of minutes to a ½ hour or more. Care should be taken to balance this kind of memory savings with responsiveness. If a cache is expensive to rebuild, the application can choose to retain it for the lifetime of the application.

- **Ensure your application does not leak memory**: To check for memory leaks, first establish a steady-state benchmark, where the application memory usage plateaus or does not grow beyond a certain value. You can establish this steady-state by continuously using the application or leaving it idle in the background. Using the trace you've captured to identify a possible memory leak, you can find where that memory is being allocated in your code and how it can be freed of use after it has served its purpose. If the memory continues to grow as the application is running, this is a likely indication of a memory leak. Zoom in to the region corresponding to the growth within your trace and carefully analyze the commit stacks.

Efficiently use Disk Space

Disk footprint refers to the size of an application when it's stored in an inactive state (not executing code). If the application takes up a lot of disk footprint it can be an opportunity to optimize.

There are several ways that reducing the disk footprint of your app can improve performance:

- As a disk gets full, the file system can no longer store new content in a contiguous fashion. A full disk becomes fragmented, storing new content on non-contiguous sectors. This translates to longer latency time when that content is accessed from the disk. IO systems will provide much better disk throughput when the content is contiguous and can be accessed sequentially or using larger IOs.

- A full disk may translate to longer write latencies for SSD-based systems. When there are fewer empty cells to absorb writes, a write may incur a read-modify-write

operation, slowing performance.

- A full disk can hinder the ability to update your application. While the OS is resilient and able to keep the system up to date and secure, even with low available disk space, a healthy amount of available disk space for staging the content for your app update will translate to a faster, smoother update experience.

- Requiring a significant amount of a large disk footprint to be accessed at run time will translate to memory use as well. This will impact the responsiveness of your application and the system in general. Additionally, if a small proportion of the disk footprint is required at run time, then the application may be using disk space inefficiently.

A few ways to reduce, or be more efficient with, your disk space include:

- **Apply "pay-for-play" principles to your disk footprint (download only what you need)**: An application may include a broad range of features with not all features applying to all users. This can be one reason for a large on disk footprint. By applying "pay-for-play" principles, you can ask users to select only to download the features that they need, translating to a smaller disk footprint when they download your app. Additional content is made optional for download only when the user has a need for richer capabilities. In addition to features, you may apply the same "pay-for-play" principles to language support. The application can include a subset of popular language choices by default, with additional languages optionally included or dependent on the location set on the user's system.

- **Apply efficient cache sizing**: In some cases, an application can use on-disk caches to make the user experience more responsive. Policies can be set for how your application manages the cache, with an upper limit set on the cache size based on disk capacity and resizing the cache when available space on the disk is low.

- **Apply efficient use of assets**: An application will often include image assets and may consist of a range of image size to support multiple resolutions. Optimizing image size, dimensions, format, and compression for a subset of resolutions, and leveraging scaling to support remaining resolutions, can significantly reduce disk footprint.

- **Investigate binary optimization opportunities**: Tools, such as SizeBench, enable application authors to investigate what contributes to the binary footprint and find opportunities to reduce the amount of disk space used.

Improve power consumption and battery life by minimizing background work

Article • 05/17/2022

This guide will demonstrate how to improve the way that your Windows application consumes power, offering principles to help you improve overall device performance and battery life.

The most basic principles for improving power consumption are to ensure that while your app is in the background, it does not:

- use system resources,
- wake the CPU through timers,
- wake the CPU by waiting for vsync events.

Being "in the background" means that your app is not visible, nor audible, to the user. There should be few, if any, reasons to wake the CPU or utilize system resources while in the background. Checking whether your app is triggering these events and addressing the cause can significantly improve your app's power consumption, battery life, and reduce the carbon emissions that will result from customers using your app.

To check that the CPU is not waking up to do unnecessary work while your app is not in use, you can capture and analyze a trace using Windows Performance Analyzer (WPA). We will walk through the steps explaining how to do so below.

Capture a trace and check for unnecessary work

It is important to set up the correct conditions when running your app before capturing a trace to analyze whether unnecessary work is being performed that can drain power. You also may want to run multiple traces in order to test your app under a variety of conditions.

Setup

1. Get your test device to idle by opening Task Manager and ensuring that CPU utilization is less than 5%. Doing so will minimize measurement interference and provide reasonable size traces.

2. Launch your app and navigate to a view that's expected to be commonly used.

3. Minimize your app. *You may want to repeat the following steps while your app window is fully occluded (blocked from view) behind other windows and when your app is in the foreground, after a period of no interaction by the user, to ensure unnecessary work is not being initiated by the app.

Measure and evaluate CPU use while in the background

1. Open a command line (PowerShell or Command Prompt) in administrator mode. (If not run in admin mode, you may receive error code: 0xc5585011, "Failed to enable the policy to profile system performance.")

2. Enter the command: `wpr -start power -filemode`

3. Leave device idle for 5 minutes.

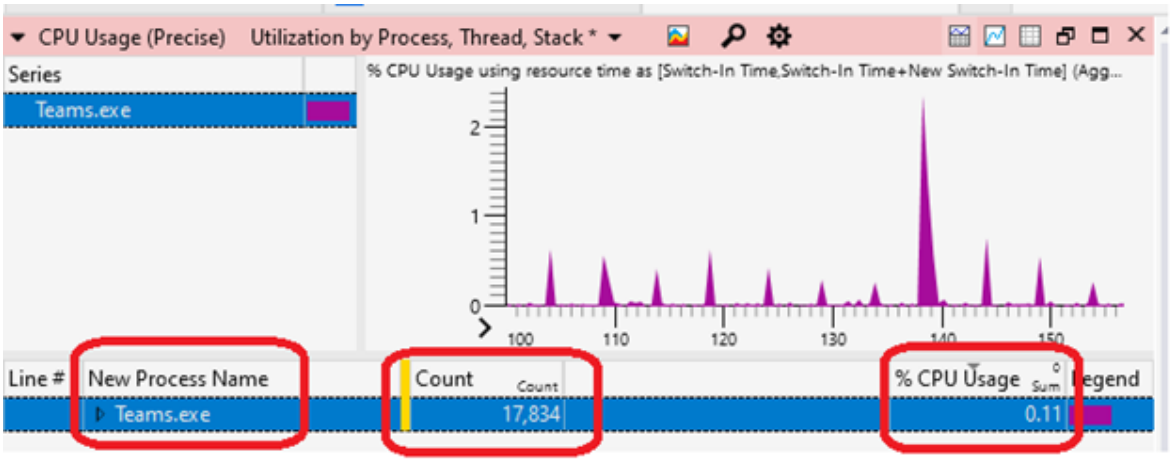
4. Enter the command: `wpr -stop idletrace.etl`

5. To open the trace using Windows Performance Analyzer (WPA), enter the command: `wpa.exe idletrace.etl`

6. Open the **Computation** > **CPU Usage (Precise)** graph.

    - Navigate to your process (or if you have a multi-process model all processes related to your app) and evaluate the Cswitch count, "Utilization by CPU". Ideally these are as close to 0 as possible while the app is in background. Looking at the stacks is a great way to find where resources are being used and how to improve it.

    - Look for excessive wakes by adding a "New Thread Stack" to see which stack the thread woke on.



7. Open the **Computation** > **CPU Usage (Sampled)** graph. Track down CPU usage issues by evaluating where in-code time is being spent executing.

Measure and evaluate vsync waiting while in the background

> **Note**
>
> Focus on basic CPU usage in the previous section before investigating this more advanced scenario.

1. Open a command line (PowerShell or Command Prompt) in administrator mode.
2. Enter the command: `wpr -start gpu -filemode`
3. Leave the device idle for 5 minutes.
4. Enter the command: `wpr -stop gputrace.etl`
5. To open the trace using Windows Performance Analyzer (WPA), enter the command: `wpa.exe gputrace.etl`
6. Open the **System Activity** > **Generic events** graph.
   - Filter to "Microsoft-Windows-Dxgkrnl" events.
   - Drag the **Process** column over to be the 2nd column.
   - Check if you are calling into WaitForVsync. For example, through APIs like IDXGIOutput::WaitForVBlank (dxgi.h) through the `WaitForVerticalBlankEventInternal` event.

Improve the responsiveness of your Windows app

Article • 05/17/2022

This guide will help you to improve the responsiveness of your Windows application by optimizing latency for launch and key interactions. Quick, responsive interactions (otherwise known as low-latency interactions) creates a better user experience. Understanding interaction expectations, measuring current durations, and setting goals for improvement depending on the interaction class can lead to significant improvements in your users experience and satisfaction.

Step by step guide to optimizing interactions for responsive behavior

Customers can feel when an application launch, menu navigation, or page/content load is slow. They have come to expect a fast, seamless experience and we have shared some steps and guidance to better understand those expectations below.

The basic steps to drive latency optimization are:

1. Define the scenario and add TraceLogging events.

   Make a list of the key interactions that a user will go through while using your app, such as launch, opening a menu, navigating to a new page and rendering content, etc. For each of these interactions, add a start event and stop event to be used for measurement and analysis. Learn more about how to add TraceLogging, a format for self-describing Event Tracing for Windows (ETW).

2. Set goals based on the interaction class.

   Users have different expectations for an app's performance and responsiveness depending on the type of interaction. For example, how quickly an app launches versus how quickly a page loads. Think of the acceptable range of elapsed time that it takes for users to complete the key interactions in your app. This may range from 200 milliseconds (ms) to 5 seconds (sec). Then assign each task an interaction class label with an associated goal. Below are a few basic guidelines, along with suggestions for how you might include a user interface (UI) to improve the perception of responsiveness:

Expand table

Interaction class label	User perception	Range of delay	Examples	Suggested UI
Fast	Minimally noticeable delay	100 - 200 milliseconds	Open app bar, right click menu	
Interactive	Quick, but not fast	300 - 500 ms	Exit an app, display cached search results	
Pause	Not quick, but feels responsive	500 ms - 1 sec	Navigate to a different page, resume the app from a suspended state, display web search results	An entrance animation (e.g. fly in new content) may be used to mask the time taken for this scenario.
Wait	Not quick due to amount of work for scenario	1 - 3 sec	Launching the app	A spinning/waiting cursor may be used to note progress. Both an exit and entrance animation (e.g. fly old page out, fly new page in) may be used to mask the time taken for this scenario.
Long wait	No longer feels responsive	2 - 5 sec	Large app launches (use extended splash screen), starting an HD video stream	A "loading UI" is displayed – where possible, include a "cancel" option for the user. The loading UI should appear within the Fast interaction class. The loading UI does not need to display a percentage or time remaining.
Captive	A long wait – reserved for unavoidably long/complex scenarios	5 - 10 sec	System login	A "loading UI" or dialog is displayed – where possible, include a "cancel" option for the user. The dialog should appear within the Fast interaction class. The dialog should display a percentage or time remaining if this would provide useful context to the user.

Interaction class label	User perception	Range of delay	Examples	Suggested UI
Long-running	Long operations – users will probably multitask (switch away during operation)	10 - 30+ sec	Installing new features or updates, large file downloads	UI should be designed to reflect multitasking possibility. A progress dialog should be displayed including an estimate of completion (percentage, time remaining, etc.). Alternatively, the UI can minimize completely and only notify the user when the scenario has finished by using a toast notification.

3. To check the exact durations for specific interactions, you can capture and analyze a trace using Windows Performance Analyzer (WPA).

    - Before capturing your trace, get your test device to idle by opening Task Manager and ensuring that CPU utilization is less than 5%. Doing so will minimize measurement interference and provide reasonable size traces. This will help you to better isolate the interaction that you aim to measure.
    - To capture a trace, open a command line (PowerShell or Command Prompt) in administrator mode.
    - Enter the command: `wpr -start GeneralProfile -filemode`
    - Run the interaction scenario on your app.
    - Enter the command: `wpr -stop Trace.etl`

4. Analyze the trace and find improvement opportunities.

    Analyze the duration of each key interaction supported by your app by opening the trace that you just captured in Windows Performance Analyzer (WPA).

    - To open the trace in WPA, in your command line, enter: `wpa.exe Trace.etl`
    - Expand the **System Activity** dropdown and double-click on "Generic Events" to open the analysis view.
    - Choose the event series related to your application and expand the "Provider Name" dropdown until you are able to find the Process, Task Name, and Event name associated with the key interaction you are seeking. The duration of the interaction event will be listed in the **Time** column, as well as in the graph, showing **Duration**, **Start Time**, and **End Time**.

If the duration from your trace does not meet the interaction class goals (ex: 500ms), identify the key threads for your App (likely the UI thread), and look at the top stacks for CPU usage and waits. *Remember that as you perform the analysis, some issues may not be specific to your own application's code.

WinUI performance optimization

Article • 03/22/2024

This topic describes how to use performance monitoring tools from the Windows Performance Toolkit to produce in-depth performance profiles for WinUI applications.

How do I use the Windows Performance Recorder to monitor WinUI apps?

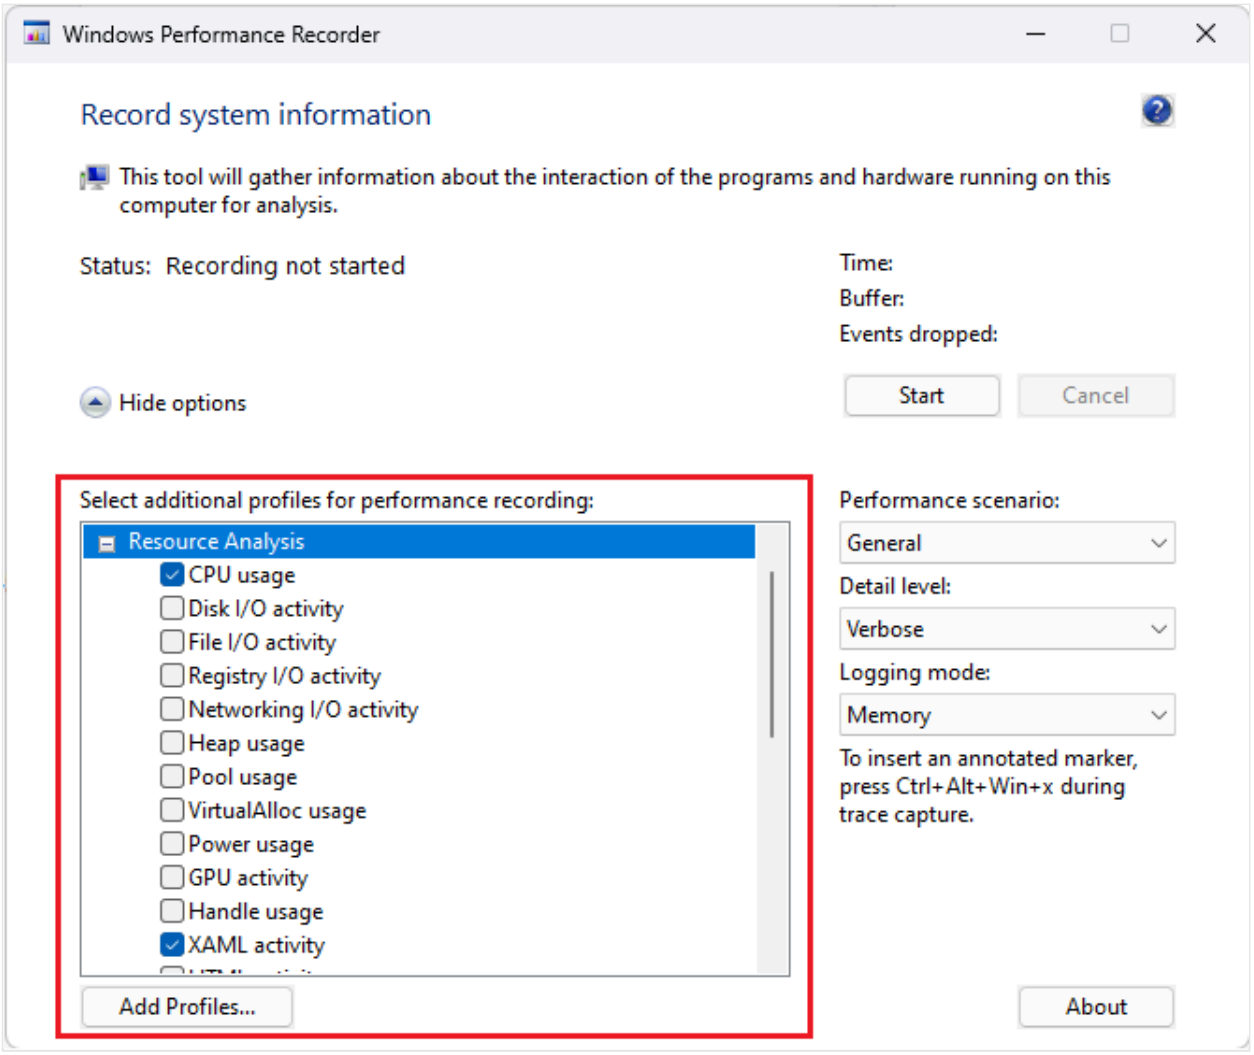
The Windows Performance Recorder (WPR) can be used to create detailed Event Tracing for Windows (ETW) recordings of system and application behavior and resource usage based on built-in profiles. These ETW recordings can then be processed by the Windows Performance Analyzer (WPA) to produce a set of graphs and tables for easier consumption and in-depth analysis of CPU usage, power issues, poor system or application performance, and other performance issues.

> **Note**
>
> While there are both GUI and command-line versions of the WPR, this topic refers only to the GUI version (see **Introduction to WPR** for more details on both versions).

WPR profiles

WPR profiles are used to collect information on various aspects and behaviors of your app.

In the following image, the Windows Performance Recorder window is shown with the "CPU usage" profile (CPU utilization for each CPU on the system) and "XAML activity" profile (events from XAML-related providers, such as WinUI) selected.

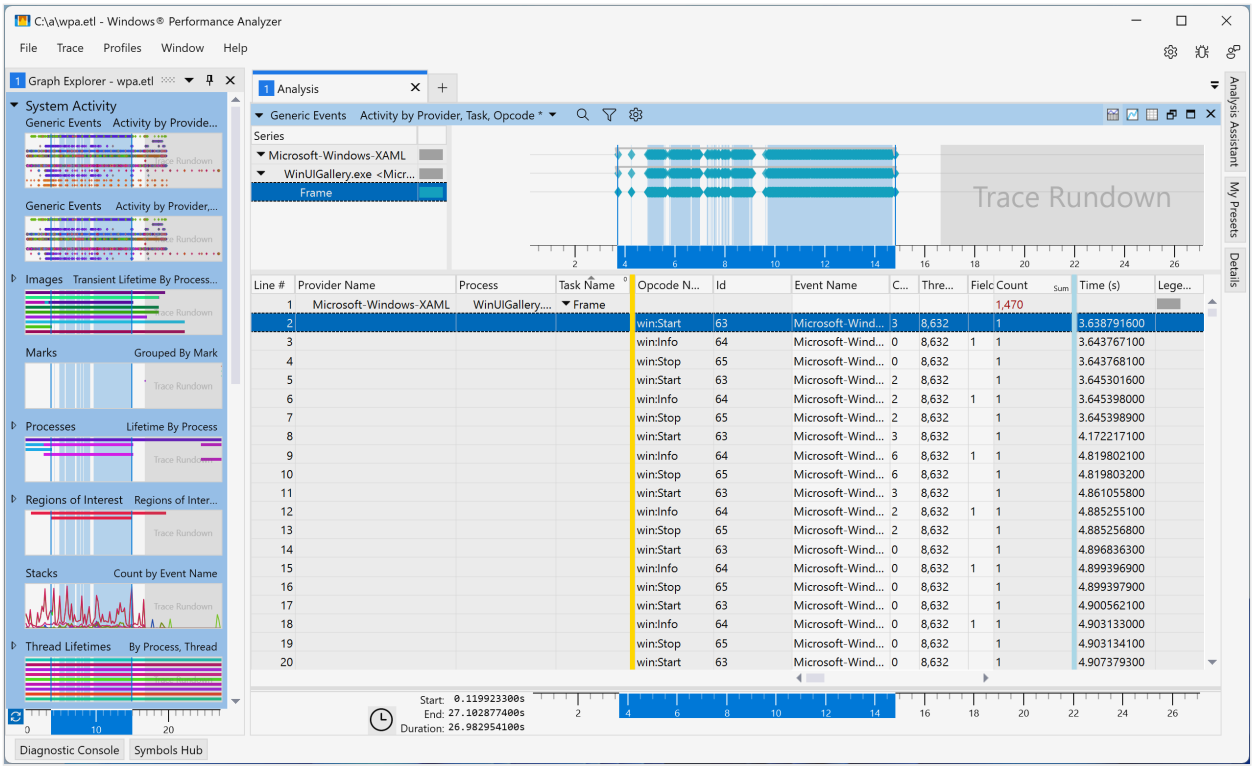


How do I use the Windows Performance Analyzer with WinUI apps?

WinUI is a declarative, retained-mode API where the app describes a tree of UIElements and WinUI runs layout and renders it. This is done on the UI thread in batches called "frames", which should complete quickly, ideally within one refresh interval of the display. When frames run long, not only does it delay updates from making it to the display, but it also prevents the UI thread from handling input. Slow frames, while not the only reason for responsiveness problems, are one of the most common.

Install the "XAML Frame Analysis" plugin

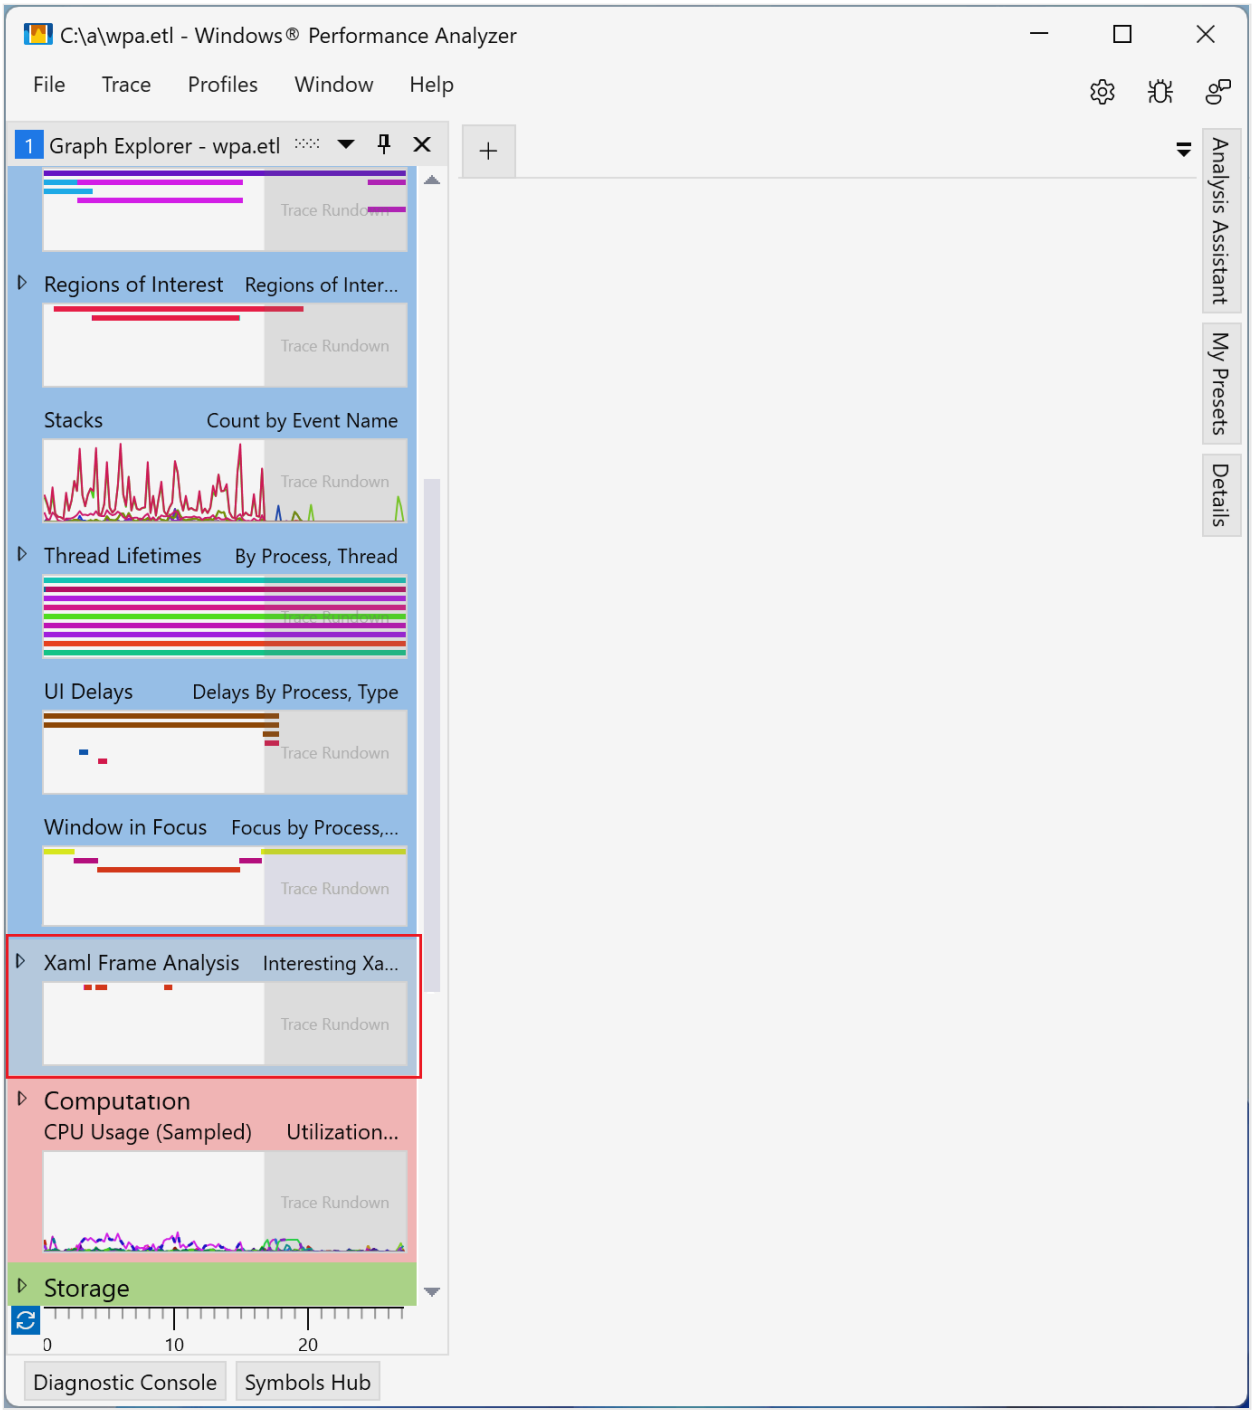
WinUI logs ETW events that track the start and stop of each frame (shown in the following screenshot of the WPA "Generic Events" table). However, because the duration of each frame needs to be calculated manually, it's difficult to identify slow frame occurrences.



To address this issue, a new "XAML Frame Analysis" table plugin is included with the Windows Assessment Toolkit (ADK) preview, build 26020 and later. This table calculates and shows the duration of each frame (along with other time-consuming operations).

> **Note**
>
> While only the preview version of the Windows Performance Analyzer (WPA) has the "XAML Frame Analysis" table, the version of WPR used to take the trace does not matter.

Once the ADK preview is installed, the "XAML Frame Analysis" table must be enabled by editing the "perfcore.ini" config file in the WPA folder (typically, C:\Program Files (x86)\Windows Kits\10\Windows Performance Toolkit). To do this, close any open instances of WPA, open "perfcore.ini" in a text editor, add `perf_xaml.dll` to the list of dlls, and save and close the file. Restart WPA, which should now show the "XAML Frame Analysis" graph at the bottom of the System Activity section.



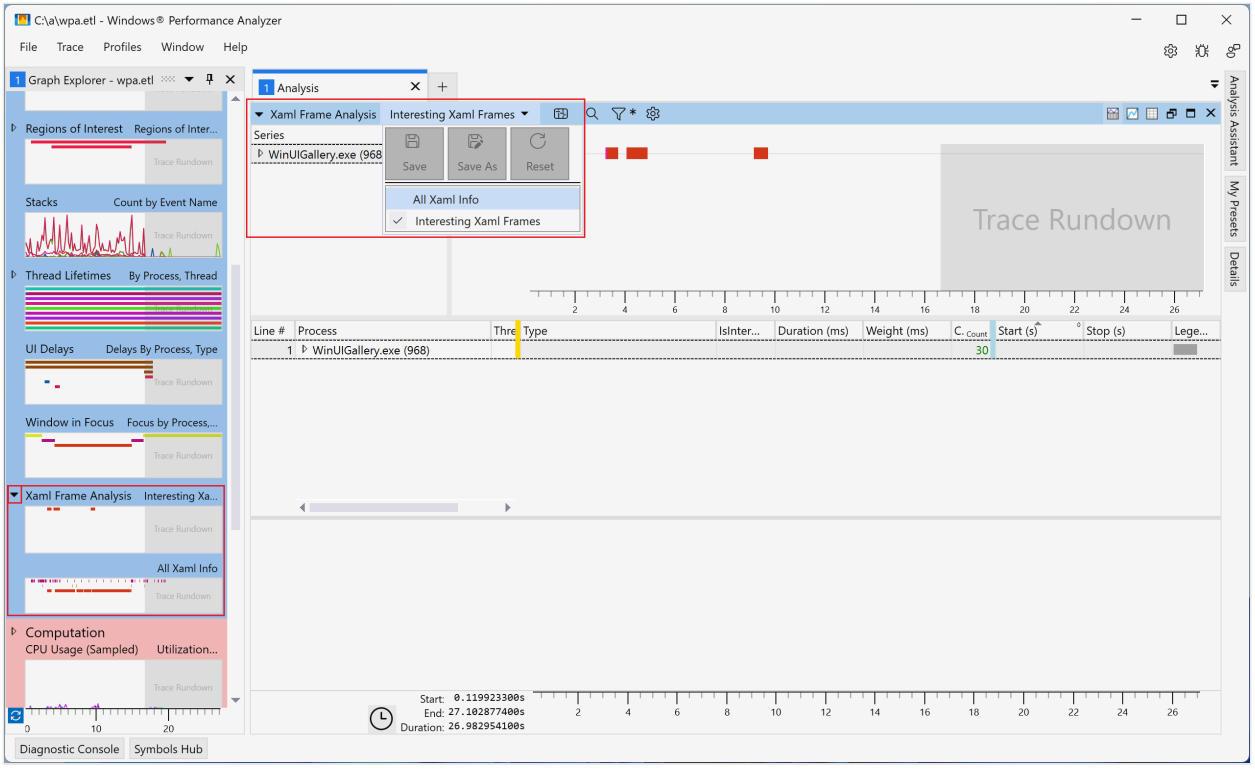
Use the "XAML Frame Analysis" plugin

The Xaml Frame Analysis supports two views (both views show the same columns):

- "Interesting Xaml Frames" (default) - Shows WinUI frames based on heuristics that identify those most likely to cause responsiveness problems. These correspond to regions that start with operations like WinUI initialization, frame navigation, or flyout display, and stop with the end of the next frame. These scenarios typically involve extensive changes to the UIElement tree and are the most susceptible to performance problems.
- "All Xaml Info" - Shows all WinUI frames from all process found in the trace. For operations like a frame or a layout pass, the plugin automatically computes and

displays the durations based on the Start and Stop events.

The following screenshot highlights how to switch between Xaml Frame Analysis views.



Both Xaml Frame Analysis views include the following columns:

Expand table

Title	Value
Process	Process name and ID
Thread ID	Thread ID
Type	Describes the event corresponding to the row. Possible values include: • *WXM::InitializeForCurrentThread* - A call to WindowsXamlManager.InitializeForCurrentThread. Initializes WinUI on the thread. • *DWXS::Initialize* - A call to DesktopWindowXamlSource.Initialize. Initializes a WinUI island. • *Frame* - A frame on the UI thread. Runs layout and renders changes to the tree since the previous frame. • *Create graphics device* - Create a D3D and a D2D device for WinUI. Occurs on a background thread. • *UpdateLayout* - A layout pass on the UI thread. Occurs as part of a frame, but can also be triggered by the app through UIElement.UpdateLayout. • *Frame::Navigating* - WinUI raises the Frame.Navigating event. • *Frame::Navigated* - WinUI raises the Frame.Navigated event. • *Hwnd Focus* - The active hwnd changed.

Title	Value
	• *Region of Interest* - A region computed by the plugin for interesting scenarios. Starts after events such as WinUI initialization, frame navigation, and opening menus. Stops at the end of the next frame.
IsInteresting	Whether the row is considered interesting. Only interesting rows show up in the Interesting Xaml Frames view.
Duration (ms)	The duration of the row. Computed from Start and Stop events.
Weight (ms)	The actual CPU execution time corresponding to the duration.
Start (s)	The time of the Start event
Stop (s)	The time of the Stop event

Columns can be sorted by Type or Duration to help identify potential issues such as the most expensive, longest duration frames in the trace (see following image). You can also drill down into specific rows to identify the expensive operations and potential optimizations.

Security and identity

Article • 03/19/2025

This article provides an index of development features that are related to scenarios involving security and identity in Windows apps.

Windows OS features

Windows provides a wide variety of APIs related to security and identity scenarios for apps. These features are available via a combination of Windows App SDK, Windows Runtime (WinRT), and Win32 (C++ and COM) APIs provided by the Windows SDK.

Windows App SDK APIs

The Windows App SDK provides APIs related to OAuth 2.0 authorization flows. There are also a few helper APIs in the Microsoft.Windows.Security.AccessControl namespace. These APIs are related to named object sharing between packaged apps and Win32 applications.

Expand table

Article	Description
Implement OAuth 2.0 functionality in Windows apps	The new OAuth2Manager in Windows App SDK enables desktop applications such as WinUI to seamlessly perform OAuth 2.0 authentication in Windows apps. This article describes how to implement OAuth 2.0 with the Windows App SDK.

WinRT APIs

Credential locker for Windows apps

Article • 08/09/2024

This article describes how Windows apps can use the Credential Locker to securely store and retrieve user credentials, and roam them between devices with the user's Microsoft account.

The Windows Runtime (WinRT) APIs for Credential Locker access are part of the Windows Software Development Kit (SDK). These APIs were created for use in Universal Windows Platform (UWP) apps, but they can also be used in WinUI apps or in packaged desktop apps, including WPF and Windows Forms. For more information about using WinRT APIs in your Windows desktop app, see Call Windows Runtime APIs in desktop apps.

Overview of the sample scenario

For example, you have an app that connects to a service to access protected resources such as media files, or social networking. Your service requires login information for each user. You've built UI into your app that gets the username and password for the user, which is then used to log the user into the service. Using the Credential Locker API, you can store the username and password for your user and easily retrieve them and log the user in automatically the next time they open your app, regardless of what device they're on.

User credentials stored in the Credential Locker do *not* expire, are *not* affected by the ApplicationData.RoamingStorageQuota, and will *not* be cleared out due to inactivity like traditional roaming data. However, you can only store up to 20 credentials per app in the Credential Locker.

Credential Locker works a little differently for domain accounts. If there are credentials stored with your Microsoft account, and you associate that account with a domain account (such as the account that you use at work), your credentials will roam to that domain account. However, any new credentials added when signed on with the domain account won't roam. This ensures that private credentials for the domain aren't exposed outside of the domain.

Storing user credentials

1. Obtain a reference to the Credential Locker using the PasswordVault object from the Windows.Security.Credentials namespace.

2. Create a PasswordCredential object that contains an identifier for your app, the username and the password, and pass that to the PasswordVault.Add method to add the credential to the locker.

```cs
var vault = new Windows.Security.Credentials.PasswordVault();
vault.Add(new Windows.Security.Credentials.PasswordCredential(
    "My App", username, password));
```

Retrieving user credentials

You have several options for retrieving user credentials from the Credential Locker after you have a reference to the PasswordVault object.

- You can retrieve all the credentials the user has supplied for your app in the locker with the PasswordVault.RetrieveAll method.
- If you know the username for the stored credentials, you can retrieve all the credentials for that username with the PasswordVault.FindAllByUserName method.
- If you know the resource name for the stored credentials, you can retrieve all the credentials for that resource name with the PasswordVault.FindAllByResource method.
- Finally, if you know both the username and the resource name for a credential, you can retrieve just that credential with the PasswordVault.Retrieve method.

Let's look at an example where we have stored the resource name globally in an app and we log the user on automatically if we find a credential for them. If we find multiple credentials for the same user, we ask the user to select a default credential to use when logging on.

```cs
private string resourceName = "My App";
private string defaultUserName;

private void Login()
{
    var loginCredential = GetCredentialFromLocker();

    if (loginCredential != null)
    {
        // There is a credential stored in the locker.
        // Populate the Password property of the credential
        // for automatic login.
        loginCredential.RetrievePassword();
    }
```

```
    else
    {
        // There is no credential stored in the locker.
        // Display UI to get user credentials.
        loginCredential = GetLoginCredentialUI();
    }

    // Log the user in.
    ServerLogin(loginCredential.UserName, loginCredential.Password);
}

private Windows.Security.Credentials.PasswordCredential
GetCredentialFromLocker()
{
    Windows.Security.Credentials.PasswordCredential credential = null;

    var vault = new Windows.Security.Credentials.PasswordVault();

    IReadOnlyList<PasswordCredential> credentialList = null;

    try
    {
        credentialList = vault.FindAllByResource(resourceName);
    }
    catch(Exception)
    {
        return null;
    }

    if (credentialList.Count > 0)
    {
        if (credentialList.Count == 1)
        {
            credential = credentialList[0];
        }
        else
        {
            // When there are multiple usernames,
            // retrieve the default username. If one doesn't
            // exist, then display UI to have the user select
            // a default username.
            defaultUserName = GetDefaultUserNameUI();

            credential = vault.Retrieve(resourceName, defaultUserName);
        }
    }

    return credential;
}
```

Deleting user credentials

Deleting user credentials in the Credential Locker is also a quick, two-step process.

1. Obtain a reference to the Credential Locker using the PasswordVault object from the Windows.Security.Credentials namespace.
2. Pass the credential you want to delete to the PasswordVault.Remove method.

```cs
var vault = new Windows.Security.Credentials.PasswordVault();
vault.Remove(new Windows.Security.Credentials.PasswordCredential(
    "My App", username, password));
```

Best practices

Only use the credential locker for passwords and not for larger data blobs.

Save passwords in the credential locker only if the following criteria are met:

- The user has successfully signed in.
- The user has opted to save passwords.

Never store credentials in plain-text using app data or roaming settings.

Fingerprint biometrics

Article • 08/09/2024

This article explains how to add fingerprint biometrics to your Windows app, including a request for fingerprint authentication when the user must consent to a particular action increases the security of your app. For example, you could require fingerprint authentication before authorizing an in-app purchase, or access to restricted resources. Fingerprint authentication is managed using the UserConsentVerifier class in the Windows.Security.Credentials.UI namespace.

The Windows Runtime (WinRT) APIs for fingerprint biometrics are part of the Windows Software Development Kit (SDK). These APIs were created for use in Universal Windows Platform (UWP) apps, but they can also be used in WinUI apps or in packaged desktop apps, including WPF and Windows Forms. For more information about using WinRT APIs in your Windows desktop app, see Call Windows Runtime APIs in desktop apps.

Check the device for a fingerprint reader

To find out whether the device has a fingerprint reader, call UserConsentVerifier.CheckAvailabilityAsync. Even if a device supports fingerprint authentication, your app should still provide users with an option in Settings to enable or disable it.

cs

```
public async System.Threading.Tasks.Task<string>
CheckFingerprintAvailability()
{
    string returnMessage = "";

    try
    {
        // Check the availability of fingerprint authentication.
        var ucvAvailability = await
Windows.Security.Credentials.UI.UserConsentVerifier.CheckAvailabilityAsync()
;

        switch (ucvAvailability)
        {
            case
Windows.Security.Credentials.UI.UserConsentVerifierAvailability.Available:
                returnMessage = "Fingerprint verification is available.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerifierAvailability.DeviceBusy:
```

```
                returnMessage = "Biometric device is busy.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerifierAvailability.DeviceNotPre
sent:
                returnMessage = "No biometric device found.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerifierAvailability.DisabledByPo
licy:
                returnMessage = "Biometric verification is disabled by
policy.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerifierAvailability.NotConfigure
dForUser:
                returnMessage = "The user has no fingerprints registered.
Please add a fingerprint to the " +
                                "fingerprint database and try again.";
                break;
            default:
                returnMessage = "Fingerprints verification is currently
unavailable.";
                break;
        }
    }
    catch (Exception ex)
    {
        returnMessage = $"Fingerprint authentication availability check
failed: {ex.ToString()}";
    }

    return returnMessage;
}
```

Request consent and return results

1. To request user consent from a fingerprint scan, call the UserConsentVerifier.RequestVerificationAsync method. For fingerprint authentication to work, the user must have previously added a fingerprint "signature" to the fingerprint database.
2. When you call the UserConsentVerifier.RequestVerificationAsync, the user is presented with a modal dialog requesting a fingerprint scan. You can supply a message to the **UserConsentVerifier.RequestVerificationAsync** method that will be displayed to the user as part of the modal dialog, as shown in the following image.

```
cs
```

```
private async System.Threading.Tasks.Task<string> RequestConsent(string
userMessage)
{
    string returnMessage;

    if (String.IsNullOrEmpty(userMessage))
    {
        userMessage = "Please provide fingerprint verification.";
    }

    try
    {
        // Request the logged on user's consent via fingerprint swipe.
        var consentResult = await
Windows.Security.Credentials.UI.UserConsentVerifier.RequestVerificationAsync
(userMessage);

        switch (consentResult)
        {
            case
Windows.Security.Credentials.UI.UserConsentVerificationResult.Verified:
                returnMessage = "Fingerprint verified.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerificationResult.DeviceBusy:
                returnMessage = "Biometric device is busy.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerificationResult.DeviceNotPrese
nt:
                returnMessage = "No biometric device found.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerificationResult.DisabledByPoli
cy:
                returnMessage = "Biometric verification is disabled by
policy.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerificationResult.NotConfiguredF
orUser:
                returnMessage = "The user has no fingerprints registered.
Please add a fingerprint to the " +
                                "fingerprint database and try again.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerificationResult.RetriesExhaust
ed:
                returnMessage = "There have been too many failed attempts.
Fingerprint authentication canceled.";
                break;
            case
Windows.Security.Credentials.UI.UserConsentVerificationResult.Canceled:
                returnMessage = "Fingerprint authentication canceled.";
```

```
                break;
            default:
                returnMessage = "Fingerprint authentication is currently
unavailable.";
                break;
        }
    }
    catch (Exception ex)
    {
        returnMessage = $"Fingerprint authentication failed:
{ex.ToString()}";
    }

    return returnMessage;
}
```

Intro to passkeys

Article • 09/09/2024

Learn about simpler, stronger, passwordless sign-ins. Passkeys can use your fingerprint or other biometric to log you into your websites and apps, just like unlocking your device.

Passkeys—based on Fast IDentity Online (FIDO) standards—are a replacement for passwords. Using a passkey to sign in to websites and apps across your devices is faster, easier, and more secure. Unlike a password, a passkey is always strong and phishing-resistant.

Some aspects of passkeys:

- Simplify account registration for apps and websites.
- Are easy to use.
- Work across most of your devices.
- And even work on other devices in physical proximity.

Why passkeys?

The motivation for using passkeys is, initially, an acknowledgment of the following considerations related to passwords.

Some aspects of passwords:

- They're knowledge-based.
- Can be difficult to use and to remember.
- Can be easy to phish, harvest, and replay (a very high percentage of organizations experience phishing attacks each year).
- Are a root cause of the vast majority of data breaches.

And also consider:

- There's a labor cost involved in each password reset.
- Nearly all users have a large number of online accounts.
- Most passwords are reused.

So passkeys are the answer to those issues. Passkeys address the security problems, and they're suitable for large-scale use by consumers.

Passkey protocols don't provide information that can be used by different online services to collaborate and track a user across the services. Biometric information, if

used, never leaves the user's device. With passkeys, there are no shared secrets.

Passkeys optimize access and usability for authentication

Your organization can deploy passkeys across a variety of use cases, including users signing in to your Windows apps, and users authenticating themselves to your websites. Passkeys enable users to access their sign-in credentials on many of their devices. Device-bound passkeys are bound to a FIDO security key or platform.

How do users use passkeys?

A relying party (RP)—such as a website—that wants to use passkeys first sets up a credential with you. So a user can first get a passkey from the website (instead of or in addition to a password), and then subsequently when the user wants to sign in, they can approve the use of their passkey for that site.

When a user signs in to an app or to a website by using a passkey, they approve the sign-in with the same biometric or PIN that they use to unlock the device (phone, computer, or security key). The app or website can use that mechanism instead of the traditional username and password. For example, if your passkey is stored with Windows Hello, then you can use your face, fingerprint, or PIN that you used with Windows Hello, to approve the use of that passkey.

The workflow is described in more detail in Implement passkeys and in Design guidelines for passkeys.

The benefits

Here's what that means for:

- **User experience**. The user experience (UX) will be familiar and consistent across many of your users' devices—a simple verification of their fingerprint or face, or a device PIN. The same simple action that consumers take multiple times each day to unlock their devices.
- **Security**. Passkeys are based on FIDO Authentication, which is proven to be resistant to threats of phishing, credential stuffing, and other remote attacks. Also, service providers can offer passkeys without needing passwords as an alternative sign-in or account recovery method.

Passkeys reduce the risk of phishing, and eliminate credential reuse. They also help to speed up sign-ins, improve service delivery, and lower costs. Faster, more secure, and more successful sign-ins means less breach risk, more transactions, better service delivery, and fewer credential resets and helpdesk calls for account recovery.

The FIDO passkey logo

Look for the FIDO passkey logo on sites that allow you to use passkeys instead of passwords. If you're a service provider interested in using this logo, then visit FIDO Trademark and Service Mark Usage Agreement for Websites to agree to terms, and to download the logo files.

Implement passkeys

Article • 09/09/2024

Also see Intro to passkeys

This topic describes how to implement passkey sign-ins across online, enterprise, and government applications, and for payments. You can implement passkeys (instead of passwords) to provide your websites and apps with user-friendly and cryptographically secure sign-ins—all courtesy of the public WebAuthn API.

Consumer service providers, enterprises, and governments around the world are moving from forms authentication (such as passwords and SMS OTPs) to passkey-based sign-ins. Every organization has its own varying use cases and business requirements.

How passkeys work

Passkeys use standard public key cryptography techniques. When a user registers with an online service, the user's client device creates a new cryptographic key pair that is bound to the web service domain. The device retains the private key, and registers the public key with the online service. These cryptographic key pairs, called passkeys, are unique and bound to the online service domain.

The way authentication works is that the user's device must prove possession of the private key by presenting a challenge for sign-in to be completed. This occurs after the user approves the sign-in locally on their device, via quick and easy entry of a biometric (such as a thumbprint), or local PIN, or touch of a FIDO security key. Sign-in is completed via a challenge-response from the user's device and the online service. The service doesn't see or ever store the private key.

To enroll a passkey with an online service:

- The user is prompted to create a passkey.
- The user verifies the passkey creation via a local authentication method (for example, biometrics).
- The user's device creates a new public/private key pair (a passkey) that's unique for the local device, the online service, and the user's account.
- The public key (and *only* that) is sent to the online service, and is associated with the user's account.

To subsequently sign in by using a passkey:

- The user is prompted to sign in by using a passkey.

- The user verifies the sign-in-with-passkey via a local authentication method (for example, biometrics).
- The device uses the user's account identifier (provided by the service) to select the correct key, and sign the service's challenge.
- The client device sends the signed challenge back to the service, which verifies it with the stored public key, and signs the user in.

Implement passkeys for consumers, enterprise, government, or payments

This section is for you if you're considering implementing passkeys.

If you're new to FIDO, then we recommend that you first review the User Authentication Specifications Overview. Then, you can access the latest versions of the FIDO Alliance user authentication specifications at Download Authentication Specifications.

The FIDO Certified Showcase highlights FIDO Alliance members and their FIDO Certified solutions. It's a great resource if you're looking to deploy FIDO.

The FIDO Enterprise Deployment Working Group (EDWG) has developed a series of white papers that provide guidance for leaders and practitioners considering passkeys—scaling from SMBs to large enterprises. To understand the key decision points, see Enterprise.

If your field is along the lines of citizen services or government employee applications, then see Government.

For more info about payment scenarios that are ideal for passkeys, see Payments.

Design guidelines for passkeys

Article • 09/09/2024

There are 14 design patterns for passkeys. You can get started with two essential patterns, and then add optional patterns to your passkeys deployment based on your unique business needs.

Essential patterns

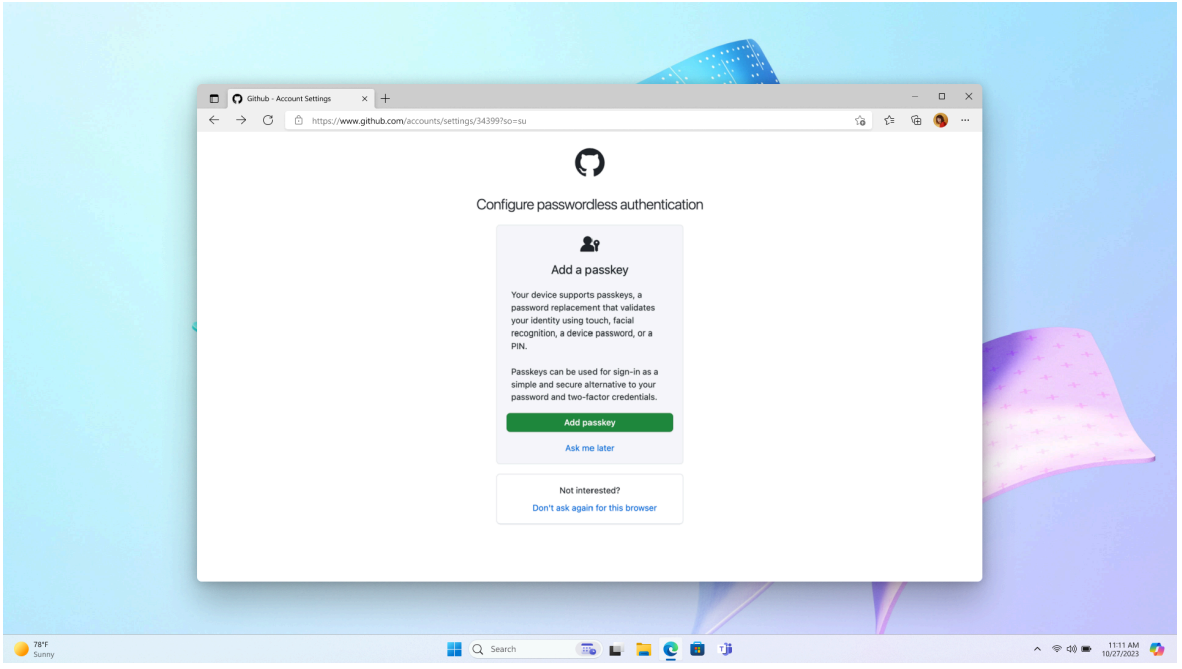
The two essential (foundational) patterns are that:

- A user needs first to *create* a passkey (and view/manage it),
- and then the user can *sign in* with it.

Every rollout of passkeys should make use of these patterns.

Pattern 1: Create, view, and manage passkeys in account settings

- If a passkey doesn't exist for the current user, then display the passkey creation prompt, like this:

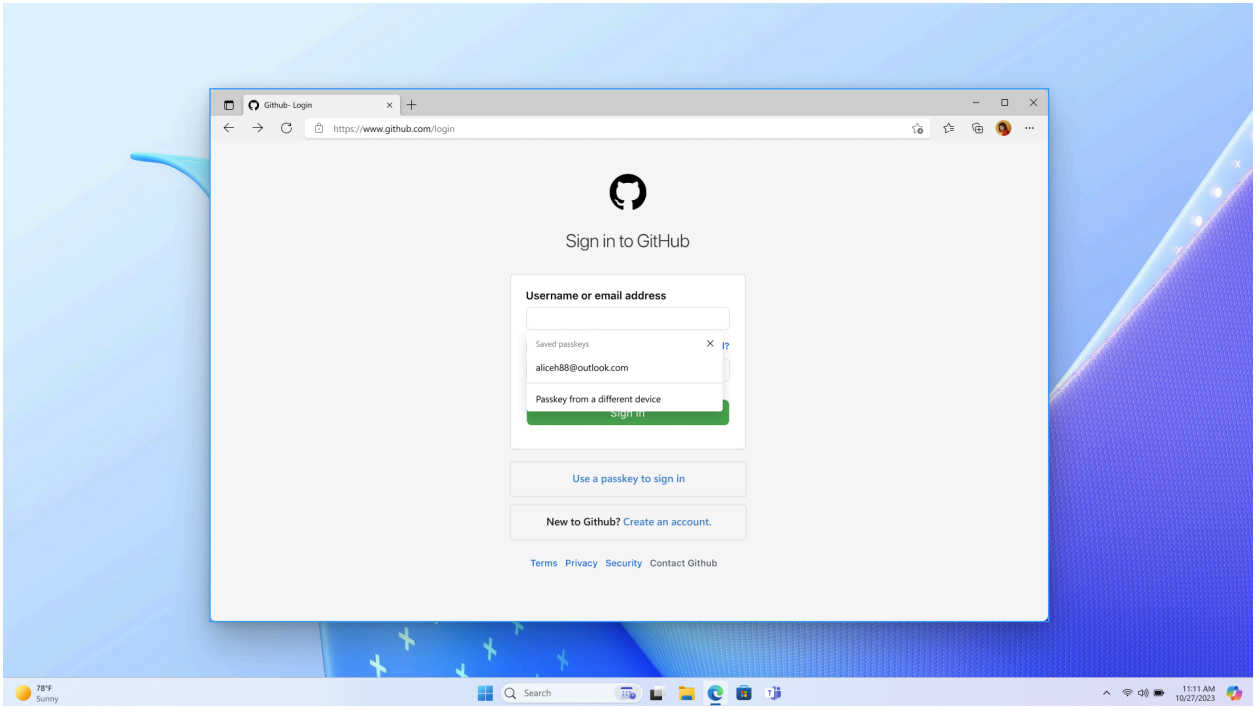


Pattern 2: Sign in with a passkey

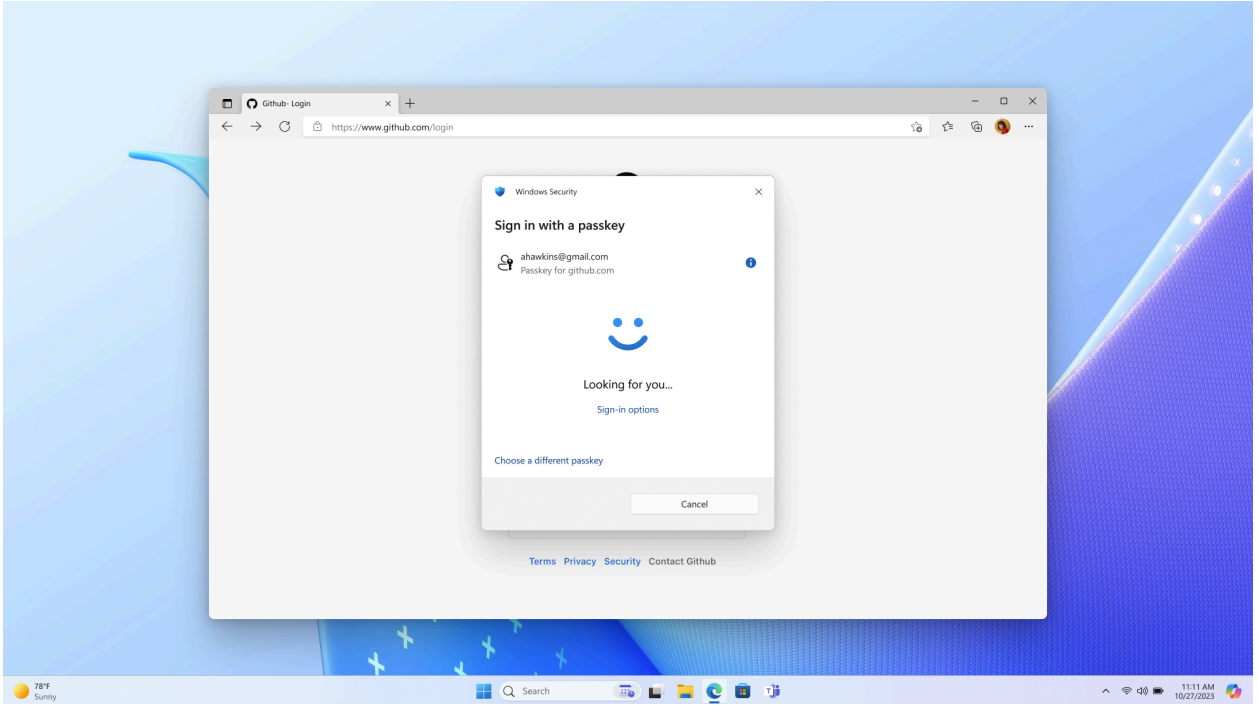
- Enable autofill by adding `autocomplete="webauthn"` to your **username** input field.

- Support graceful fallback to other sign-in methods. Allow users to enter some different credential (not a passkey) to sign in or to create an account.
- Research explored users' success and satisfaction with: a dedicated "Sign in with a passkey" link, buttons, and autofill. Testing indicated that autofill ensured the highest success for people to sign in with a passkey.

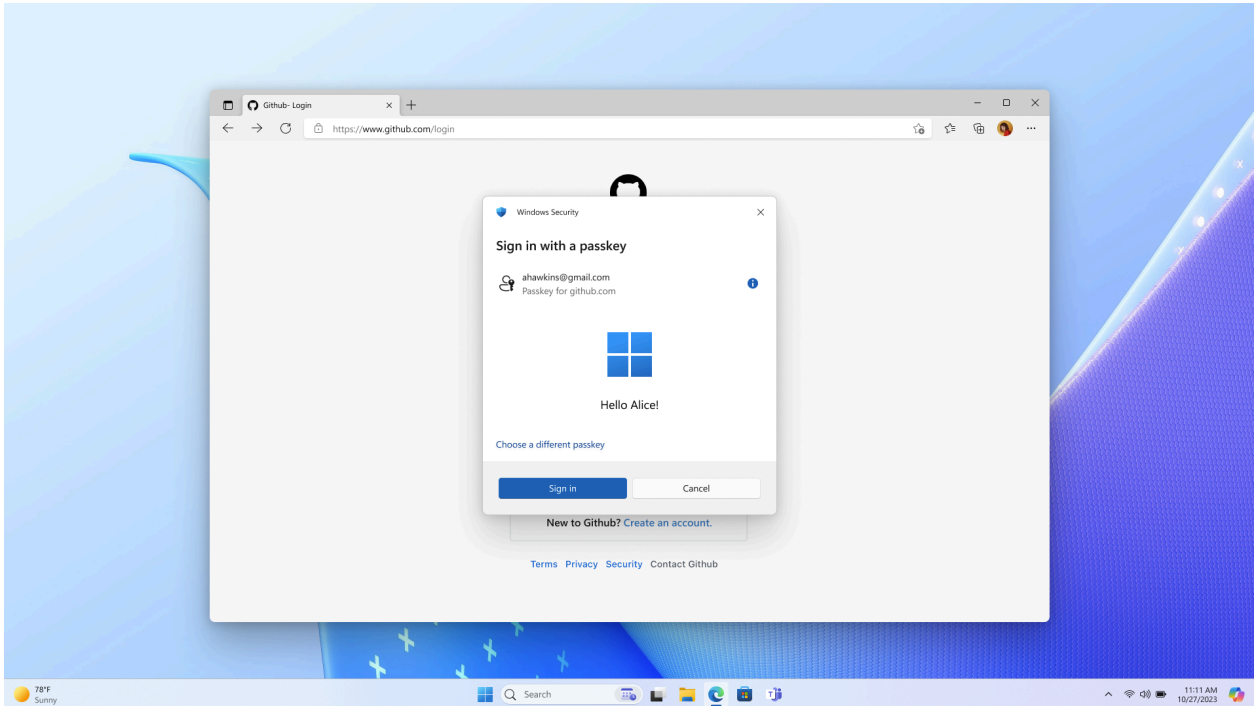
Step 2.1: Login page



Step 2.2: Passkey sign-in prompt with lock screen



Step 2.3: Login success with Windows Hello



UI text, research, and rollout

Here are some user-tested button labels and phrases. Copy and edit them to suit your needs.

With passkeys, you don't need to remember complex passwords.

What are passkeys? Passkeys are encrypted digital keys you create using your fingerprint, face, or screen lock.

Where are passkeys saved? Passkeys are saved in your password manager, so you can sign in on other devices.

Research indicates that your users will appreciate the option to create a passkey for their account *at any point* within the account settings workflow. Candidates described an account settings UI as an intuitive and useful place to proactively learn about and update their authentication settings.

The research also indicates that users seek to understand the nature and value of passkeys. Vague or technical explanations often confuse them and lead them to abandon creating a passkey. Familiar biometric iconography, and brief messaging that compares passkeys to known technologies, is most effective at providing the right level of information. For users who already have a passkey, the passkey card(s) afford them an unmistakable object in the interface that they later visualize and then find in your account settings UI. They use that to get actionable information about the passkey.

On your homepage, we recommend that you offer one affordance for both sign-in and account creation. Research indicates that the action of creating an account is more discoverable that way, rather than surfacing the account creation option *after* the user has signed in. Also, some users report that occasionally they're uncertain whether they have an account—so a multipurpose button serves their needs.

Rollout

Passkeys might require specific hardware or software support on users' devices. Ensure that users are aware of the compatibility requirements for using passkeys, and provide guidance on compatible devices and browsers including Windows and Edge.

In the context of native mobile apps, signing in with a passkey is different from the biometric sign-in experience that has existed for many years. Signing in with a passkey requires an additional tap.

As for security, an implementation might gracefully fall back to an email OTP. The graceful fallback option that you choose should match your unique goals for security and business. So plan your UI and UX accordingly.

For service providers, you might choose a phased rollout where initially users can create passkeys only from their account settings. Then, as you gather data about the passkey sign-in experiences unique to your users' needs, you can increase the number of places where a passkey can be created, including during account creation. And you should develop a communication plan to educate users about the availability of passkeys, and their benefits. To reach users effectively, you might leverage several communication channels (in-app notifications, email, and online help resources) that align with your unique goals.

Optional patterns

For info about optional patterns, see Optional patterns.

Use cases for passkeys

Article • 09/09/2024

This topic describes some use cases for passkeys.

Use case 1: Bootstrapping

Bootstrapping an account on the web.

1.1: Authenticating the user

This section applies when the relying party (RP) doesn't yet know who is controlling the client device. There's no browser artifact available to the RP (such as a cookie or a credential ID in local storage), although for now we assume that the user has an existing account with the RP.

To bootstrap an account, serve the user a sign-in page.

Begin by asking the user for their account identifier; typically a username or email address.

To support the autofill UI for passkeys, make sure to:

1. Add the `username` and `webauthn` value to any existing autocomplete annotations on the **username** input field.

HTML

```
<div>
  <label for="username">Username:</label>
  <input name="username" id="loginform.username"
         autocomplete="username webauthn">
</div>
```

2. On page load, use an `if` statement to check to see whether autofill UI (conditional mediation) is available, then call `navigator.credentials.get()` with `mediation: "conditional"` and `userVerification: "preferred"`.

JavaScript

```
  <script>
    (async () => {
      if (
      typeof window.PublicKeyCredential !== 'undefined'
```

```
      && typeof window.PublicKeyCredential.isConditionalMediationAvailable
=== 'function'
      ) {
        const available = await
PublicKeyCredential.isConditionalMediationAvailable();

      if (available) {
          try {
            // Retrieve authentication options for
`navigator.credentials.get()`
            // from your server.
            const authOptions = await getAuthenticationOptions();
      // This call to `navigator.credentials.get()` is "set and forget."
      // The Promise will resolve only if the user successfully interacts
      // with the browser's autofill UI to select a passkey.
      const webAuthnResponse = await navigator.credentials.get({
          mediation: "conditional",
      publicKey: {
          ...authOptions,
          // See note about userVerification below.
          userVerification: "preferred",
              }
            });
      // Send the response to your server for verification, and
      // authenticate the user if the response is valid.
      await verifyAutoFillResponse(webAuthnResponse);
          } catch (err) {
          console.error('Error with conditional UI:', err);
          }
        }
      }
    })();
  </script>
```

The above will cause the following to happen:

- Retrieve the authentication options from your server. Return at least a random `challenge` and `rpId` to be associated with this authentication request.
- When the user interacts with your **username** field, the browser and platform will check whether a passkey exists (in the platform authenticator) that can be used with the relying party.
- If that *is* the case, then the passkey will be presented to the user as an option to choose (along with other credentials that can be auto-filled, such as usernames stored in the browser's password manager). The browser/platform might render a UI similar to the one shown below. Although, the exact look and feel varies from one platform or form factor to another:

- If the user selects the passkey, then the platform UI will guide the user through an (often biometrics-based) user verification check.
- If the user successfully passes the user verification, then the `navigator.credentials.get()` call succeeds and returns a WebAuthn response.
- If the user selects a credential other than a passkey, then the browser/platform chooses a different appropriate action (such as auto-filling the username), and the `navigator.credentials.get()` call doesn't resolve.
- If the user selects the "Passkey from another device" option (the exact text will vary slightly by platform), then the browser/platform will guide the user through using a FIDO2 security key or the Cross-Device Authentication (CDA) flow to use a passkey from their smartphone or tablet to deliver a WebAuthn response to the `navigator.credentials.get()` call.
- Send the WebAuthn response to your server for verification and additional security checks. If all checks succeed, then begin an authenticated session for this user.

This is why this is called the *conditional UI* (or, more commonly, the *autofill UI*) mode of WebAuthn—the platform authenticator UI that guides the user through the verification, or through using their phone, is shown only if the user has a passkey on this device (or chooses the "another device" option).

As you can see, in this mode the `navigator.credentials.get()` call either succeeds, or it doesn't because it never resolves. If it does succeed, then the result of the call will reveal both a user id and a signed WebAuthn assertion, which the relying party (RP) will use to authenticate the user.

If the call doesn't succeed, then you should perform a *legacy* user authentication. You'll obtain a username from this first page, and in subsequent pages you then serve appropriate further login challenges (such as passwords, responding to SMS challenges, etc.) to the user. Those might include *account recovery* steps in case the user has forgotten their password, or is otherwise not able to pass the regular login challenges. Once the user has passed all the login challenges, they're considered authenticated and signed in.

When the user doesn't already have an account with the relying party (RP), you'll usually give the user the option on the sign-in page to create an account. If the user chooses that option, then you'll collect the necessary information from them to open a new account. If they successfully open a new account, then they're also considered authenticated and signed-in.

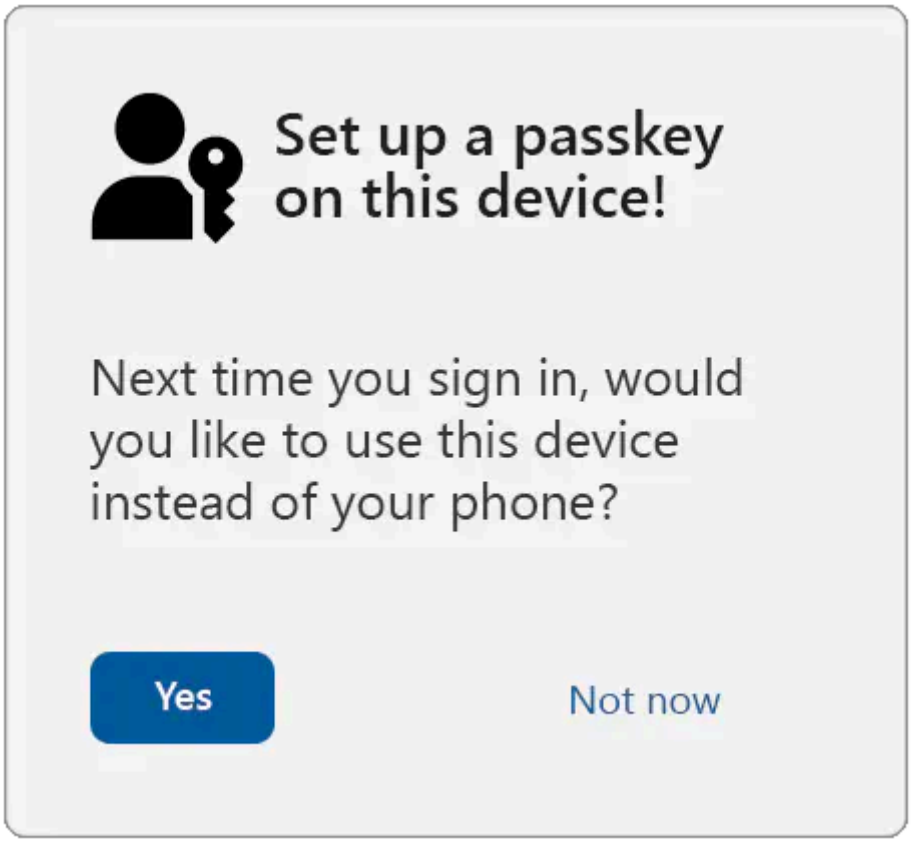
Once the user is signed in, it might be time to set up a new passkey for them. Do that for any of the following cases:

- The user bootstrapped their account on the device by passing non-passkey login challenges (such as using a password).
- The user just created a new account at the relying party (RP), and they're considered signed in because of that.
- The user was using a passkey, but they used a different device from the one they're currently using (by selecting "another device" shown in the example above). This can be confirmed by inspecting the **authenticatorAttachment** attribute in the returned **PublicKeyCredential** object.

1.2: Cross-device authentication

If the user used a passkey from another device (such as a phone, tablet, or FIDO2 security key), then the **authenticatorAttachment** property in the authentication response (**getAssertion**) will have the value `cross-platform`.

In that scenario, offer the user the choice to create a passkey on their local device. That will result in a more seamless user experience in the future, because the user won't be required to use their other device.



1.3: A note about user verification

This guidance sets **userVerification** to `preferred`, meaning that user verification will be attempted when possible.

Some devices, such as desktop computers and older laptops, might not have biometric sensors. On those devices, if **userVerification** is set to `required`, then the user might be asked to enter their system login password for each sign in using a passkey. And that can be frustrating for them.

When `preferred` is used, some platform authenticators will always require a user verification check when the device has biometric sensors, but might skip user verification on devices without them.

The user verification result (conveyed in authenticator data flags) will reflect the actual user verification result, and should always be validated against your requirements on the server.

1.4: Opt the user in to passkeys

First, verify that the user is sufficiently strongly authenticated using other login methods, including multi-factor authentication.

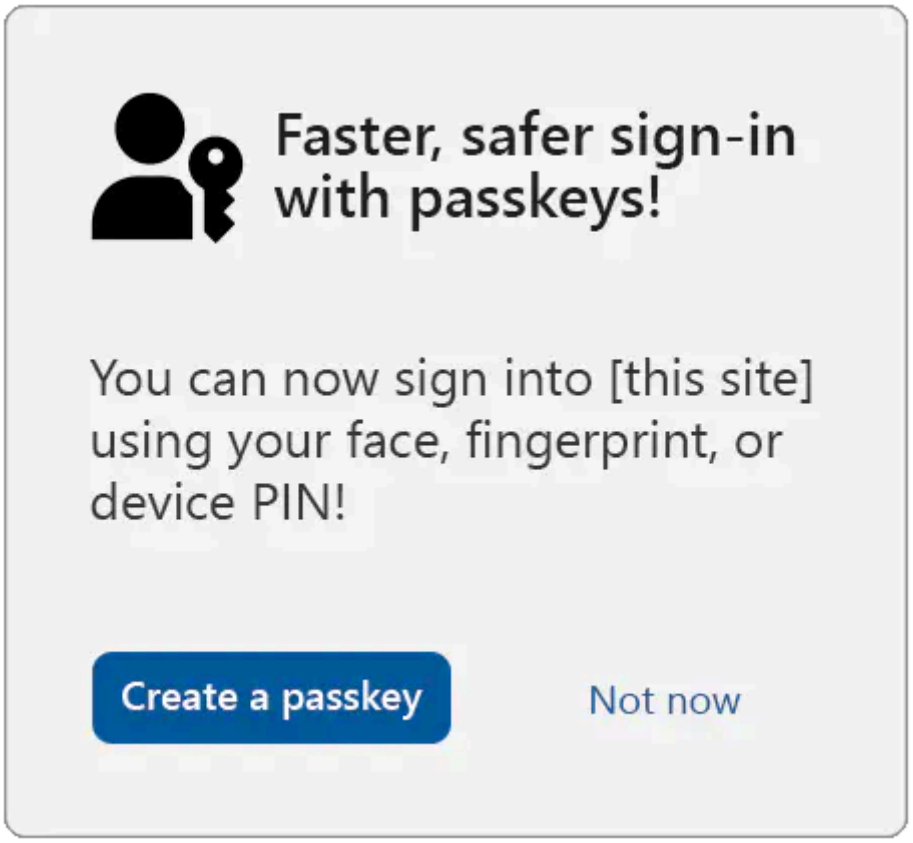
Second, ensure that the user's device and operating system (OS) combo supports passkeys by calling:

```
JavaScript

PublicKeyCredential.isUserVerifyingPlatformAuthenticatorAvailable()
```

If passkeys are supported, then that will return `true`. If they aren't supported, then it will return `false`, and you should abort the passkey enrollment flow.

Serve an opt-in or "upsell" modal/interstitial or page to the user offering them to create a passkey:



> **Tip**
>
> In order to ensure that the user is giving fully informed consent, consider showing (or linking to) longer descriptions explaining that all users who are able to unlock the current device will be able to access the account at the relying party (RP).

If the user consents, then call `navigator.credentials.create()` with the options shown in the example below:

```
JavaScript
```

```
navigator.credentials.create({
  publicKey: {
    rp: {
      // User-friendly name of your service.
      name: "Passkeys Developer",
      // Relying party (RP) identifier (hostname/FQDN).
      id: passkeys.contoso"
    },

    user: {
      // Persistent, unique identifier for the user account in your backend.
      id: Uint8Array.from("0525bc79-5a63-4e47-b7d1-597e25f5caba", c =>
c.charCodeAt(0)),
      // User-friendly identifier often displayed to the user (for example,
email address).
      name: "amanda@contoso.com",
      // Human-readable display name, sometimes displayed by the client.
      displayName: "Amanda Brady"
    },
    // The challenge is a buffer of cryptographically random bytes generated
on your backend,
    // and should be tightly bound to the current user session.
    challenge:
Uint8Array.from("XZJscsUqtBH7ZB90t2g0EbZTZYlbSRK6lq7zlN2lJKuoYMnp7Qo2OLzD7xa
wL3s", c => c.charCodeAt(0)),
    pubKeyCredParams: [
      // An array of objects describing what public key types are acceptable
to a server.
      {
        "type": "public-key",
        "alg": -7 // EC P256
      },
      {
        "type": "public-key",
        "alg": -257 // RSA
      }
    ],
    excludeCredentials: [
      // Array of credential IDs for existing passkeys tied to the user
account.
      // This avoids creating a new passkey in an authenticator that already
has
      // a passkey tied to the user account.
      {
        // Example only.
        type: "public-key",
        id: new Uint8Array([21, 31, 56, ...]).buffer
      },
      {
        // Example only.
        type: "public-key",
        id: new Uint8Array([21, 31, 56, ...]).buffer
      }
    ],
```

```
    authenticatorSelection: {
      // Tells the authenticator to create a passkey.
      residentKey: "required",
      // Tells the client/authenticator to request user verification where
possible;
      // for example, a biometric or a device PIN.
      userVerification: "preferred"
    },
    "extensions": {
      // Returns details about the passkey.
      "credProps": true
    }
  }
})
```

> ⓘ **Note**
>
> We recommend that most relying parties (RPs) not specify the attestation conveyance parameter `attestation` (thus defaulting to none), or instead explicitly use the value `indirect`. That guarantees the most streamlined user experience (platforms are likely to obtain consent from the user for other types of attestation conveyances, which likely results in a larger fraction of unsuccessful credential creations due to users canceling the creation).

When the WebAuthn call resolves, send the response to your server, and associate the returned public key and credential ID with the previously authenticated user account.

Use case 2: Reauthentication

Using passkeys for a reauthentication might be necessary for any of the following reasons:

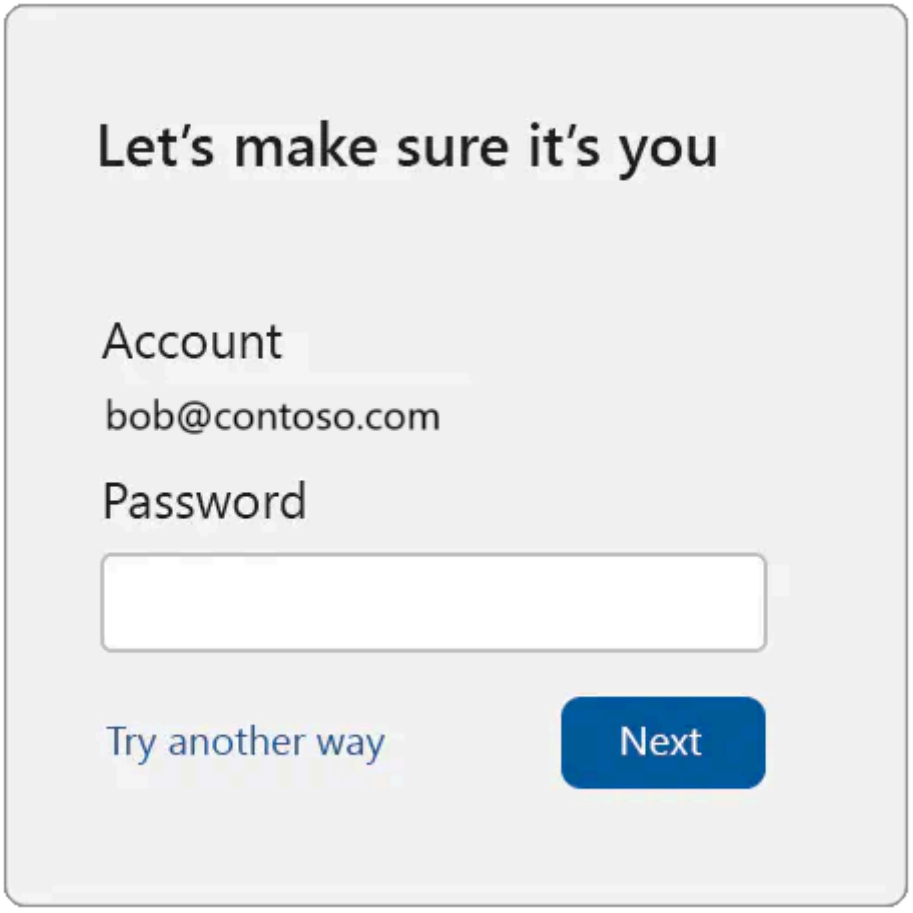
- The user signed out, and now wants to sign in again.
- The user session expired due to inactivity, and the user wants to sign in again.
- The user is about to perform a sensitive action, and needs to re-confirm control over the user session.

To reauthenticate the user in each of these situations, you'll use passkeys that you set up in the previous use case. The WebAuthn API call is the same in all three cases, but the UI treatment that you provide is slightly different. Since the particular account is specified by you, the platform won't prompt the user to select a different account on your service.

2.1: Sensitive actions

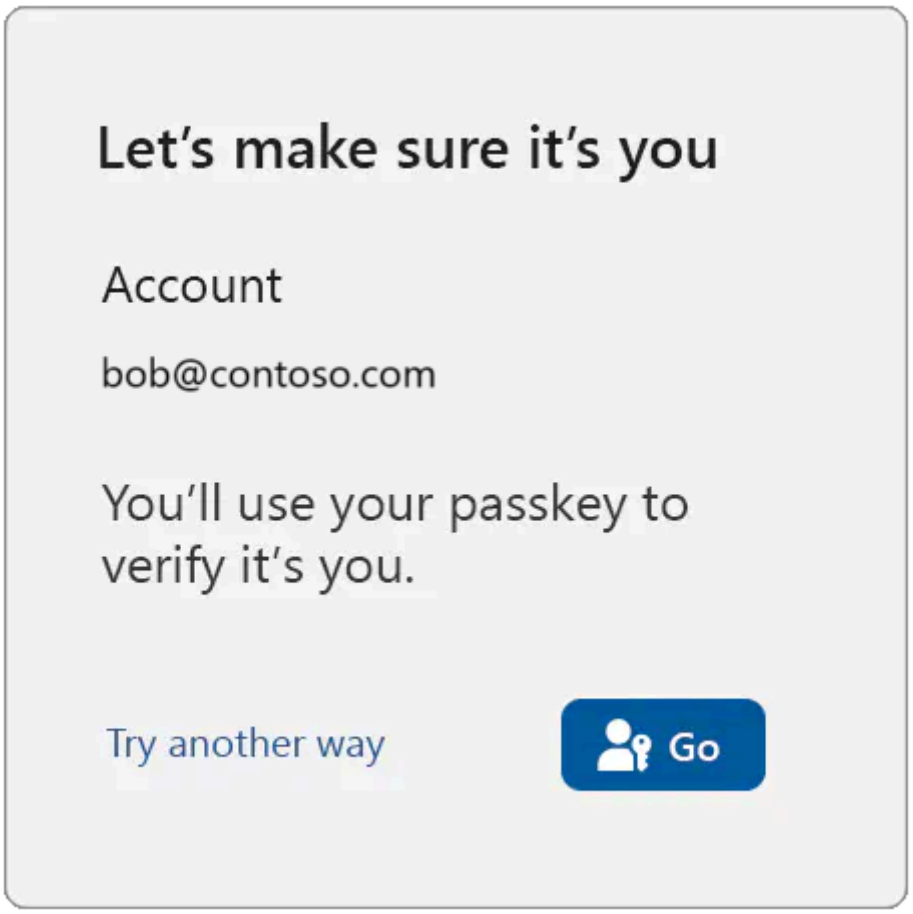
Let's look at the UI for the third reason first—when it's time to reauthenticate for a sensitive action, check whether you have a credential ID for at least one passkey for the user.

If no such credential ID is available, then serve a traditional login challenge suitable for reauthentication, for example:



> **Tip**
>
> We recommend that on this login challenge page, users can't change their account identifier. Also, the login challenge should be something that an unauthorized user of the device can't pass.

If, on the other hand, you *do* find at least one passkey credential ID for the user, then you can use passkeys for reauthentication:



When the user is ready (in the above example, when they click on the "Go" button), call `navigator.credentials.get()`, passing in all the user's passkey credential IDs:

JavaScript

```
navigator.credentials.get({
  publicKey: {
    challenge: ...,
    rpId: ...,
     allowCredentials: [{
      type: "public-key",
      id: new UInt8Array([21, 31, 56, ...]).buffer,
    }, {
      type: "public-key",
      id: new UInt8Array([21, 31, 56, ...]).buffer,
    }, {
      ...
    }],
    // see note below
    userVerification: "preferred",
  }
});
```

ⓘ Note

Be sure to read the guidance around userVerification from the previous use case.

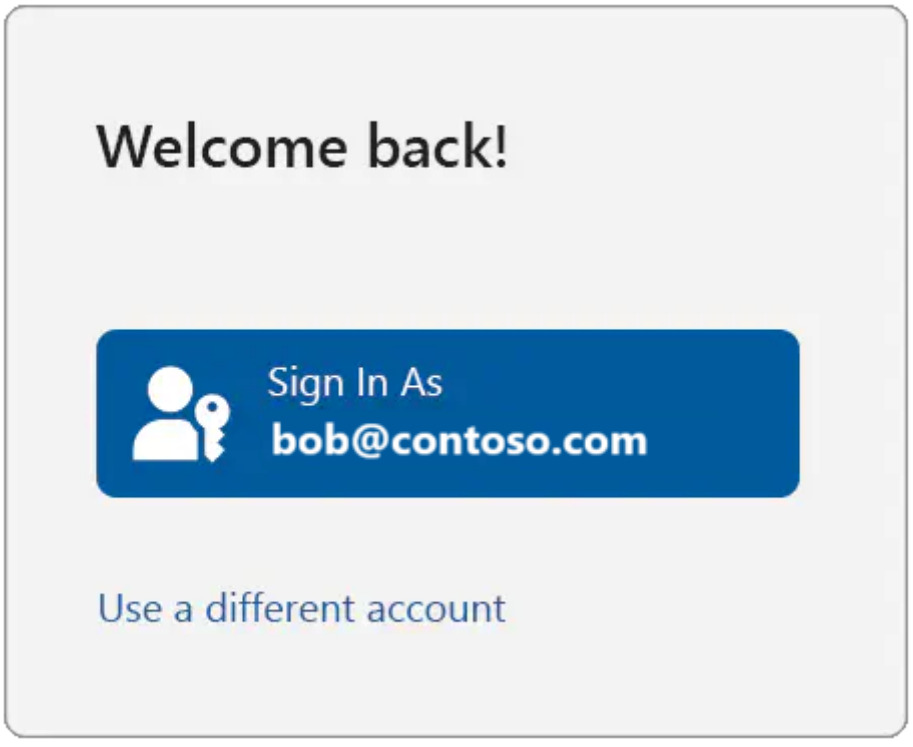
If the user instead clicks on "Try another way", then you should offer them other sign-in methods (password, etc.) to reauthenticate them (assuming that the user has such other sign-in methods available to them).

2.2: Expired sessions and logout

Now we'll examine the case where the reauthentication is triggered because the user logged themself out, or the relying party (RP) expired the user's session. To facilitate that, the RP would have to keep some form of user session state reminding them of the account that was formerly signed in, even when they consider the user signed-out (that could be achieved using browser artifacts such as cookies or local storage).

> ⓘ **Note**
>
> A relying party (RP) might choose to treat signing out as a comprehensive action, and thus delete all references to the user's identity. Such an RP should treat a subsequent sign-in like an account bootstrap, and repeat the steps explained previously.

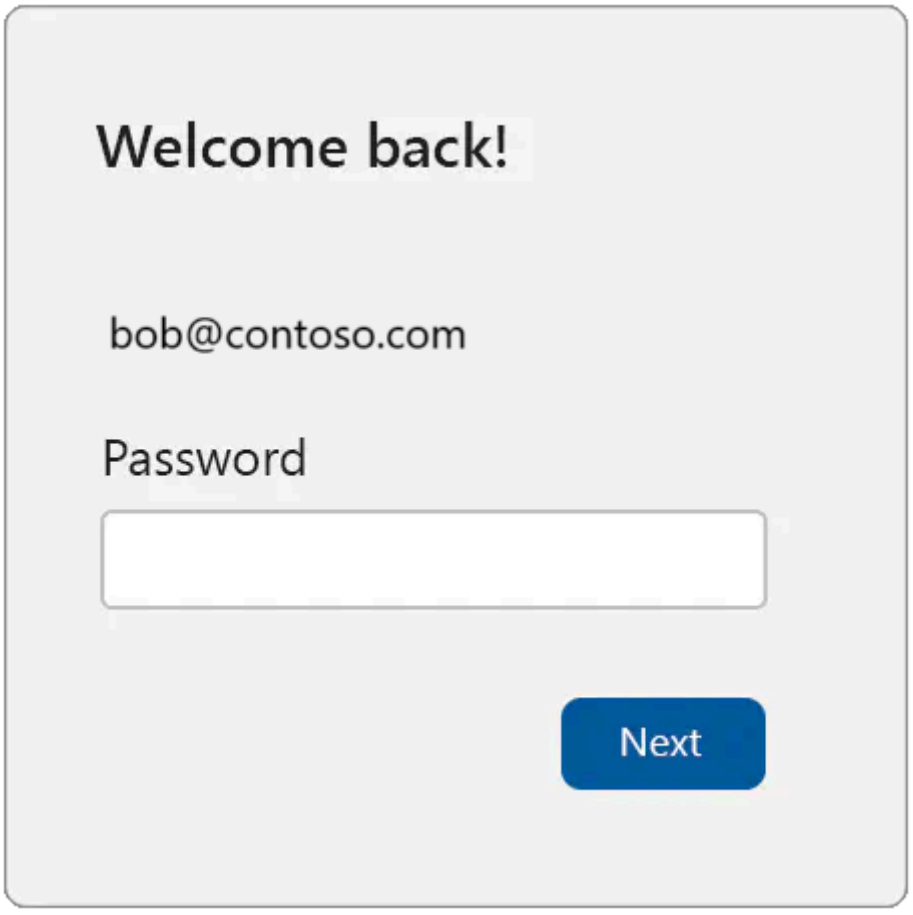
You, as the RP, might then serve a sign-in page like this:



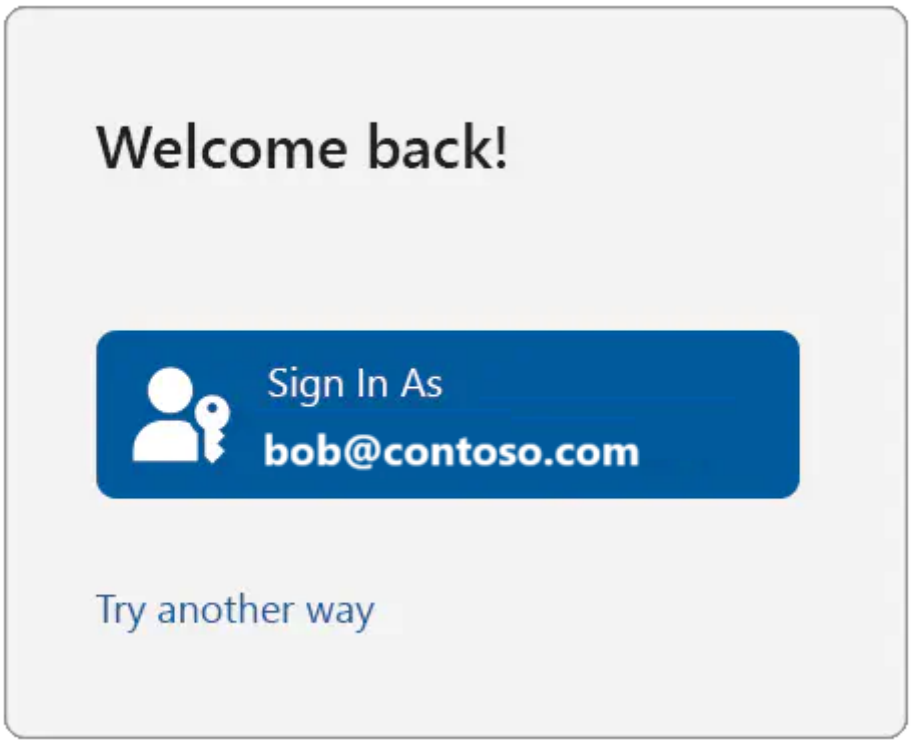
If the user clicks on "Use a different account", then you should enter an account bootstrap flow—as explained for the previous use case—repeating the steps there, where the platform will let the user select which account they want to use.

> ⓘ **Note**
>
> In that case, you should also give the user the ability to completely remove the suggested account from being listed on the sign-in page.

But if the user clicks the "Sign In As" button, then check whether you have at least one passkey credential ID associated with the user. If no credential ID is available, then serve a traditional login challenge suitable for reauthentication, for example:



If, on the other hand, you *do* find at least one passkey credential ID for the user, then you can use passkeys for reauthentication:



When the user is ready (in the above example, when they click on the "Go" button), call `navigator.credentials.get()`, exactly as already shown (that is, by passing in all the user's passkey credential IDs).

If the user instead clicks on "Try another way", then you should offer them other sign-in methods (password, etc.) to reauthenticate them (assuming that the user has such other sign-in methods available to them).

Tools and libraries for passkeys

Article • 09/09/2024

This topic contains info about tools and libraries to help you implement passkeys.

Libraries

Selection criteria

If you wish to own passwordless authentication internally, or you're looking to implement a turnkey solution for passkeys, then you'll likely be looking for libraries or vendors. When selecting a library to implement passkeys, what should you as a developer at a relying party (RP) keep an eye on?

> **Note**
>
> A small set of these criteria are not specific to passkeys, but are useful to keep in mind when selecting an open-source solution.

WebAuthn versions and capabilities

- **Version**. Check which version of the spec the library supports (Level 2, Level 3, and so on).
- **Features and capabilities**. Check whether the library includes key features and capabilities for your use case.
  - Does the library help with generating registration and authentication options? Does it help with verification of the registration and authentication response? From a relying party (RP) perspective, those are the key steps of your implementation. So make sure that the library you select provides useful functions for those steps.
  - If you're considering using attestation features:
    - Does the library help leverage FIDO MDS in some way?
    - Can the library verify all attestation statement formats?

Verification steps

Check whether the library follows the necessary verification steps:

- During registration.
- During authentication.

User interface (UI) and user experience (UX)

If you're looking for a library that offers UI elements:

- **Visual consistency**. Check that the solution uses standardized icons.
- **Clear language**. Instructions using plain language are critical for broader user understanding. Prioritize solutions aligned with the FIDO UX guidelines.

Developer experience

- **Full-stack coverage**. A library that offers tightly-integrated frontend and backend components (for example, SimpleWebAuthn) can streamline your integration.
- **Developer documentation**. In order to ease the integration process, check that the library has a maintained documentation website .

Developer involvement and maintenance

- **Open-source maintenance**. For open-source options, investigate their community activity. A few active issues, or many issues with up-to-date labels (assuming that those require manual assignment), and comments by contributors, are all signals of an active community.
- **Patience**. Standards can be slow-moving. So a WebAuthn/passkey library can go a long time between updates if there aren't any real issues with it. But that doesn't mean the library is unmaintained.

Licensing

Review the solution's licensing model (for example, MIT, Apache, commercial) in the context of your project.

Updated for passkeys

- **Rust**. Webauthn-rs - Webauthn for Rust Server Applications (William Brown).
- **TypeScript**. SimpleWebAuthn (Matthew Miller).
- **Java**. java-webauthn-server (Yubico).

Other FIDO2/WebAuthn libraries

The WebAuthn Awesome GitHub repo is also regularly updated with libraries from the community.

- **.NET**. FIDO2 .NET Library (Anders Åberg, Alex Seigler).
- **Go**. WebAuthn Library.
- **Java**. WebAuthn4J (Yoshikazu Nojima).
- **Python**. py_webauthn (Duo Labs).
- **Ruby**. webauthn-ruby (Cedarcode), Devise::Passkeys (Ruby Passkeys, wrapper around webauthn-ruby), and Warden::WebAuthn (Ruby Passkeys, wrapper around webauthn-ruby).

Test sites and tools

In addition to the resources listed in the sections below, the WebAuthn Awesome GitHub repo is also regularly updated with tools and demos from the community.

Basic FIDO2/WebAuthn tools

- WebAuthn.io.
- yubico demo site.
- webauthn.

Advanced FIDO2/WebAuthn tools

- lbuchs/WebAuthn.
- WebAuthn Debugger.
- WebAuthn Developer Tool.

Reference for passkeys on Windows

Article • 02/19/2025

This topic offers some reference info, demos, and examples for passkeys on Windows.

Overview

Passkeys can be used in all supported versions of Windows clients. As of the September 2023 moment, for Windows 11, version 22H2 with KB5030310 or later, native support for passkey management is available (see Support for passkeys in Windows). Windows native credential UX is displayed when a user saves or signs in with a passkey (even from the browser). Users can perform passkey management from Windows settings or Edge. Cross-device authentication through the browser, leveraging chromium-based credential UI, is still available.

Cross-Device authentication

Starting in Windows 11, version 23H2, FIDO Cross-Device Authentication (CDA) is supported globally at the operating system (OS) level, and is available for all apps and browsers. Persistent linking is available between Android devices (authenticator) and Windows 11, version 23H2, and later. iOS and iPadOS don't support persistent linking.

User-verification behavior

When a user tries to interact with a passkey on Windows 11, an available screen unlock method is used for user verification via Windows Hello. Setting up facial recognition or fingerprint recognition are optional.

Where those biometrics are not configured or available, both passkey creation and authentication fall back to requesting the Windows Hello PIN.

Demos and examples

See Windows Reference on passkeys.dev and Demo Sites.

Third-party passkey manager support

Article • 12/12/2024

This topic describes the third-party credential manager API plugin support for third-party passkey providers on Windows. It showcases a demo app named Contoso Passkey Manager.

Contoso Passkey Manager

Windows 11 supports a third-party plugin model for passkeys. Contoso Passkey Manager is a demo app that demonstrates this passkey provider support.

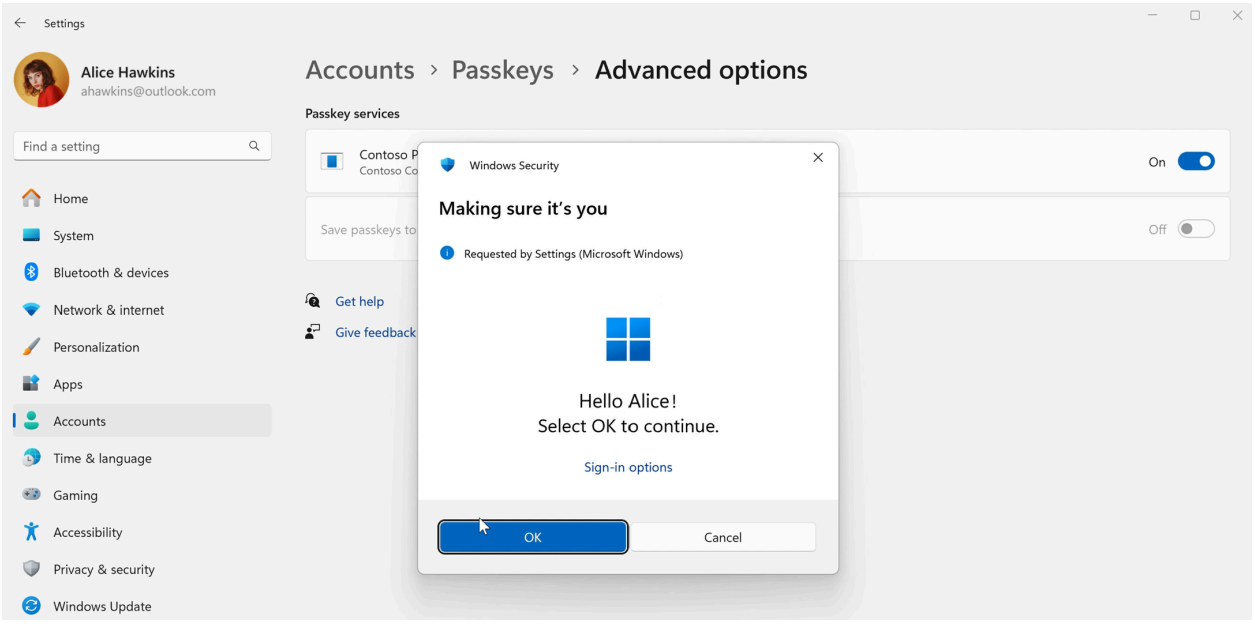
> ⚠ **Warning**
>
> Contoso Passkey Manager is designed for passkey creation and usage testing only. Don't use the app for production passkeys.

Step 1: Installation

1. Set up your development environment for WinUI 3 development (see Install tools for the Windows App SDK).
2. Clone the Windows-classic-samples GitHub repo for the Contoso Passkey Manager sample app.
3. In Visual Studio, open the Contoso Passkey Manager solution that you just cloned, carefully follow the instructions at the link above, build the sample, and then run it to confirm installation.

Step 2: Setup

1. Go to **Settings** > **Accounts** > **Passkeys**, and then **Advanced options**.
2. Switch the toggle to **On** for Contoso Passkey Manager.
3. Complete the Windows Hello user verification, and now you can save passkeys to the Contoso Passkey Manager.

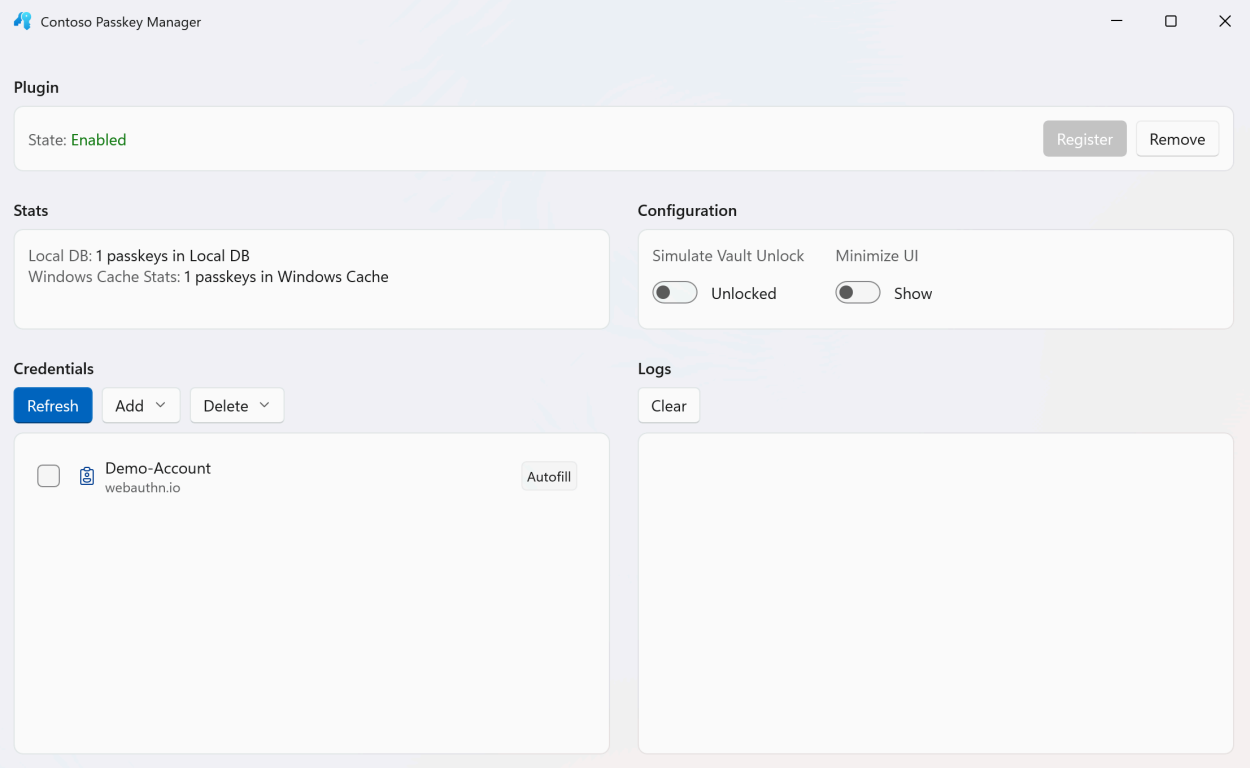


Step 3: Passkey creation

1. Navigate to a website such as webauthn.io.
2. Create a test user name, and click **Register**.
3. You will be prompted, on saving your passkey, with the Contoso Passkey Manager. Click **Continue**.

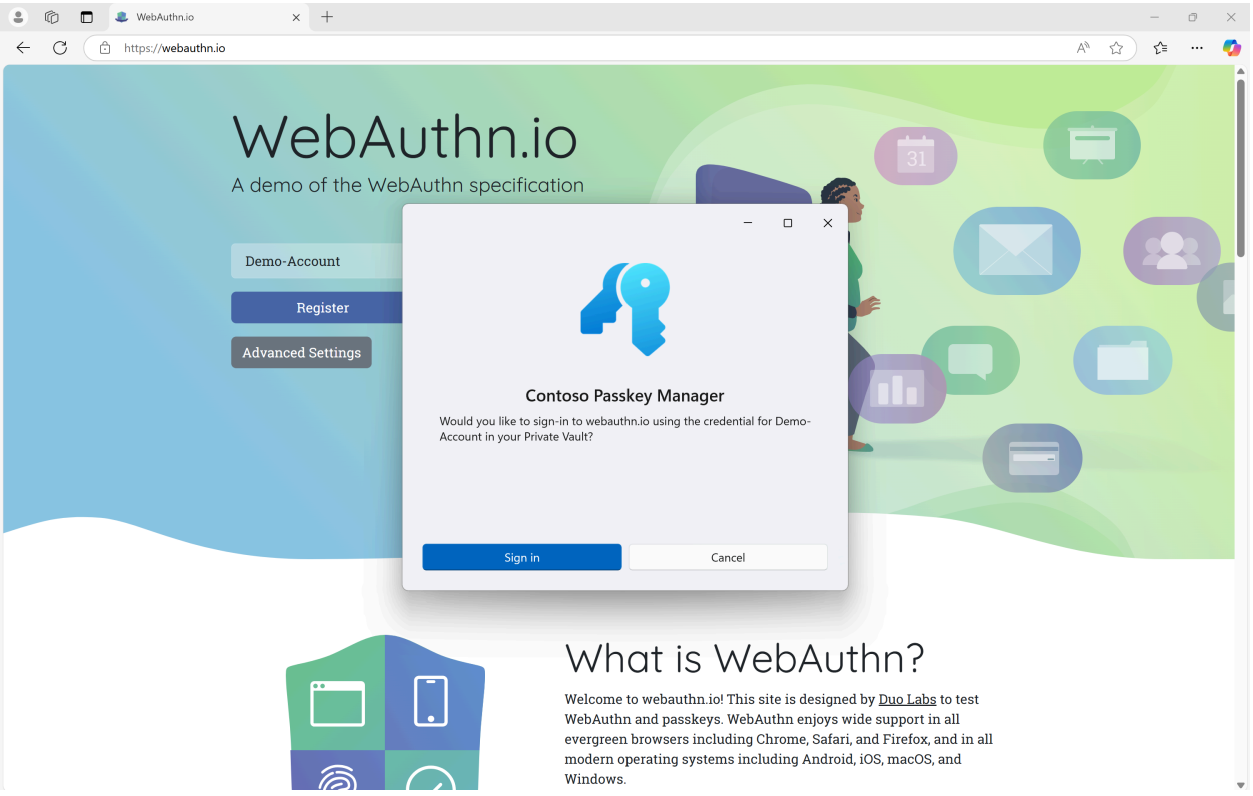
4. The Contoso Passkey Manager app will open. Click **Create** to create the credential in Contoso Passkey Manager.
5. Complete user verification with Windows Hello, and the passkey is created.
6. You can see your saved passkeys by opening the Contoso Passkey Manager.
7. If you want to test different experiences, then you can toggle **Simulate Vault Unlock** to test a vault unlock user experience when saving a passkey. The **Minimize**

UI toggle simplifies the step that opens the passkey manager, and the experience flow will instead just be with user verification on Windows Hello.



Step 4: Passkey authentication

1. Input your username, and click **Authenticate**.
2. Select to sign in with the passkey saved to the Contoso Passkey Manager.



3. Complete user verification with Windows Hello to authenticate.

4. You've successfully logged in.

Next steps

To integrate with the third-party plugin capability, go to webauthn to find the header files.

Implement OAuth 2.0 functionality in Windows apps

Article • 03/19/2025

The OAuth2Manager in Windows App SDK enables desktop applications such as WinUI 3 to seamlessly perform OAuth 2.0 authorization on Windows. **OAuth2Manager** API intentionally doesn't provide APIs for the implicit request and resource owner password credential because of the security concerns that entails. It's recommended to use the authorization code grant type using Proof Key for Code Exchange (PKCE). For more information, see the PKCE RFC.

OAuth background

The Windows Runtime (WinRT) WebAuthenticationBroker, primarily designed for UWP apps, presents several challenges when used in desktop apps. Key issues include the dependency on ApplicationView, which isn't compatible with desktop app frameworks. As a result, developers are forced to resort to workarounds involving interop interfaces and additional code to implement OAuth 2.0 functionality into WinUI 3 and other desktop apps.

OAuth2Manager API in Windows App SDK

The **OAuth2Manager** API for Windows App SDK aims to provide a streamlined solution that meets the expectations of developers. It offers seamless OAuth 2.0 capabilities with full feature parity across all Windows platforms supported by Windows App SDK. The new API eliminates the need for cumbersome workarounds and simplifies the process of incorporating OAuth 2.0 functionality into desktop apps.

The **OAuth2Manager** is different than the **WebAuthenticationBroker** in WinRT. It follows OAuth 2.0 best practices more closely - e.g. using the user's default browser. The best practices for the API are taken from the IETF (Internet Engineering Task Force) OAuth 2.0 Authorization Framework RFC 6749, PKCE RFC 7636, and OAuth 2.0 for Native Apps RFC 8252.

Perform OAuth 2.0 examples

A full WinUI 3 sample app is available on GitHub. The following sections provide code snippets for the most common OAuth 2.0 flows using the **OAuth2Manager** API.

Authorization code request

The following example demonstrates how to perform an authorization code request using the **OAuth2Manager** in Windows App SDK:

C++

```
// Get the WindowId for the application window
Microsoft::UI::WindowId parentWindowId = this->AppWindow().Id();

AuthRequestParams authRequestParams =
AuthRequestParams::CreateForAuthorizationCodeRequest(L"my_client_id",
   Uri(L"my-app:/oauth-callback/"));
authRequestParams.Scope(L"user:email user:birthday");

AuthRequestResult authRequestResult = co_await
OAuth2Manager::RequestAuthWithParamsAsync(parentWindowId,
   Uri(L"https://my.server.com/oauth/authorize"), authRequestParams);
if (AuthResponse authResponse = authRequestResult.Response())
{
   //To obtain the authorization code
   //authResponse.Code();

   //To obtain the access token
   DoTokenExchange(authResponse);
}
else
{
   AuthFailure authFailure = authRequestResult.Failure();
   NotifyFailure(authFailure.Error(), authFailure.ErrorDescription());
}
```

Exchange authorization code for access token

The following example demonstrates how to exchange an authorization code for an access token using the **OAuth2Manager**:

C++

```
AuthResponse authResponse = authRequestResult.Response();
TokenRequestParams tokenRequestParams =
TokenRequestParams::CreateForAuthorizationCodeRequest(authResponse);
ClientAuthentication clientAuth =
ClientAuthentication::CreateForBasicAuthorization(L"my_client_id",
    L"my_client_secret");
```

```
TokenRequestResult tokenRequestResult = co_await
OAuth2Manager::RequestTokenAsync(
    Uri(L"https://my.server.com/oauth/token"), tokenRequestParams,
clientAuth);
if (TokenResponse tokenResponse = tokenRequestResult.Response())
{
    String accessToken = tokenResponse.AccessToken();
    String tokenType = tokenResponse.TokenType();

    // RefreshToken string null/empty when not present
    if (String refreshToken = tokenResponse.RefreshToken();
!refreshToken.empty())
    {
        // ExpiresIn is zero when not present
        DateTime expires = winrt::clock::now();
        if (String expiresIn = tokenResponse.ExpiresIn();
std::stoi(expiresIn) != 0)
        {
            expires += std::chrono::seconds(static_cast<int64_t>
(std::stoi(expiresIn)));
        }
        else
        {
            // Assume a duration of one hour
            expires += std::chrono::hours(1);
        }

        //Schedule a refresh of the access token
        myAppState.ScheduleRefreshAt(expires, refreshToken);
    }

    // Use the access token for resources
    DoRequestWithToken(accessToken, tokenType);
}
else
{
    TokenFailure tokenFailure = tokenRequestResult.Failure();
    NotifyFailure(tokenFailure.Error(),
tokenFailure.ErrorDescription());
}
```

Refresh an access token

The following example shows how to refresh an access token using the **OAuth2Manager**'s RefreshTokenAsync method:

C++

```
TokenRequestParams tokenRequestParams =
TokenRequestParams::CreateForRefreshToken(refreshToken);
ClientAuthentication clientAuth =
ClientAuthentication::CreateForBasicAuthorization(L"my_client_id",
    L"my_client_secret");
TokenRequestResult tokenRequestResult = co_await
OAuth2Manager::RequestTokenAsync(
    Uri(L"https://my.server.com/oauth/token"), tokenRequestParams,
clientAuth));
if (TokenResponse tokenResponse = tokenRequestResult.Response())
{
    UpdateToken(tokenResponse.AccessToken(), tokenResponse.TokenType(),
tokenResponse.ExpiresIn());

    //Store new refresh token if present
    if (String refreshToken = tokenResponse.RefreshToken();
!refreshToken.empty())
    {
        // ExpiresIn is zero when not present
        DateTime expires = winrt::clock::now();
        if (String expiresInStr = tokenResponse.ExpiresIn();
!expiresInStr.empty())
        {
            int expiresIn = std::stoi(expiresInStr);
            if (expiresIn != 0)
            {
                expires += std::chrono::seconds(static_cast<int64_t>
(expiresIn));
            }
        }
        else
        {
            // Assume a duration of one hour
            expires += std::chrono::hours(1);
        }

        //Schedule a refresh of the access token
        myAppState.ScheduleRefreshAt(expires, refreshToken);
    }
}
else
{
    TokenFailure tokenFailure = tokenRequestResult.Failure();
    NotifyFailure(tokenFailure.Error(),
tokenFailure.ErrorDescription());
}
```

Complete an authorization request

Finally, to complete an authorization request from a protocol activation, your app should handle the AppInstance.Activated event. This is required when having custom redirect logic. A full example is available on GitHub.

Use the following code:

C++

```
void App::OnActivated(const IActivatedEventArgs& args)
{
    if (args.Kind() == ActivationKind::Protocol)
    {
        auto protocolArgs = args.as<ProtocolActivatedEventArgs>();
        if (OAuth2Manager::CompleteAuthRequest(protocolArgs.Uri()))
        {
            TerminateCurrentProcess();
        }

        DisplayUnhandledMessageToUser();
    }
}
```

Share certificates between Windows apps

Article • 11/22/2024

Windows apps that require secure authentication beyond a user Id and password combination can use certificates for authentication. Certificate authentication provides a high level of trust when authenticating a user. In some cases, a group of services will want to authenticate a user for multiple apps. This article shows how you can authenticate multiple Windows apps using the same certificate, and how you can provide a method for users to import a certificate that was provided for access to secured web services.

Apps can authenticate to a web service using a certificate, and multiple apps can use a single certificate from the certificate store to authenticate the same user. If a certificate does not exist in the store, you can add code to your app to import a certificate from a PFX file. The client app in this quickstart is a WinUI app, and the web service is an ASP.NET Core web API.

> **Tip**
>
> Microsoft Copilot is a great resource if you have questions about getting started writing Windows apps or ASP.NET Core web APIs. Copilot can help you write code, find examples, and learn more about best practices for creating secure apps.

Prerequisites

- Visual Studio with the **ASP.NET and web development** and **Windows application development** workloads installed.
- The latest Windows Software Development Kit (SDK) to use the Windows Runtime (WinRT) APIs in your WinUI app.
- PowerShell for working with self-signed certificates.

Create and publish a secured web service

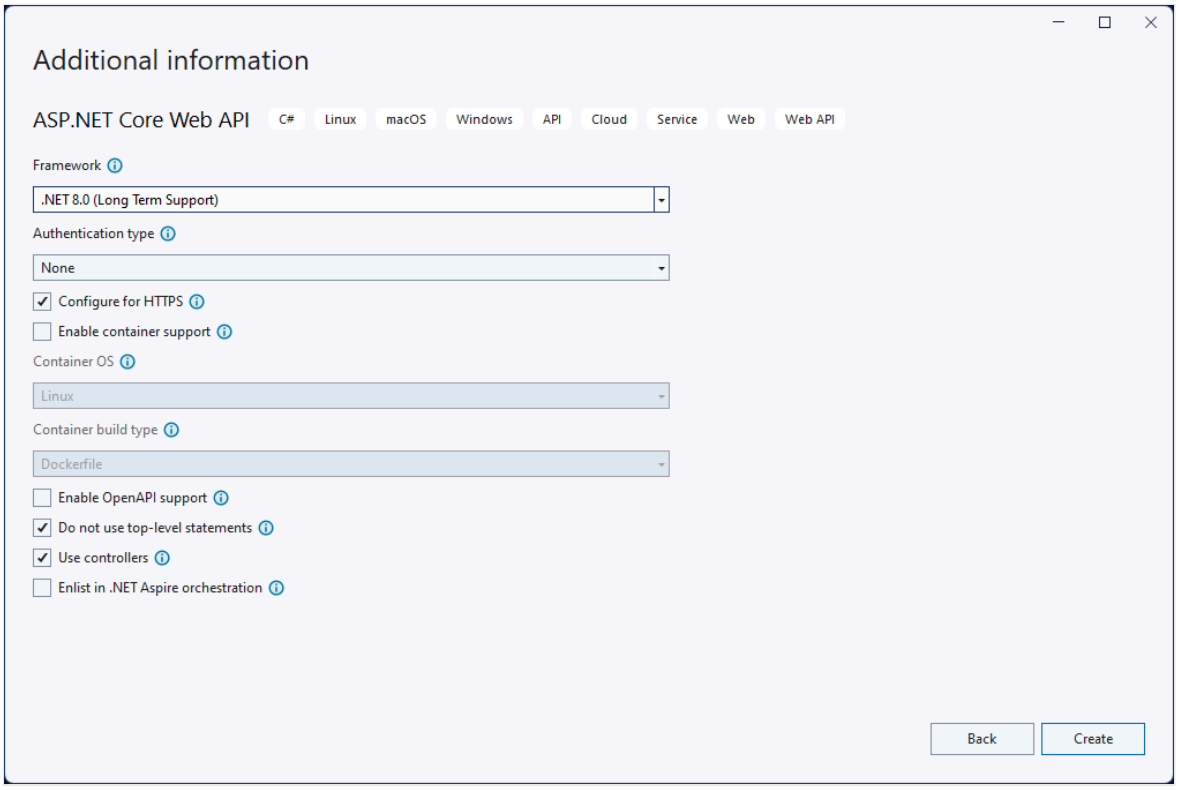
1. Open Microsoft Visual Studio and select **Create a new project** from the start screen.

2. In the Create a new project dialog, select **API** in the **Select a project type** dropdown list to filter the available project templates.

3. Select the **ASP.NET Core Web API** template and select **Next**.

4. Name the application "FirstContosoBank" and select **Next**.

5. Choose **.NET 8.0** or later as the **Framework**, set the **Authentication type** to **None**, ensure **Configure for HTTPS** is checked, uncheck **Enable OpenAPI support**, check **Do not use top-level statements** and **Use controllers**, and select **Create**.



6. Right-click the **WeatherForecastController.cs** file in the **Controllers** folder and select **Rename**. Change the name to **BankController.cs** and let Visual Studio rename the class and all references to the class.

7. In the **launchSettings.json** file, change the value of "launchUrl" from "weatherforecast" to "bank" for all three configuration what use the value.

8. In the **BankController.cs** file, add following "Login" method.

cs

```cs
[HttpGet]
[Route("login")]
public string Login()
{
    // Return any value you like here.
    // The client is just looking for a 200 OK response.
```

```
    return "true";
}
```

9. Open the NuGet Package Manager and search for and install latest stable version of the **Microsoft.AspNetCore.Authentication.Certificate** package. This package provides middleware for certificate authentication in ASP.NET Core.

10. Add a new class to the project named **SecureCertificateValidationService**. Add the following code to the class to configure the certificate authentication middleware.

cs

```
using System.Security.Cryptography.X509Certificates;

public class SecureCertificateValidationService
{
    public bool ValidateCertificate(X509Certificate2 clientCertificate)
    {
        // Values are hard-coded for this example.
        // You should load your valid thumbprints from a secure
location.
        string[] allowedThumbprints = {
"YOUR_CERTIFICATE_THUMBPRINT_1", "YOUR_CERTIFICATE_THUMBPRINT_2" };
        if (allowedThumbprints.Contains(clientCertificate.Thumbprint))
        {
            return true;
        }
    }
}
```

11. Open **Program.cs** and replace the code in the **Main** method with the following code:

C#

```
public static void Main(string[] args)
{
    var builder = WebApplication.CreateBuilder(args);

    // Add our certificate validation service to the DI container.
    builder.Services.AddTransient<SecureCertificateValidationService>
();

    builder.Services.Configure<KestrelServerOptions>(options =>
    {
        // Configure Kestrel to require a client certificate.
        options.ConfigureHttpsDefaults(options =>
        {
            options.ClientCertificateMode =
ClientCertificateMode.RequireCertificate;
```

```
            options.AllowAnyClientCertificate();
        });
    });

    builder.Services.AddControllers();

    // Add certificate authentication middleware.
    builder.Services.AddAuthentication(
    CertificateAuthenticationDefaults.AuthenticationScheme)
       .AddCertificate(options =>
    {
        options.AllowedCertificateTypes = CertificateTypes.SelfSigned;
        options.Events = new CertificateAuthenticationEvents
        {
            // Validate the certificate with the validation service.
            OnCertificateValidated = context =>
            {
                var validationService =
context.HttpContext.RequestServices.GetService<SecureCertificateValidat
ionService>();

                if
(validationService.ValidateCertificate(context.ClientCertificate))
                {
                    context.Success();
                }
                else
                {
                    context.Fail("Invalid certificate");
                }

                return Task.CompletedTask;
            },
            OnAuthenticationFailed = context =>
            {
                context.Fail("Invalid certificate");
                return Task.CompletedTask;
            }
        };
     });

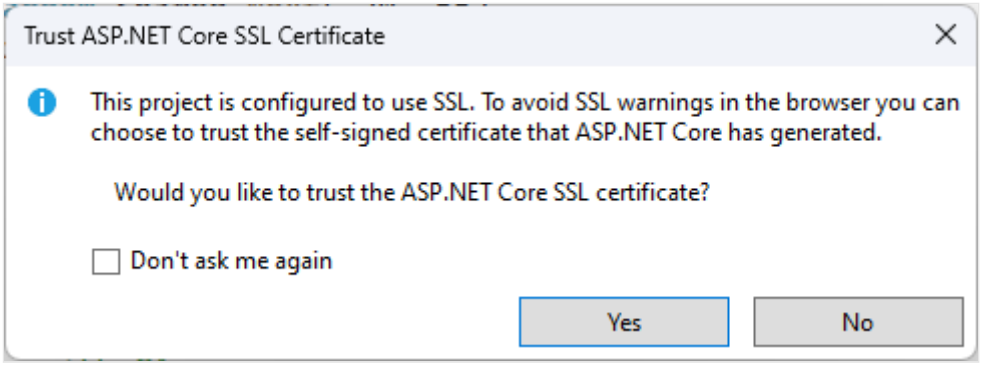
     var app = builder.Build();

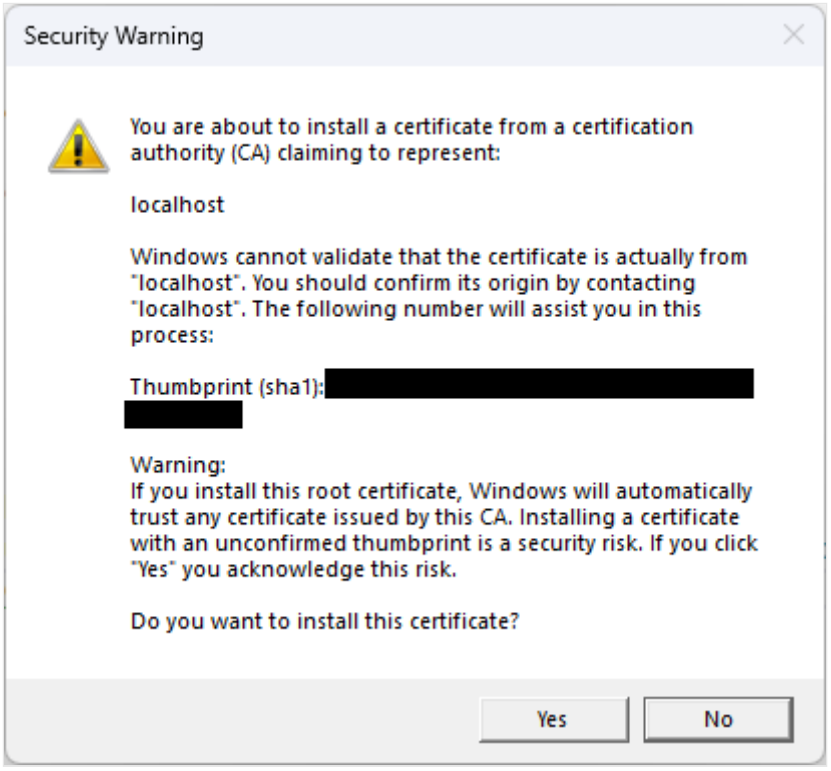
     // Add authentication/authorization middleware.
     app.UseHttpsRedirection();
     app.UseAuthentication();
     app.UseAuthorization();

     app.MapControllers();
     app.Run();
 }
```

The code above configures the Kestrel server to require a client certificate and adds the certificate authentication middleware to the app. The middleware validates the client certificate using the `SecureCertificateValidationService` class. The `OnCertificateValidated` event is called when a certificate is validated. If the certificate is valid, the event calls the `Success` method. If the certificate is invalid, the event calls the `Fail` method with an error message, which will be returned to the client.

12. Start debugging the project to launch the web service. You may receive messages about trusting and installing an SSL certificate. Click **Yes** for each of these messages to trust the certificate and continue debugging the project.





13. The web service will be available at `https://localhost:7072/bank`. You can test the web service by opening a web browser and entering the web address. You will see the generated weather forecast data formatted as JSON. Keep the web service running while you create the client app.

For more information on working with ASP.NET Core controller-based web APIs, see Create a web API with ASP.NET Core.

Create a WinUI app that uses certificate authentication

Now that you have one or more secured web services, your apps can use certificates to authenticate to those web services. When you make a request to an authenticated web service using the HttpClient object from the WinRT APIs, the initial request will not contain a client certificate. The authenticated web service will respond with a request for client authentication. When this occurs, the Windows client will automatically query the certificate store for available client certificates. Your user can select from these certificates to authenticate to the web service. Some certificates are password protected, so you will need to provide the user with a way to input the password for a certificate.

> **Note**
>
> There are no Windows App SDK APIs for managing certificates yet. You must use the WinRT APIs to manage certificates in your app. We will also be using WinRT storage APIs to import a certificate from a PFX file. Many WinRT APIs can be used by any Windows app with package identity, including WinUI apps.
>
> The HTTP client code we'll implement uses .NET's HttpClient. The HttpClient included in the WinRT APIs doesn't support client certificates.

If there are no client certificates available, then the user will need to add a certificate to the certificate store. You can include code in your app that enables a user to select a PFX file that contains a client certificate and then import that certificate into the client certificate store.

> **Tip**
>
> You can use the PowerShell cmdlets **New-SelfSignedCertificate** and **Export-PfxCertificate** to create a self-signed certificate and export it to a PFX file to use with this quickstart. For information, see New-SelfSignedCertificate and Export-PfxCertificate.
>
> Note that when generating the certificate, you should save the thumbprint of the certificate to use in the web service for validation.

1. Open Visual Studio and create a new WinUI project from the start page. Name the new project "FirstContosoBankApp". Click **Create** to create the new project.

2. In the **MainWindow.xaml** file, add the following XAML to a **Grid** element, replacing the existing **StackPanel** element and its contents. This XAML includes a button to browse for a PFX file to import, a text box to enter a password for a password-protected PFX file, a button to import a selected PFX file, a button to log in to the secured web service, and a text block to display the status of the current action.

```xml
<Button x:Name="Import" Content="Import Certificate (PFX file)"
HorizontalAlignment="Left" Margin="352,305,0,0" VerticalAlignment="Top"
Height="77" Width="260" Click="Import_Click" FontSize="16"/>
<Button x:Name="Login" Content="Login" HorizontalAlignment="Left"
Margin="611,305,0,0" VerticalAlignment="Top" Height="75" Width="240"
Click="Login_Click" FontSize="16"/>
<TextBlock x:Name="Result" HorizontalAlignment="Left"
Margin="355,398,0,0" TextWrapping="Wrap" VerticalAlignment="Top"
Height="153" Width="560"/>
<PasswordBox x:Name="PfxPassword" HorizontalAlignment="Left"
Margin="483,271,0,0" VerticalAlignment="Top" Width="229"/>
<TextBlock HorizontalAlignment="Left" Margin="355,271,0,0"
TextWrapping="Wrap" Text="PFX password" VerticalAlignment="Top"
FontSize="18" Height="32" Width="123"/>
<Button x:Name="Browse" Content="Browse for PFX file"
HorizontalAlignment="Left" Margin="352,189,0,0" VerticalAlignment="Top"
Click="Browse_Click" Width="499" Height="68" FontSize="16"/>
<TextBlock HorizontalAlignment="Left" Margin="717,271,0,0"
TextWrapping="Wrap" Text="(Optional)" VerticalAlignment="Top"
Height="32" Width="83" FontSize="16"/>
```

3. Save the **MainWindow** changes.

4. Open the **MainWindow.xaml.cs** file, and add the following `using` statements.

```cs
using System;
using System.Security.Cryptography.X509Certificates;
using System.Diagnostics;
using System.Net.Http;
using System.Net;
using System.Text;
using Microsoft.UI.Xaml;
using Windows.Security.Cryptography.Certificates;
using Windows.Storage.Pickers;
using Windows.Storage;
using Windows.Storage.Streams;
```

5. In the MainWindow.xaml.cs file, add the following variables to the **MainWindow** class. They specify the address for the secured **login** service endpoint of your "FirstContosoBank" web service, and a global variable that holds a PFX certificate to import into the certificate store. Update the `<server-name>` to `localhost:7072` or whichever port is specified in the "https" configuration in your API project's launchSettings.json file.

```cs
private Uri requestUri = new Uri("https://<server-name>/bank/login");
private string pfxCert = null;
```

6. In the **MainWindow.xaml.cs** file, add the following click handler for the login button and method to access the secured web service.

```cs
private void Login_Click(object sender, RoutedEventArgs e)
{
    MakeHttpsCall();
}

private async void MakeHttpsCall()
{
    var result = new StringBuilder("Login ");

    // Load the certificate
    var certificate = new
X509Certificate2(Convert.FromBase64String(pfxCert),
                                            PfxPassword.Password);

    // Create HttpClientHandler and add the certificate
    var handler = new HttpClientHandler();
    handler.ClientCertificates.Add(certificate);
    handler.ClientCertificateOptions =
ClientCertificateOption.Automatic;

    // Create HttpClient with the handler
    var client = new HttpClient(handler);

    try
    {
        // Make a request
        var response = await client.GetAsync(requestUri);

        if (response.StatusCode == HttpStatusCode.OK)
        {
            result.Append("successful");
        }
        else
```

```
        {
            result = result.Append("failed with ");
            result = result.Append(response.StatusCode);
        }
    }
    catch (Exception ex)
    {
        result = result.Append("failed with ");
        result = result.Append(ex.Message);
    }

    Result.Text = result.ToString();
}
```

7. Next, add the following click handlers for the button to browse for a PFX file and the button to import a selected PFX file into the certificate store.

cs

```
private async void Import_Click(object sender, RoutedEventArgs e)
{
    try
    {
        Result.Text = "Importing selected certificate into user
certificate store....";
        await
CertificateEnrollmentManager.UserCertificateEnrollmentManager.ImportPfx
DataAsync(
              pfxCert,
              PfxPassword.Password,
              ExportOption.Exportable,
              KeyProtectionLevel.NoConsent,
              InstallOptions.DeleteExpired,
              "Import Pfx");

        Result.Text = "Certificate import succeeded";
    }
    catch (Exception ex)
    {
        Result.Text = "Certificate import failed with " + ex.Message;
    }
}

private async void Browse_Click(object sender, RoutedEventArgs e)
{
    var result = new StringBuilder("Pfx file selection ");
    var pfxFilePicker = new FileOpenPicker();
    IntPtr hwnd = WinRT.Interop.WindowNative.GetWindowHandle(this);
    WinRT.Interop.InitializeWithWindow.Initialize(pfxFilePicker, hwnd);
    pfxFilePicker.FileTypeFilter.Add(".pfx");
    pfxFilePicker.CommitButtonText = "Open";
    try
    {
```

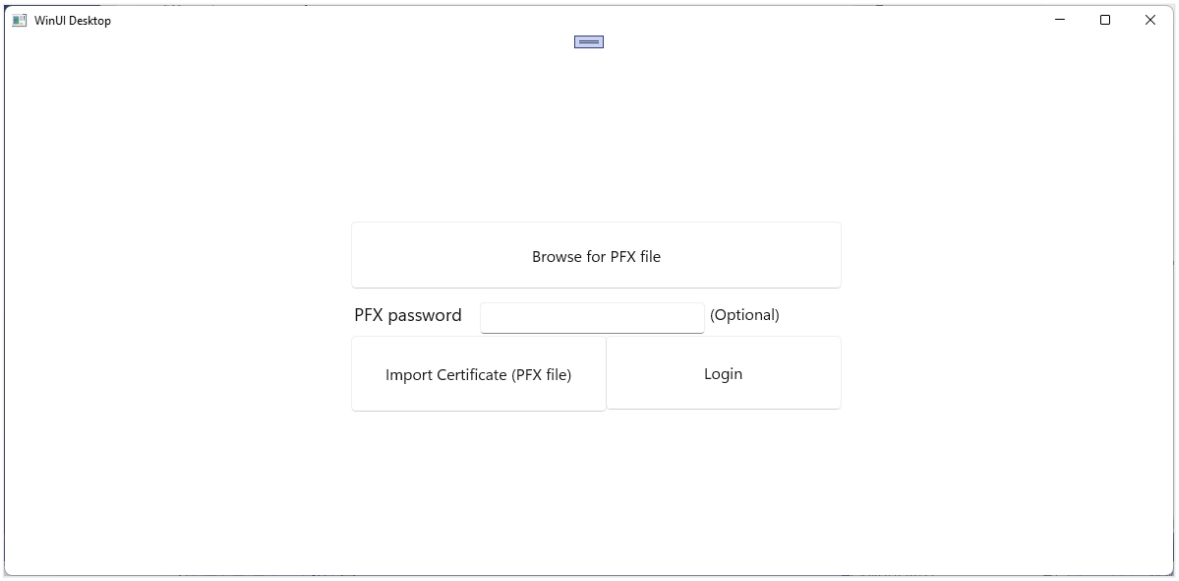
```
        StorageFile pfxFile = await
pfxFilePicker.PickSingleFileAsync();
        if (pfxFile != null)
        {
            IBuffer buffer = await FileIO.ReadBufferAsync(pfxFile);
            using (DataReader dataReader =
DataReader.FromBuffer(buffer))
            {
                byte[] bytes = new byte[buffer.Length];
                dataReader.ReadBytes(bytes);
                pfxCert = System.Convert.ToBase64String(bytes);
                PfxPassword.Password = string.Empty;
                result.Append("succeeded");
            }
        }
        else
        {
            result.Append("failed");
        }
    }
    catch (Exception ex)
    {
        result.Append("failed with ");
        result.Append(ex.Message); ;
    }

    Result.Text = result.ToString();
}
```

8. Open the **Package.appxmanifest** file and add the following capabilities to the **Capabilities** tab.

    - **EnterpriseAuthentication**
    - **SharedUserCertificates**

9. Run your app and log in to your secured web service as well as import a PFX file into the local certificate store.



You can use these steps to create multiple apps that use the same user certificate to access the same or different secured web services.

Create a web API with ASP.NET Core

Smart cards

Article • 08/09/2024

This topic explains how Windows apps can use smart cards to connect users to secure network services, including how to access physical smart card readers, create virtual smart cards, communicate with smart cards, authenticate users, reset user PINs, and remove or disconnect smart cards.

The Windows Runtime (WinRT) APIs for smart cards are part of the Windows Software Development Kit (SDK). These APIs were created for use in Universal Windows Platform (UWP) apps, but they can also be used in WinUI apps or in packaged desktop apps, including WPF and Windows Forms. For more information about using WinRT APIs in your Windows desktop app, see Call Windows Runtime APIs in desktop apps.

Configure the app manifest

Before your app can authenticate users using smart cards or virtual smart cards, you must set the **Shared User Certificates** capability in the project Package.appxmanifest file of your WinUI project or packaging project.

Access connected card readers and smart cards

You can query for readers and attached smart cards by passing the device ID (specified in DeviceInformation) to the SmartCardReader.FromIdAsync method. To access the smart cards currently attached to the returned reader device, call SmartCardReader.FindAllCardsAsync.

cs

```
string selector = SmartCardReader.GetDeviceSelector();
DeviceInformationCollection devices =
    await DeviceInformation.FindAllAsync(selector);

foreach (DeviceInformation device in devices)
{
    SmartCardReader reader =
        await SmartCardReader.FromIdAsync(device.Id);

    // For each reader, we want to find all the cards associated
    // with it. Then we will create a SmartCardListItem for
    // each (reader, card) pair.
    IReadOnlyList<SmartCard> cards =
```

```
        await reader.FindAllCardsAsync();
}
```

You should also enable your app to observe for CardAdded events by implementing a method to handle app behavior on card insertion.

cs

```
private void reader_CardAdded(SmartCardReader sender, CardAddedEventArgs
args)
{
  // A card has been inserted into the sender SmartCardReader.
}
```

You can then pass each returned SmartCard object to SmartCardProvisioning to access the methods that allow your app to access and customize its configuration.

Create a virtual smart card

To create a virtual smart card using SmartCardProvisioning, your app will first need to provide a friendly name, an admin key, and a SmartCardPinPolicy. The friendly name is generally something provided to the app, but your app will still need to provide an admin key and generate an instance of the current **SmartCardPinPolicy** before passing all three values to RequestVirtualSmartCardCreationAsync.

1. Create a new instance of a SmartCardPinPolicy
2. Generate the admin key value by calling CryptographicBuffer.GenerateRandom on the admin key value provided by the service or management tool.
3. Pass these values along with the *FriendlyNameText* string to RequestVirtualSmartCardCreationAsync.

cs

```
var pinPolicy = new SmartCardPinPolicy
    {
        MinLength = 6
    };

IBuffer adminkey = CryptographicBuffer.GenerateRandom(24);

SmartCardProvisioning provisioning = await
     SmartCardProvisioning.RequestVirtualSmartCardCreationAsync(
          "Card friendly name",
          adminkey,
          pinPolicy);
```

Once RequestVirtualSmartCardCreationAsync has returned the associated SmartCardProvisioning object, the virtual smart card is provisioned and ready for use.

> **Note**
>
> In order to create a virtual smart card using a packaged Windows app, the user running the app must be a member of the administrators group. If the user is not a member of the administrators group, virtual smart card creation will fail.

Handle authentication challenges

To authenticate with smart cards or virtual smart cards, your app must provide the behavior to complete challenges between the admin key data stored on the card, and the admin key data maintained by the authentication server or management tool.

The following code shows how to support smart card authentication for services or modification of physical or virtual card details. If the data generated using the admin key on the card ("challenge") is the same as the admin key data provided by the server or management tool ("adminkey"), authentication is successful.

cs

```
static class ChallengeResponseAlgorithm
{
    public static IBuffer CalculateResponse(IBuffer challenge, IBuffer
adminkey)
    {
        if (challenge == null)
            throw new ArgumentNullException("challenge");
        if (adminkey == null)
            throw new ArgumentNullException("adminkey");

        SymmetricKeyAlgorithmProvider objAlg =
SymmetricKeyAlgorithmProvider.OpenAlgorithm(SymmetricAlgorithmNames.TripleDe
sCbc);
        var symmetricKey = objAlg.CreateSymmetricKey(adminkey);
        var buffEncrypted = CryptographicEngine.Encrypt(symmetricKey,
challenge, null);
        return buffEncrypted;
    }
}
```

You will see this code referenced throughout the remainder of this topic was we review how to complete an authentication action, and how to apply changes to smart card and virtual smart card information.

Verify smart card or virtual smart card authentication response

Now that we have the logic for authentication challenges defined, we can communicate with the reader to access the smart card, or alternatively, access a virtual smart card for authentication.

1. To begin the challenge, call GetChallengeContextAsync from the SmartCardProvisioning object associated with the smart card. This will generate an instance of SmartCardChallengeContext, which contains the card's Challenge value.
2. Next, pass the card's challenge value and the admin key provided by the service or management tool to the **ChallengeResponseAlgorithm** that we defined in the previous example.
3. VerifyResponseAsync will return **true** if authentication is successful.

cs

```
bool verifyResult = false;
SmartCard card = await rootPage.GetSmartCard();
SmartCardProvisioning provisioning =
    await SmartCardProvisioning.FromSmartCardAsync(card);

SmartCardChallengeContext context =
    await provisioning.GetChallengeContextAsync();

IBuffer response = ChallengeResponseAlgorithm.CalculateResponse(
    context.Challenge,
    rootPage.AdminKey);

verifyResult = await context.VerifyResponseAsync(response);
```

Change or reset a user PIN

To change the PIN associated with a smart card:

1. Access the card and generate the associated SmartCardProvisioning object.
2. Call RequestPinChangeAsync to display a UI to the user to complete this operation.
3. If the PIN was successfully changed the call will return **true**.

cs

```
SmartCardProvisioning provisioning =
    await SmartCardProvisioning.FromSmartCardAsync(card);
```

```
bool result = await provisioning.RequestPinChangeAsync();
```

To request a PIN reset:

1. Call RequestPinResetAsync to initiate the operation. This call includes a SmartCardPinResetHandler method that represents the smart card and the pin reset request.
2. SmartCardPinResetHandler provides information that our **ChallengeResponseAlgorithm**, wrapped in a SmartCardPinResetDeferral call, uses to compare the card's challenge value and the admin key provided by the service or management tool to authenticate the request.
3. If the challenge is successful, the RequestPinResetAsync call is completed; returning **true** if the PIN was successfully reset.

cs

```
SmartCardProvisioning provisioning =
    await SmartCardProvisioning.FromSmartCardAsync(card);

bool result = await provisioning.RequestPinResetAsync(
    (pinResetSender, request) =>
    {
        SmartCardPinResetDeferral deferral =
            request.GetDeferral();

        try
        {
            IBuffer response =
                ChallengeResponseAlgorithm.CalculateResponse(
                    request.Challenge,
                    rootPage.AdminKey);
            request.SetResponse(response);
        }
        finally
        {
            deferral.Complete();
        }
    });
}
```

Remove a smart card or virtual smart card

When a physical smart card is removed a CardRemoved event will fire when the card is deleted.

Associate the firing of this event with the card reader with the method that defines your app's behavior on card or reader removal as an event handler. This behavior can be something as simply as providing notification to the user that the card was removed.

```cs
reader = card.Reader;
reader.CardRemoved += HandleCardRemoved;
```

The removal of a virtual smart card is handled programmatically by first retrieving the card and then calling RequestVirtualSmartCardDeletionAsync from the SmartCardProvisioning returned object.

```cs
bool result = await SmartCardProvisioning
    .RequestVirtualSmartCardDeletionAsync(card);
```

Create a Windows Hello login app

Article • 07/11/2024

This is the first part of a complete walkthrough on how to create a packaged Windows app that uses Windows Hello as an alternative to traditional username and password authentication systems. In this case, the app is a WinUI app, but the same approach can be used with any packaged Windows app, including WPF and Windows Forms apps. The app uses a username for sign-in and creates a Hello key for each account. These accounts will be protected by the PIN that is set up in Windows Settings on configuration of Windows Hello.

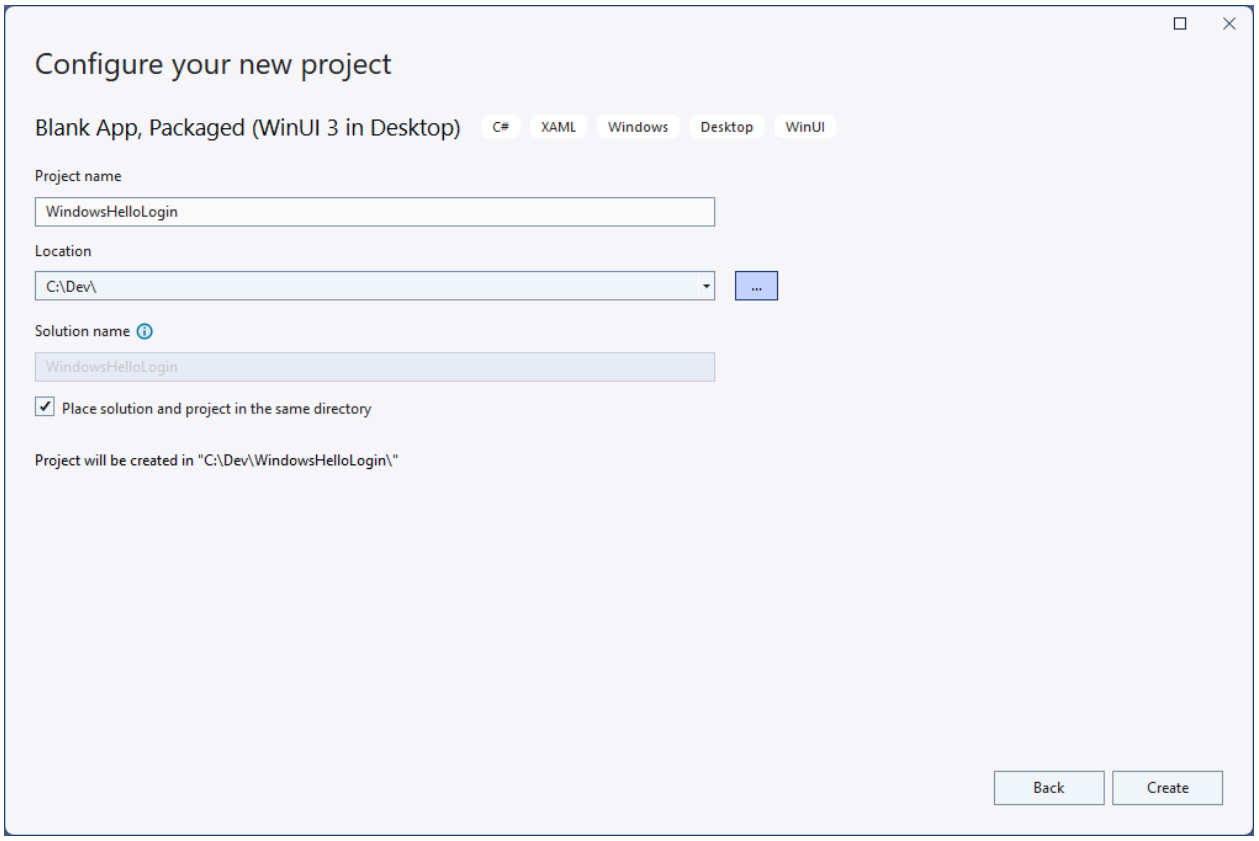
This walkthrough is split into two parts: building the app and connecting the backend service. When you're finished with this article, continue on to Part 2: Windows Hello login service.

Before you begin, you should read the Windows Hello overview for a general understanding of how Windows Hello works.

Get started

In order to build this project, you'll need some experience with C#, and XAML. You'll also need to be using Visual Studio 2022 on a Windows 10 or Windows 11 machine. See Start developing Windows apps for complete instructions on setting up your development environment.

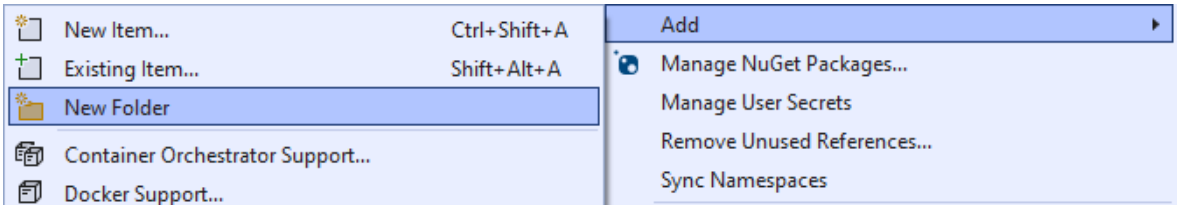
- In Visual Studio, select **File** > **New** > **Project**.
- In the **New Project** dialog's drop-down filters, select **C#/C++**, **Windows**, and **WinUI**, respectively.
- Choose **Blank App, Packaged (WinUI 3 in Desktop)** and name your application "WindowsHelloLogin".
- Build and Run the new application (F5), you should see a blank window shown on the screen. Close the application.



Exercise 1: Login with Windows Hello

In this exercise you will learn how to check if Windows Hello is setup on the machine, and how to sign into an account using Windows Hello.

- In the new project create a new folder in the solution called "Views". This folder will contain the pages that will be navigated to in this sample. Right-click the project in **Solution Explorer**, select **Add** > **New Folder**, then rename the folder to **Views**.

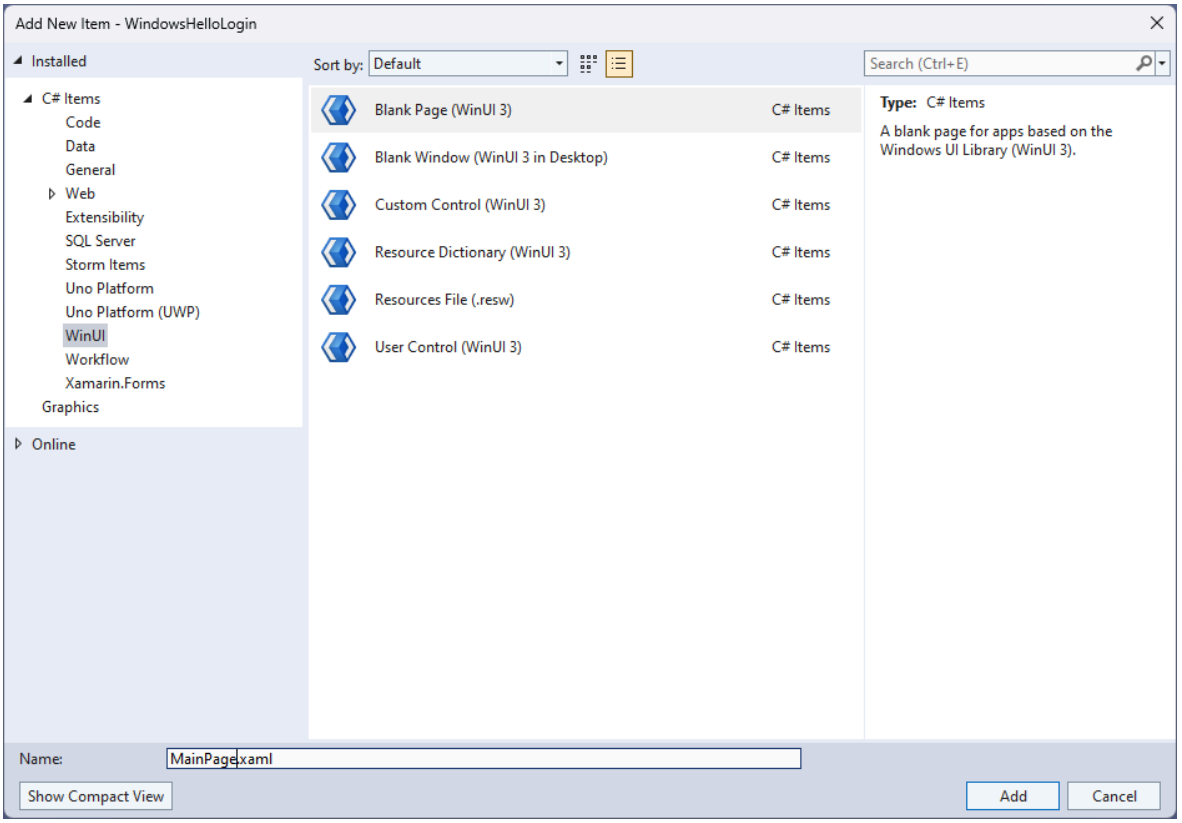


- Open MainWindow.xaml and replace the `Window` contents with an empty `StackPanel` or `Grid` control. We will be implementing page navigation and navigating to a new page when the **MainWindow** is loaded, so we don't need any content in the **MainWindow**.

- Add a `Title` property to **MainWindow** in the XAML. The attribute should look like this: `Title="Windows Hello Login"`.

- Remove the myButton_Click event handler from MainWindow.xaml.cs to avoid any compilation errors. This event handler is not needed for this sample.

- Right-click the new **Views** folder, select **Add** > **New Item** and select the **Blank Page** template. Name this page "MainPage.xaml".



- Open the App.xaml.cs file and update the **OnLaunched** handler to implement page navigation for the app. You'll also need to add a **RootFrame_NavigationFailed** handler method to deal with any errors that occur while loading pages.

```cs
protected override void
OnLaunched(Microsoft.UI.Xaml.LaunchActivatedEventArgs args)
{
    m_window = new MainWindow();
    var rootFrame = new Frame();
    rootFrame.NavigationFailed += RootFrame_NavigationFailed;
    rootFrame.Navigate(typeof(MainPage), args);
    m_window.Content = rootFrame;
    m_window.Activate();
}

private void RootFrame_NavigationFailed(object sender,
NavigationFailedEventArgs e)
{
    throw new Exception($"Error loading page
{e.SourcePageType.FullName}");
}
```

- You'll also need to add four using statements to the top of the App.xaml.cs file to resolve compilation errors in the code.

cs

```
using Microsoft.UI.Xaml.Controls;
using Microsoft.UI.Xaml.Navigation;
using System;
using WindowsHelloLogin.Views;
```

- Right-click the new **Views** folder, select **Add** > **New Item** and select the **Blank Page** template. Name this page "Login.xaml".
- To define the user interface for the new login page, add the following XAML. This XAML defines a `StackPanel` to align the following children:
  - A `TextBlock` that will contain a title.
  - A `TextBlock` for error messages.
  - A `TextBox` for the username to be input.
  - A `Button` to navigate to a register page.
  - A `TextBlock` to contain the status of Windows Hello.
  - A `TextBlock` to explain the Login page, as there is no backend or configured users yet.

XML

```
<Grid>
  <StackPanel>
    <TextBlock Text="Login" FontSize="36" Margin="4"
TextAlignment="Center"/>
    <TextBlock x:Name="ErrorMessage" Text="" FontSize="20"
Margin="4" Foreground="Red" TextAlignment="Center"/>
    <TextBlock Text="Enter your username below" Margin="0,0,0,20"
               TextWrapping="Wrap" Width="300"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>
    <TextBox x:Name="UsernameTextBox" Margin="4" Width="250"/>
    <Button x:Name="LoginButton" Content="Login"
Background="DodgerBlue" Foreground="White"
            Click="LoginButton_Click" Width="80"
HorizontalAlignment="Center" Margin="0,20"/>
    <TextBlock Text="Don't have an account?"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>
    <TextBlock x:Name="RegisterButtonTextBlock" Text="Register now"

PointerPressed="RegisterButtonTextBlock_OnPointerPressed"
               Foreground="DodgerBlue"
```

```
                TextAlignment="Center" VerticalAlignment="Center"
  FontSize="16"/>
      <Border x:Name="WindowsHelloStatus" Background="#22B14C"
              Margin="0,20" Height="100" >
        <TextBlock x:Name="WindowsHelloStatusText" Text="Windows Hello
  is ready to use!"
                   Margin="4" TextAlignment="Center"
  VerticalAlignment="Center" FontSize="20"/>
      </Border>
      <TextBlock x:Name="LoginExplanation" FontSize="24"
  TextAlignment="Center" TextWrapping="Wrap"
                 Text="Please Note: To demonstrate a login, validation
  will only occur using the default username 'sampleUsername'"/>
    </StackPanel>
  </Grid>
```

- A few methods need to be added to the code-behind file to get the solution building. Either press F7 or use the **Solution Explorer** to edit the Login.xaml.cs file. Add in the following two event methods to handle the **Login** and **Register** events. For now these methods will set the `ErrorMessage.Text` to an empty string. Be sure to include the following using statements. They will be needed for the next steps.

cs

```
using Microsoft.UI.Xaml;
using Microsoft.UI.Xaml.Controls;
using Microsoft.UI.Xaml.Input;
using Microsoft.UI.Xaml.Media;
using Microsoft.UI.Xaml.Navigation;
using System;

namespace WindowsHelloLogin.Views
{
    public sealed partial class Login : Page
    {
        public Login()
        {
            this.InitializeComponent();
        }
        private void LoginButton_Click(object sender, RoutedEventArgs
e)
        {
            ErrorMessage.Text = "";
        }
        private void RegisterButtonTextBlock_OnPointerPressed(object
sender, PointerRoutedEventArgs e)
        {
            ErrorMessage.Text = "";
        }
    }
}
```

- In order to render the **Login** page, edit the **MainPage** code to navigate to the **Login** page when the **MainPage** is loaded. Open the MainPage.xaml.cs file. In **Solution Explorer**, double-click on MainPage.xaml.cs. If you can't find this click the little arrow next to MainPage.xaml to show the code-behind file. Create a **Loaded** event handler method that will navigate to the **Login** page.

```cs
namespace WindowsHelloLogin.Views
{
    public sealed partial class MainPage : Page
    {
        public MainPage()
        {
            this.InitializeComponent();
            Loaded += MainPage_Loaded;
        }

        private void MainPage_Loaded(object sender, RoutedEventArgs e)
        {
            Frame.Navigate(typeof(Login));
        }
    }
}
```

- In the **Login** page, you need to handle the `OnNavigatedTo` event to validate if Windows Hello is available on the current machine. In Login.xaml.cs, implement the following code. You'll notice that the WindowsHelloHelper object indicates that there's an error. That's because we haven't created this helper class yet.

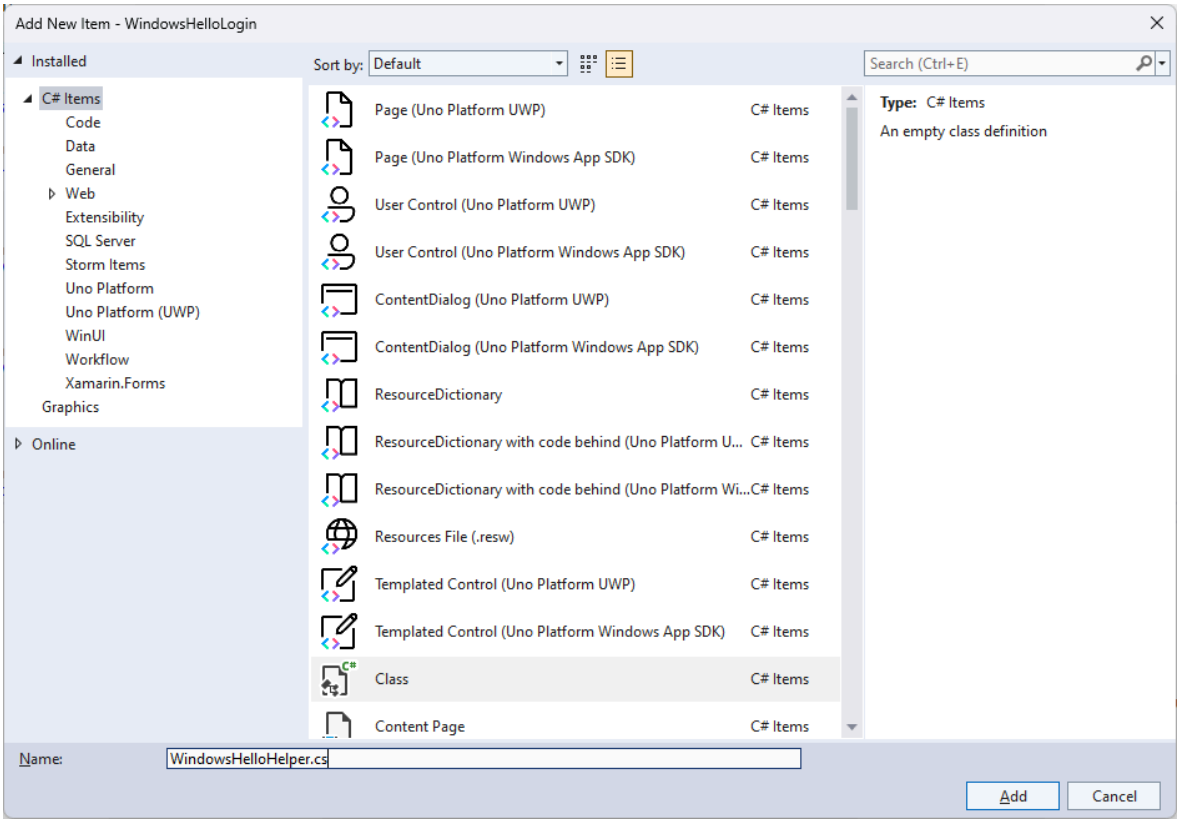
```cs
public sealed partial class Login : Page
{
    public Login()
    {
        this.InitializeComponent();
    }

    protected override async void OnNavigatedTo(NavigationEventArgs e)
    {
        // Check if Windows Hello is set up and available on this
machine
        if (await WindowsHelloHelper.WindowsHelloAvailableCheckAsync())
        {
        }
        else
        {
            // Windows Hello isn't set up, so inform the user
            WindowsHelloStatus.Background = new
```

```
SolidColorBrush(Windows.UI.Color.FromArgb(255, 50, 170, 207));
            WindowsHelloStatusText.Text = $"Windows Hello is not set
up!{Environment.NewLine}Please go to Windows Settings and set up a PIN
to use it.";
            LoginButton.IsEnabled = false;
        }
    }
}
```

- To create the WindowsHelloHelper class, right-click the **WindowsHelloLogin** project and click **Add** > **New Folder**. Name this folder **Utils**.

- Right click the **Utils** folder and select **Add** > **Class**. Name this new class "WindowsHelloHelper.cs".



- Change the scope of the **WindowsHelloHelper** class to be `public static`, then add the following method that to inform the user if Windows Hello is ready to be used or not. You will need to add the required namespaces.

cs

```
using System;
using System.Diagnostics;
using System.Threading.Tasks;
using Windows.Security.Credentials;

namespace WindowsHelloLogin.Utils
{
    public static class WindowsHelloHelper
```

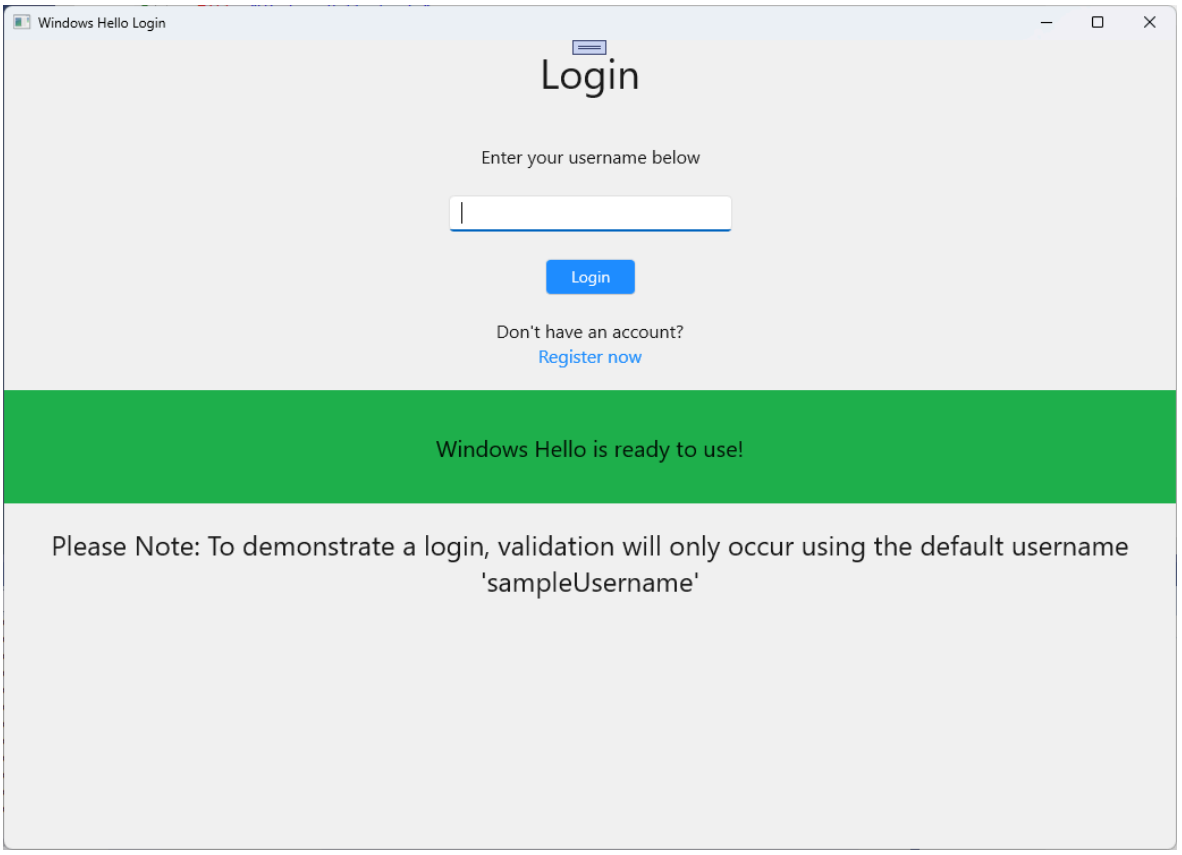
```
    {
        /// <summary>
        /// Checks to see if Windows Hello is ready to be used.
        ///
        /// Windows Hello has dependencies on:
        ///     1. Having a connected Microsoft Account
        ///     2. Having a Windows PIN set up for that account on the
local machine
        /// </summary>
        public static async Task<bool>
WindowsHelloAvailableCheckAsync()
        {
            bool keyCredentialAvailable = await
KeyCredentialManager.IsSupportedAsync();
            if (keyCredentialAvailable == false)
            {
                // Key credential is not enabled yet as user
                // needs to connect to a Microsoft Account and select a
PIN in the connecting flow.
                Debug.WriteLine("Windows Hello is not set up!\nPlease
go to Windows Settings and set up a PIN to use it.");
                return false;
            }

            return true;
        }
    }
}
```

- In Login.xaml.cs, add a reference to the `WindowsHelloLogin.Utils` namespace. This will resolve the error in the `OnNavigatedTo` method.

```cs
using WindowsHelloLogin.Utils;
```

- Build and run the application. You will be navigated to the login page and the Windows Hello banner will indicate to you if Windows Hello is ready to be used. You should see either the green or blue banner indicating the Windows Hello status on your machine.



- The next thing you need to do is build the logic for signing in. Create a new folder in the project named "Models".
- In the **Models** folder, create a new class called "Account.cs". This class will act as your account model. As this is a sample project, it will only contain a username. Change the class scope to `public` and add the `Username` property.

cs

```cs
namespace WindowsHelloLogin.Models
{
    public class Account
    {
        public string Username { get; set; }
    }
}
```

- The app needs a way to handle accounts. For this hands on lab, as there is no server or database, a list of users are saved and loaded locally. Right-click the **Utils** folder and add a new class named "AccountHelper.cs". Change the class scope to be `public static`. The **AccountHelper** is a static class that contains all the necessary methods to save and load the list of accounts locally. Saving and loading works by using an **XmlSerializer**. You also need to remember the file that was saved and where you saved it.

cs

```
using System;
using System.Collections.Generic;
using System.IO;
using System.Text;
using System.Threading.Tasks;
using System.Xml.Serialization;
using Windows.Storage;
using WindowsHelloLogin.Models;

namespace WindowsHelloLogin.Utils
{
    public static class AccountHelper
    {
        // In the real world this would not be needed as there would be
a server implemented that would host a user account database.
        // For this tutorial we will just be storing accounts locally.
        private const string USER_ACCOUNT_LIST_FILE_NAME =
"accountlist.txt";
        private static string _accountListPath =
Path.Combine(ApplicationData.Current.LocalFolder.Path,
USER_ACCOUNT_LIST_FILE_NAME);
        public static List<Account> AccountList = [];

        /// <summary>
        /// Create and save a useraccount list file. (Updating the old
one)
        /// </summary>
        private static async void SaveAccountListAsync()
        {
            string accountsXml = SerializeAccountListToXml();

            if (File.Exists(_accountListPath))
            {
                StorageFile accountsFile = await
StorageFile.GetFileFromPathAsync(_accountListPath);
                await FileIO.WriteTextAsync(accountsFile, accountsXml);
            }
            else
            {
                StorageFile accountsFile = await
ApplicationData.Current.LocalFolder.CreateFileAsync(USER_ACCOUNT_LIST_F
ILE_NAME);
                await FileIO.WriteTextAsync(accountsFile, accountsXml);
            }
        }

        /// <summary>
        /// Gets the useraccount list file and deserializes it from XML
to a list of useraccount objects.
        /// </summary>
        /// <returns>List of useraccount objects</returns>
        public static async Task<List<Account>> LoadAccountListAsync()
        {
            if (File.Exists(_accountListPath))
```

```
            {
                StorageFile accountsFile = await
StorageFile.GetFileFromPathAsync(_accountListPath);

                string accountsXml = await
FileIO.ReadTextAsync(accountsFile);
                DeserializeXmlToAccountList(accountsXml);
            }

            return AccountList;
        }

        /// <summary>
        /// Uses the local list of accounts and returns an XML
formatted string representing the list
        /// </summary>
        /// <returns>XML formatted list of accounts</returns>
        public static string SerializeAccountListToXml()
        {
            var xmlizer = new XmlSerializer(typeof(List<Account>));
            var writer = new StringWriter();
            xmlizer.Serialize(writer, AccountList);

            return writer.ToString();
        }

        /// <summary>
        /// Takes an XML formatted string representing a list of
accounts and returns a list object of accounts
        /// </summary>
        /// <param name="listAsXml">XML formatted list of
accounts</param>
        /// <returns>List object of accounts</returns>
        public static List<Account> DeserializeXmlToAccountList(string
listAsXml)
        {
            var xmlizer = new XmlSerializer(typeof(List<Account>));
            TextReader textreader = new StreamReader(new
MemoryStream(Encoding.UTF8.GetBytes(listAsXml)));

            return AccountList = (xmlizer.Deserialize(textreader)) as
List<Account>;
        }
    }
}
```

- Next, implement a way to add and remove an account from the local list of accounts. These actions will each save the list. The final method that you'll need for this hands-on lab is a validation method. As there is no authorization server or database of users, this will validate against a single user which is hard-coded. These methods should be added to the **AccountHelper** class.

cs

```cs
public static Account AddAccount(string username)
{
    // Create a new account with the username
    var account = new Account() { Username = username };
    // Add it to the local list of accounts
    AccountList.Add(account);
    // SaveAccountList and return the account
    SaveAccountListAsync();
    return account;
}

public static void RemoveAccount(Account account)
{
    // Remove the account from the accounts list
    AccountList.Remove(account);
    // Re save the updated list
    SaveAccountListAsync();
}

public static bool ValidateAccountCredentials(string username)
{
    // In the real world, this method would call the server to
authenticate that the account exists and is valid.
    // However, for this tutorial, we'll just have an existing sample
user that's named "sampleUsername".
    // If the username is null or does not match "sampleUsername"
validation will fail.
    // In this case, the user should register a new Windows Hello user.

    if (string.IsNullOrEmpty(username))
    {
        return false;
    }

    if (!string.Equals(username, "sampleUsername"))
    {
        return false;
    }

    return true;
}
```

- The next thing you need to do is handle a sign in request from the user. In Login.xaml.cs, create a new private variable that will hold the current account logging in. Then add a new method named **SignInWindowsHelloAsync**. This will validate the account credentials using the **AccountHelper.ValidateAccountCredentials** method. This method will return a **Boolean** value if the entered user name is the same as the hard coded string value

you configured in the previous step. The hard-coded value for this sample is "sampleUsername".

cs

```
using WindowsHelloLogin.Models;
using WindowsHelloLogin.Utils;
using System.Diagnostics;
using System.Threading.Tasks;

namespace WindowsHelloLogin.Views
{
    public sealed partial class Login : Page
    {
        private Account _account;

        public Login()
        {
            this.InitializeComponent();
        }

        protected override async void OnNavigatedTo(NavigationEventArgs
e)
        {
            // Check if Windows Hello is set up and available on this
machine
            if (await
WindowsHelloHelper.WindowsHelloAvailableCheckAsync())
            {
            }
            else
            {
                // Windows Hello is not set up, so inform the user
                WindowsHelloStatus.Background = new
SolidColorBrush(Windows.UI.Color.FromArgb(255, 50, 170, 207));
                WindowsHelloStatusText.Text = "Windows Hello is not set
up!\nPlease go to Windows Settings and set up a PIN to use it.";
                LoginButton.IsEnabled = false;
            }
        }

        private async void LoginButton_Click(object sender,
RoutedEventArgs e)
        {
            ErrorMessage.Text = "";
            await SignInWindowsHelloAsync();
        }

        private void RegisterButtonTextBlock_OnPointerPressed(object
sender, PointerRoutedEventArgs e)
        {
            ErrorMessage.Text = "";
        }
```

```
        private async Task SignInWindowsHelloAsync()
        {
            if
(AccountHelper.ValidateAccountCredentials(UsernameTextBox.Text))
            {
                // Create and add a new local account
                _account =
AccountHelper.AddAccount(UsernameTextBox.Text);
                Debug.WriteLine("Successfully signed in with
traditional credentials and created local account instance!");

                //if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(UsernameTextBox.Text))
                //{
                //    Debug.WriteLine("Successfully signed in with
Windows Hello!");
                //}
            }
            else
            {
                ErrorMessage.Text = "Invalid Credentials";
            }
        }
    }
}
```

- You may have noticed the commented code that was referencing a method in **WindowsHelloHelper**. In WindowsHelloHelper.cs, add a new method named **CreateWindowsHelloKeyAsync**. This method uses the Windows Hello API in the KeyCredentialManager. Calling RequestCreateAsync will create a Windows Hello key that is specific to the *accountId* and the local machine. Please note the comments in the switch statement if you are interested in implementing this in a real world scenario.

cs

```
/// <summary>
/// Creates a Windows Hello key on the machine using the account ID
provided.
/// </summary>
/// <param name="accountId">The account ID associated with the account
that we are enrolling into Windows Hello</param>
/// <returns>Boolean indicating if creating the Windows Hello key
succeeded</returns>
public static async Task<bool> CreateWindowsHelloKeyAsync(string
accountId)
{
    KeyCredentialRetrievalResult keyCreationResult = await
KeyCredentialManager.RequestCreateAsync(accountId,
KeyCredentialCreationOption.ReplaceExisting);
```

```
    switch (keyCreationResult.Status)
    {
        case KeyCredentialStatus.Success:
            Debug.WriteLine("Successfully created key");

            // In the real world, authentication would take place on a
server.
            // So, every time a user migrates or creates a new Windows
Hello
            // account, details should be pushed to the server.
            // The details that would be pushed to the server include:
            // The public key, keyAttestation (if available),
            // certificate chain for attestation endorsement key (if
available),
            // status code of key attestation result:
keyAttestationIncluded or
            // keyAttestationCanBeRetrievedLater and
keyAttestationRetryType.
            // As this sample has no concept of a server, it will be
skipped for now.
            // For information on how to do this, refer to the second
sample.

            // For this sample, just return true
            return true;
        case KeyCredentialStatus.UserCanceled:
            Debug.WriteLine("User cancelled sign-in process.");
            break;
        case KeyCredentialStatus.NotFound:
            // User needs to set up Windows Hello
            Debug.WriteLine("Windows Hello is not set up!\nPlease go to
Windows Settings and set up a PIN to use it.");
            break;
        default:
            break;
    }

    return false;
}
```

- Now that you have created the **CreateWindowsHelloKeyAsync** method, return to the Login.xaml.cs file and uncomment the code inside the SignInWindowsHelloAsync method.

cs

```
private async void SignInWindowsHelloAsync()
{
    if (AccountHelper.ValidateAccountCredentials(UsernameTextBox.Text))
    {
        //Create and add a new local account
        _account = AccountHelper.AddAccount(UsernameTextBox.Text);
        Debug.WriteLine("Successfully signed in with traditional
```

```
credentials and created local account instance!");

        if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(UsernameTextBox.Text))
        {
            Debug.WriteLine("Successfully signed in with Windows
Hello!");
        }
    }
    else
    {
        ErrorMessage.Text = "Invalid Credentials";
    }
}
```

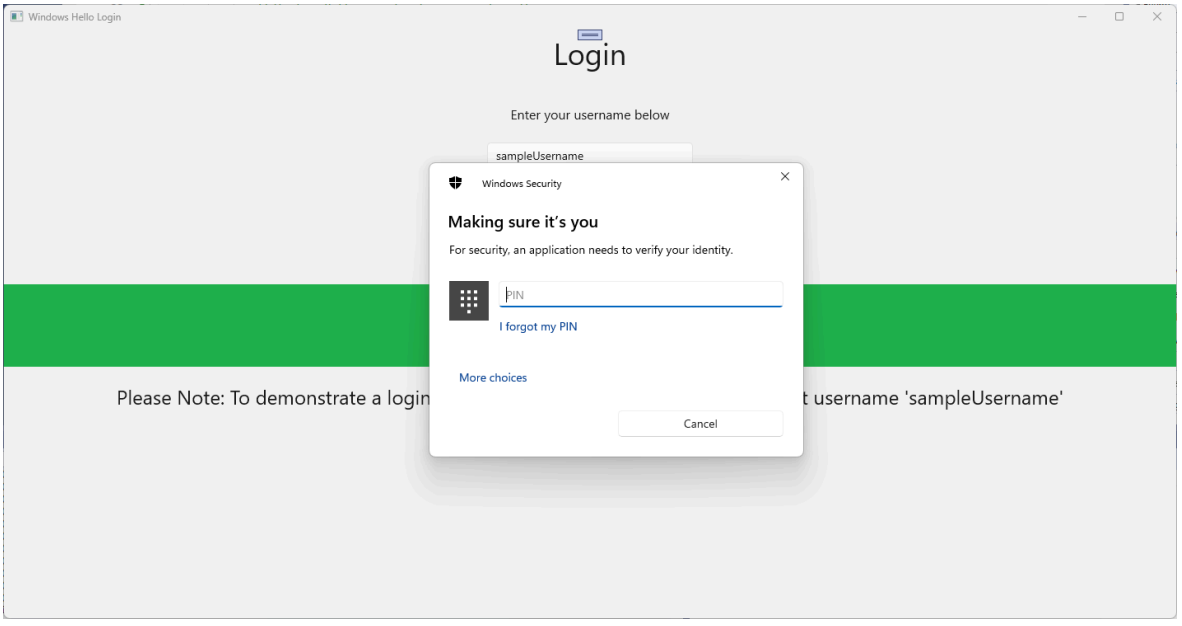
- Build and run the application. You will be taken to the Login page. Enter the user name as "sampleUsername" and click login. You will be prompted with a Windows Hello prompt asking you to enter your PIN. Upon entering your PIN correctly, the **CreateWindowsHelloKeyAsync** method will be able to create a Windows Hello key. Monitor the output windows to see if the messages indicating success are shown.



Exercise 2: Welcome and User Selection Pages

In this exercise, you will continue from the previous exercise. When a user successfully logs in, they should be taken to a welcome page where they can sign out or delete their account. As Windows Hello creates a key for every machine, a user selection screen can be created, which displays all users that have been signed in on that machine. A user can then select one of these accounts and go directly to the welcome screen without needed to re-enter a password as they have already authenticated to access the machine.

- In the **Views** folder add a new blank page named "Welcome.xaml". Add the following XAML to complete the user interface for the page. This will display a title, the logged in username, and two buttons. One of the buttons will navigate back to a user list (that you will create later), and the other button will handle forgetting this user.

XML

```
<Grid>
  <StackPanel>
    <TextBlock x:Name="Title" Text="Welcome" FontSize="40"
TextAlignment="Center"/>
    <TextBlock x:Name="UserNameText" FontSize="28"
TextAlignment="Center"/>

    <Button x:Name="BackToUserListButton" Content="Back to User List"
Click="Button_Restart_Click"
            HorizontalAlignment="Center" Margin="0,20"
Foreground="White" Background="DodgerBlue"/>

    <Button x:Name="ForgetButton" Content="Forget Me"
Click="Button_Forget_User_Click"
            Foreground="White"
            Background="Gray"
            HorizontalAlignment="Center"/>
  </StackPanel>
</Grid>
```

- In the Welcome.xaml.cs code-behind file, add a new private variable that will hold the account that is logged in. You will need to implement a method to override the `OnNavigateTo` event, this will store the account passed to the **Welcome** page. You will also need to implement the `Click` event for the two buttons defined in the XAML. You will need to add using statements for the `WindowsHelloLogin.Models` and `WindowsHelloLogin.Utils` namespaces.

cs

```
using WindowsHelloLogin.Models;
using WindowsHelloLogin.Utils;
using System.Diagnostics;

namespace WindowsHelloLogin.Views
{
    public sealed partial class Welcome : Page
    {
        private Account _activeAccount;

        public Welcome()
        {
```

```
            InitializeComponent();
        }

        protected override void OnNavigatedTo(NavigationEventArgs e)
        {
            _activeAccount = (Account)e.Parameter;
            if (_activeAccount != null)
            {
                UserNameText.Text = _activeAccount.Username;
            }
        }

        private void Button_Restart_Click(object sender,
RoutedEventArgs e)
        {
        }

        private void Button_Forget_User_Click(object sender,
RoutedEventArgs e)
        {
            // Remove the account from Windows Hello
            //
WindowsHelloHelper.RemoveWindowsHelloAccountAsync(_activeAccount);

            // Remove it from the local accounts list and re-save the
updated list
            AccountHelper.RemoveAccount(_activeAccount);

            Debug.WriteLine($"User {_activeAccount.Username}
deleted.");
        }
    }
}
```

- You may have noticed a line commented out in the `Button_Forget_User_Click` event handler. The account is being removed from your local list but currently there is no way to be removed from Windows Hello. You need to implement a new method in WindowsHelloHelper.cs that will handle removing a Windows Hello user. This method will use other Windows Hello APIs to open and delete the account. In the real world, when you delete an account the server or database should be notified so the user database remains valid. You will need a using statement referencing the `WindowsHelloLogin.Models` namespace.

cs

```
using WindowsHelloLogin.Models;

/// <summary>
/// Function to be called when user requests deleting their account.
/// Checks the KeyCredentialManager to see if there is a Windows Hello
/// account for the current user.
```

```
/// It then deletes the local key associated with the account.
/// </summary>
public static async void RemoveWindowsHelloAccountAsync(Account
account)
{
    // Open the account with Windows Hello
    KeyCredentialRetrievalResult keyOpenResult = await
KeyCredentialManager.OpenAsync(account.Username);

    if (keyOpenResult.Status == KeyCredentialStatus.Success)
    {
        // In the real world you would send key information to server
to unregister
        //for example, RemoveWindowsHelloAccountOnServer(account);
    }

    // Then delete the account from the machine's list of Windows Hello
accounts
    await KeyCredentialManager.DeleteAsync(account.Username);
}
```

- Back in Welcome.xaml.cs, uncomment the line that calls **RemoveWindowsHelloAccountAsync**.

cs

```
private void Button_Forget_User_Click(object sender, RoutedEventArgs e)
{
    // Remove it from Windows Hello
    WindowsHelloHelper.RemoveWindowsHelloAccountAsync(_activeAccount);

    // Remove it from the local accounts list and re-save the updated
list
    AccountHelper.RemoveAccount(_activeAccount);

    Debug.WriteLine($"User {_activeAccount.Username} deleted.");
}
```

- In the **SignInWindowsHelloAsync** method (in Login.xaml.cs), once the **CreateWindowsHelloKeyAsync** is successful, it should navigate to the **Welcome** page and pass the **Account**.

cs

```
private async void SignInWindowsHelloAsync()
{
    if (AccountHelper.ValidateAccountCredentials(UsernameTextBox.Text))
    {
        // Create and add a new local account
        _account = AccountHelper.AddAccount(UsernameTextBox.Text);
        Debug.WriteLine("Successfully signed in with traditional
```

```
credentials and created local account instance!");

        if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(UsernameTextBox.Text))
        {
            Debug.WriteLine("Successfully signed in with Windows
Hello!");
            Frame.Navigate(typeof(Welcome), _account);
        }
    }
    else
    {
        ErrorMessage.Text = "Invalid Credentials";
    }
}
```

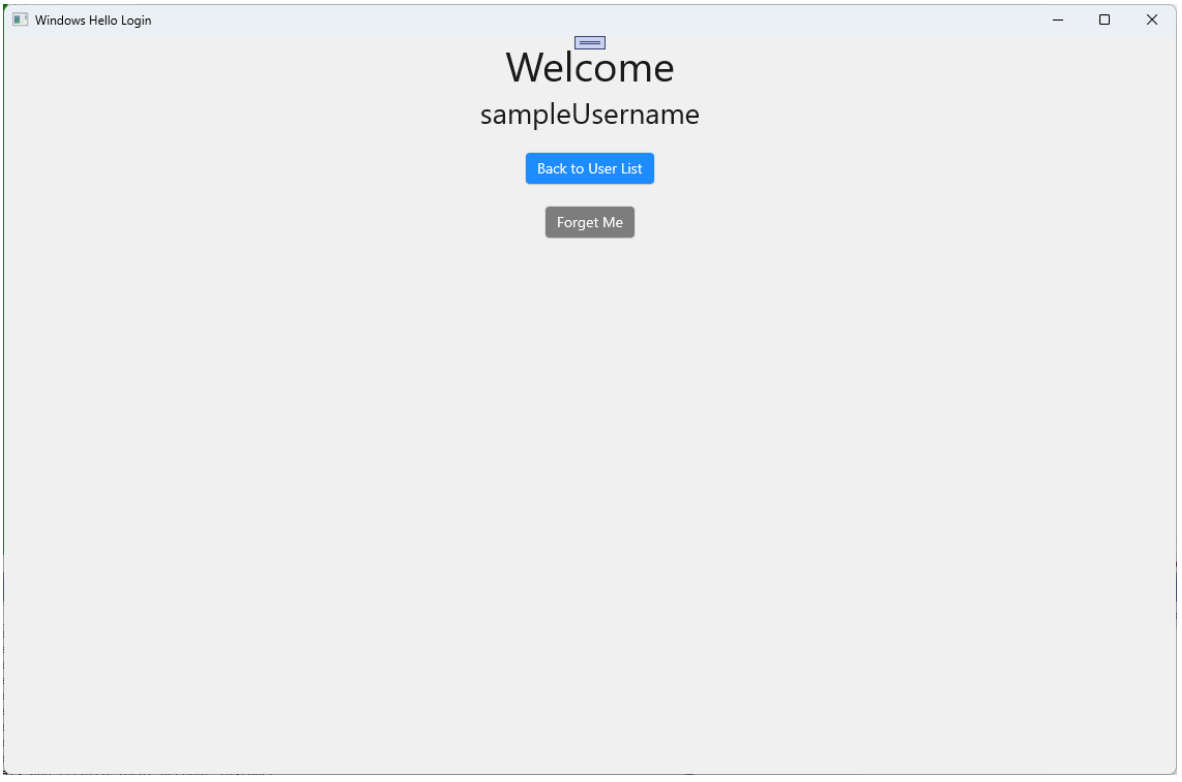
- Build and run the application. Login with "sampleUsername" and click **Login**. Enter your PIN and if successful you should be navigated to the **Welcome** screen. Try clicking **Forget User** and monitor Visual Studio's **Output** window to see if the user was deleted. Notice that when the user is deleted, you remain on the **Welcome** page. You'll need to create a user selection page to which the app can navigate.



- In the **Views** folder, create a new blank page named "UserSelection.xaml" and add the following XAML to define the user interface. This page will contain a ListView that displays all the users in the local accounts list, and a `Button` that will navigate to the **Login** page to allow the user to add another account.

```
XML
```

```
<Grid>
  <StackPanel>
    <TextBlock x:Name="Title" Text="Select a User" FontSize="36"
Margin="4" TextAlignment="Center" HorizontalAlignment="Center"/>

    <ListView x:Name="UserListView" Margin="4" MaxHeight="200"
MinWidth="250" Width="250" HorizontalAlignment="Center">
      <ListView.ItemTemplate>
        <DataTemplate>
          <Grid Background="DodgerBlue" Height="50" Width="250"
HorizontalAlignment="Stretch" VerticalAlignment="Stretch">
            <TextBlock Text="{Binding Username}"
HorizontalAlignment="Center" TextAlignment="Center"
VerticalAlignment="Center" Foreground="White"/>
          </Grid>
        </DataTemplate>
      </ListView.ItemTemplate>
    </ListView>

    <Button x:Name="AddUserButton" Content="+" FontSize="36" Width="60"
Click="AddUserButton_Click" HorizontalAlignment="Center"/>
  </StackPanel>
</Grid>
```

- In UserSelection.xaml.cs, implement the `Loaded` method that will navigate to the **Login** page if there are no accounts in the local list. Also implement the `SelectionChanged` event for the `ListView` and a `Click` event for the `Button`.

cs

```
using System.Diagnostics;
using WindowsHelloLogin.Models;
using WindowsHelloLogin.Utils;

namespace WindowsHelloLogin.Views
{
    public sealed partial class UserSelection : Page
    {
        public UserSelection()
        {
            InitializeComponent();
            Loaded += UserSelection_Loaded;
        }

        private void UserSelection_Loaded(object sender,
RoutedEventArgs e)
        {
            if (AccountHelper.AccountList.Count == 0)
            {
                // If there are no accounts, navigate to the Login page
                Frame.Navigate(typeof(Login));
```

```
            }

            UserListView.ItemsSource = AccountHelper.AccountList;
            UserListView.SelectionChanged += UserSelectionChanged;
        }

        /// <summary>
        /// Function called when an account is selected in the list of
accounts
        /// Navigates to the Login page and passes the chosen account
        /// </summary>
        private void UserSelectionChanged(object sender,
RoutedEventArgs e)
        {
            if (((ListView)sender).SelectedValue != null)
            {
                Account account = (Account)
((ListView)sender).SelectedValue;
                if (account != null)
                {
                    Debug.WriteLine($"Account {account.Username}
selected!");
                }
                Frame.Navigate(typeof(Login), account);
            }
        }

        /// <summary>
        /// Function called when the "+" button is clicked to add a new
user.
        /// Navigates to the Login page with nothing filled out
        /// </summary>
        private void AddUserButton_Click(object sender, RoutedEventArgs
e)
        {
            Frame.Navigate(typeof(Login));
        }
    }
}
```

- There are a few places in the app where you want to navigate to the **UserSelection** page. In MainPage.xaml.cs, you should navigate to the **UserSelection** page instead of the **Login** page. While you are in the loaded event in **MainPage**, you will need to load the accounts list so the **UserSelection** page can check if there are any accounts. This will require changing the `Loaded` method to be async and also adding a using statement for the `WindowsHelloLogin.Utils` namespace.

```
cs
```

```
using WindowsHelloLogin.Utils;

private async void MainPage_Loaded(object sender, RoutedEventArgs e)
{
    // Load the local account list before navigating to the
UserSelection page
    await AccountHelper.LoadAccountListAsync();
    Frame.Navigate(typeof(UserSelection));
}
```

- Next, the app will need navigate to the **UserSelection** page from the **Welcome** page. In both `Click` events, you should navigate back to the **UserSelection** page.

cs

```
private void Button_Restart_Click(object sender, RoutedEventArgs e)
{
    Frame.Navigate(typeof(UserSelection));
}

private void Button_Forget_User_Click(object sender, RoutedEventArgs e)
{
    // Remove it from Windows Hello
    WindowsHelloHelper.RemoveWindowsHelloAccountAsync(_activeAccount);

    // Remove it from the local accounts list and re-save the updated
list
    AccountHelper.RemoveAccount(_activeAccount);

    Debug.WriteLine($"User {_activeAccount.Username} deleted.");

    // Navigate back to UserSelection page.
    Frame.Navigate(typeof(UserSelection));
}
```

- In the **Login** page, you need code to log in to the account selected from the list in the **UserSelection** page. In the `OnNavigatedTo` event, store the account passed during navigation. Start by adding a new private variable that will identify if the account is an existing account. Then handle the `OnNavigatedTo` event.

cs

```
namespace WindowsHelloLogin.Views
{
    public sealed partial class Login : Page
    {
        private Account _account;
        private bool _isExistingAccount;
```

```
        public Login()
        {
            InitializeComponent();
        }

        /// <summary>
        /// Function called when this frame is navigated to.
        /// Checks to see if Windows Hello is available and if an
account was passed in.
        /// If an account was passed in set the "_isExistingAccount"
flag to true and set the _account.
        /// </summary>
        protected override async void OnNavigatedTo(NavigationEventArgs
e)
        {
            // Check Windows Hello is set up and available on this
machine
            if (await
WindowsHelloHelper.WindowsHelloAvailableCheckAsync())
            {
                if (e.Parameter != null)
                {
                    _isExistingAccount = true;
                    // Set the account to the existing account being
passed in
                    _account = (Account)e.Parameter;
                    UsernameTextBox.Text = _account.Username;
                    await SignInWindowsHelloAsync();
                }
            }
            else
            {
                // Windows Hello is not set up, so inform the user
                WindowsHelloStatus.Background = new
SolidColorBrush(Windows.UI.Color.FromArgb(255, 50, 170, 207));
                WindowsHelloStatusText.Text = $"Windows Hello is not
set up!{Environment.NewLine}Please go to Windows Settings and set up a
PIN to use it.";
                LoginButton.IsEnabled = false;
            }
        }
    }
}
```

- The **SignInWindowsHelloAsync** method will need to be updated to sign in to the selected account. The **WindowsHelloHelper** will need another method to open the account with Windows Hello, as the account already has an account key created for it. Implement the new method in WindowsHelloHelper.cs to sign in an existing user with Windows Hello. For information on each part of the code, please read through the code comments.

```
cs
```

```
/// <summary>
/// Attempts to sign a message using the account key on the system for
the accountId passed.
/// </summary>
/// <returns>Boolean representing if creating the Windows Hello
authentication message succeeded</returns>
public static async Task<bool>
GetWindowsHelloAuthenticationMessageAsync(Account account)
{
    KeyCredentialRetrievalResult openKeyResult = await
KeyCredentialManager.OpenAsync(account.Username);
    // Calling OpenAsync will allow the user access to what is
available in the app and will not require user credentials again.
    // If you wanted to force the user to sign in again you can use the
following:
    // var consentResult = await
Windows.Security.Credentials.UI.UserConsentVerifier.RequestVerification
Async(account.Username);
    // This will ask for the either the password of the currently
signed in Microsoft Account or the PIN used for Windows Hello.

    if (openKeyResult.Status == KeyCredentialStatus.Success)
    {
        // If OpenAsync has succeeded, the next thing to think about is
whether the client application requires access to backend services.
        // If it does here you would request a challenge from the
server. The client would sign this challenge and the server
        // would check the signed challenge. If it is correct, it would
allow the user access to the backend.
        // You would likely make a new method called RequestSignAsync
to handle all this.
        // For example, RequestSignAsync(openKeyResult);
        // Refer to the second Windows Hello sample for information on
how to do this.

        // For this sample, there is not concept of a server
implemented so just return true.
        return true;
    }
    else if (openKeyResult.Status == KeyCredentialStatus.NotFound)
    {
        // If the account is not found at this stage. It could be one
of two errors.
        // 1. Windows Hello has been disabled
        // 2. Windows Hello has been disabled and re-enabled cause the
Windows Hello Key to change.
        // Calling CreateWindowsHelloKeyAsync and passing through the
account will attempt to replace the existing Windows Hello Key for that
account.
        // If the error really is that Windows Hello is disabled then
the CreateWindowsHelloKeyAsync method will output that error.
        if (await CreateWindowsHelloKeyAsync(account.Username))
        {
            // If the Hello Key was again successfully created, Windows
```

```
Hello has just been reset.
            // Now that the Hello Key has been reset for the account
retry sign in.
            return await
GetWindowsHelloAuthenticationMessageAsync(account);
        }
    }

    // Can't use Windows Hello right now, try again later
    return false;
}
```

- Update the **SignInWindowsHelloAsync** method in Login.xaml.cs to handle the existing account. This will use the new method in the WindowsHelloHelper.cs. If successful the account will be signed in and the user navigated to the **Welcome** page.

cs

```
private async Task SignInWindowsHelloAsync()
{
    if (_isExistingAccount)
    {
        if (await
WindowsHelloHelper.GetWindowsHelloAuthenticationMessageAsync(_account))
        {
            Frame.Navigate(typeof(Welcome), _account);
        }
    }
    else if
(AccountHelper.ValidateAccountCredentials(UsernameTextBox.Text))
    {
        //Create and add a new local account
        _account = AccountHelper.AddAccount(UsernameTextBox.Text);
        Debug.WriteLine("Successfully signed in with traditional
credentials and created local account instance!");

        if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(UsernameTextBox.Text))
        {
            Debug.WriteLine("Successfully signed in with Windows
Hello!");
            Frame.Navigate(typeof(Welcome), _account);
        }
    }
    else
    {
        ErrorMessage.Text = "Invalid Credentials";
    }
}
```

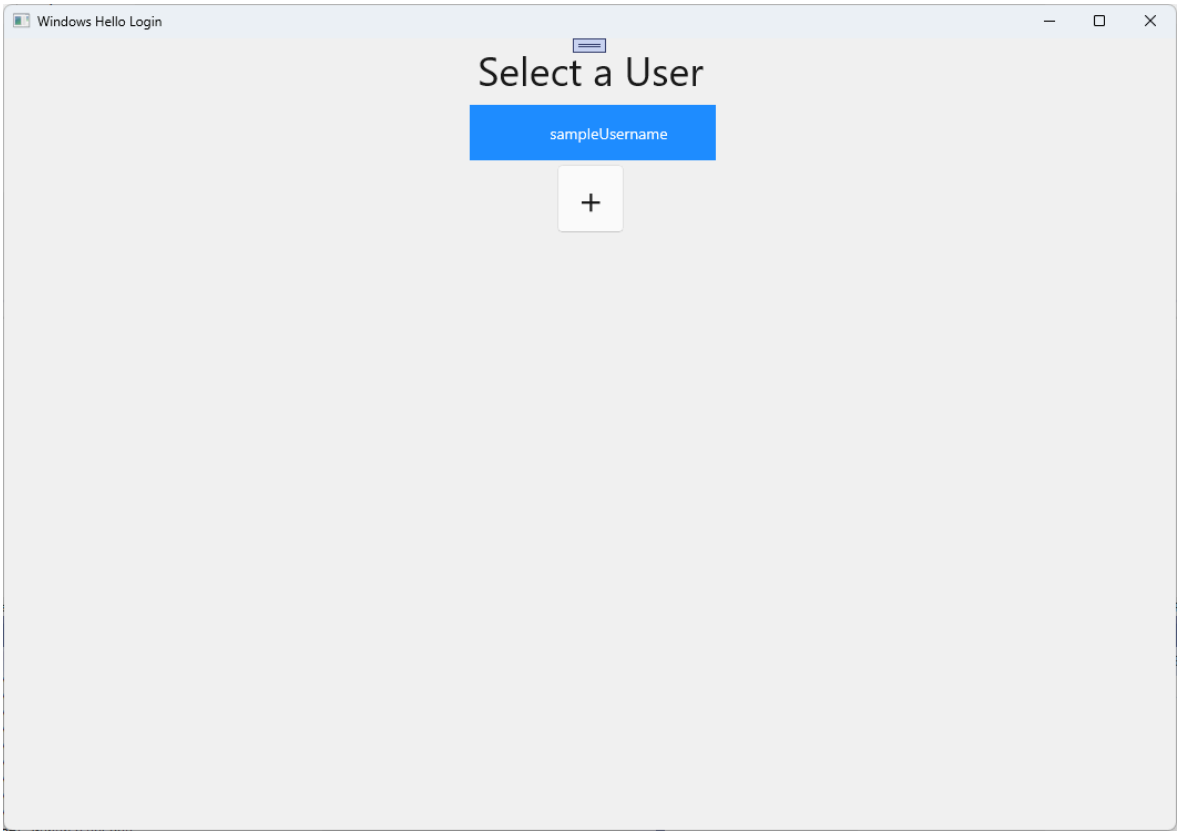
- Build and run the application. Login with "sampleUsername". Type in your PIN and if successful you will be navigated to the **Welcome** page. Click back to user list. You should now see a user in the list. If you click on this, WindowsHello enables you to sign back in without having to re-enter any passwords etc.



Exercise 3: Registering a new Windows Hello user

In this exercise, you create a new page that can create a new account with Windows Hello. This works similarly to how the **Login** page works. The **Login** page is implemented for an existing user that is migrating to use Windows Hello. A **WindowsHelloRegister** page will create Windows Hello registration for a new user.

- In the **Views** folder, create a new blank page named "WindowsHelloRegister.xaml". In the XAML add in the following to setup the user interface. The interface on this page is similar to the **Login** page.

XML

```
<Grid>
  <StackPanel>
    <TextBlock x:Name="Title" Text="Register New Windows Hello User"
FontSize="24" Margin="4" TextAlignment="Center"/>

    <TextBlock x:Name="ErrorMessage" Text="" FontSize="20" Margin="4"
```

```
Foreground="Red" TextAlignment="Center"/>

    <TextBlock Text="Enter your new username below" Margin="0,0,0,20"
               TextWrapping="Wrap" Width="300"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>

    <TextBox x:Name="UsernameTextBox" Margin="4" Width="250"/>

    <Button x:Name="RegisterButton" Content="Register"
Background="DodgerBlue" Foreground="White"
            Click="RegisterButton_Click_Async" Width="80"
HorizontalAlignment="Center" Margin="0,20"/>

    <Border x:Name="WindowsHelloStatus" Background="#22B14C" Margin="4"
Height="100">
      <TextBlock x:Name="WindowsHelloStatusText" Text="Windows Hello is
ready to use!" FontSize="20"
                 Margin="4" TextAlignment="Center"
VerticalAlignment="Center"/>
    </Border>
  </StackPanel>
</Grid>
```

- In the WindowsHelloRegister.xaml.cs code-behind file, implement a private `Account` variable and a `Click` event for the register button. This will add a new local account and create a Windows Hello key.

cs

```
using Microsoft.UI.Xaml.Controls;
using Microsoft.UI.Xaml;
using WindowsHelloLogin.Models;
using WindowsHelloLogin.Utils;

namespace WindowsHelloLogin.Views
{
    public sealed partial class WindowsHelloRegister : Page
    {
        private Account _account;

        public WindowsHelloRegister()
        {
            InitializeComponent();
        }

        private async void RegisterButton_Click_Async(object sender,
RoutedEventArgs e)
        {
            ErrorMessage.Text = "";

            // In the real world, you would validate the entered
```

```
credentials and information before
            // allowing a user to register a new account.
            // For this sample, we'll skip that step and just register
an account if the username is not null.

            if (!string.IsNullOrEmpty(UsernameTextBox.Text))
            {
                // Register a new account
                _account =
AccountHelper.AddAccount(UsernameTextBox.Text);
                // Register new account with Windows Hello
                await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(_account.Username);
                // Navigate to the Welcome page.
                Frame.Navigate(typeof(Welcome), _account);
            }
            else
            {
                ErrorMessage.Text = "Please enter a username";
            }
        }
    }
}
```

- You need to navigate to this page from the **Login** page when register is clicked.

cs

```
private void RegisterButtonTextBlock_OnPointerPressed(object sender,
PointerRoutedEventArgs e)
{
    ErrorMessage.Text = "";
    Frame.Navigate(typeof(WindowsHelloRegister));
}
```

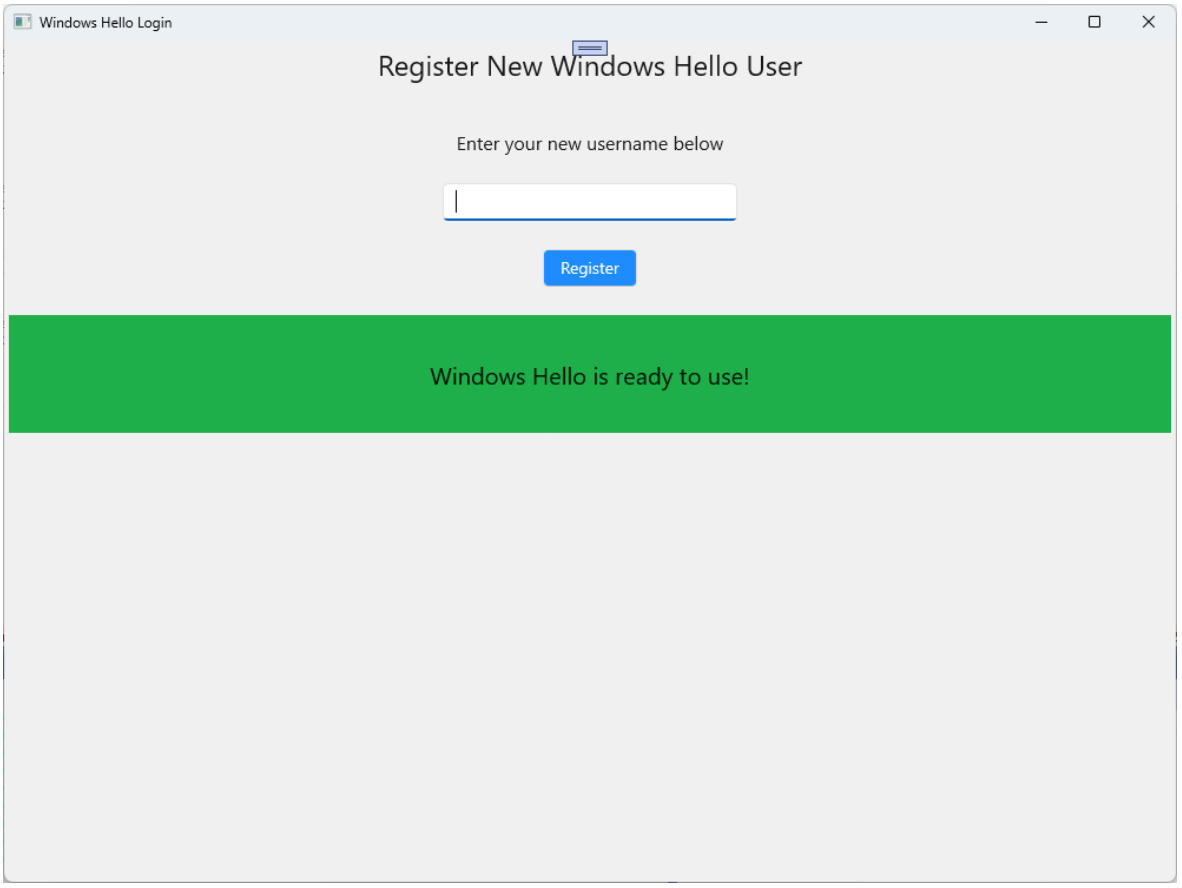
- Build and run the application. Try to register a new user. Then return to the user list and validate that you can select that user and login.



In this lab, you have learned the essential skills needed to use the new Windows Hello API to authenticate existing users and create accounts for new users. With this new knowledge, you can start removing the need for users to remember passwords for your application, yet remain confident that your applications remain protected by user authentication. Windows uses Windows Hello's new authentication technology to support its biometrics login options.

Create a Windows Hello login app

Article • 07/11/2024

This is the first part of a complete walkthrough on how to create a packaged Windows app that uses Windows Hello as an alternative to traditional username and password authentication systems. In this case, the app is a WinUI app, but the same approach can be used with any packaged Windows app, including WPF and Windows Forms apps. The app uses a username for sign-in and creates a Hello key for each account. These accounts will be protected by the PIN that is set up in Windows Settings on configuration of Windows Hello.

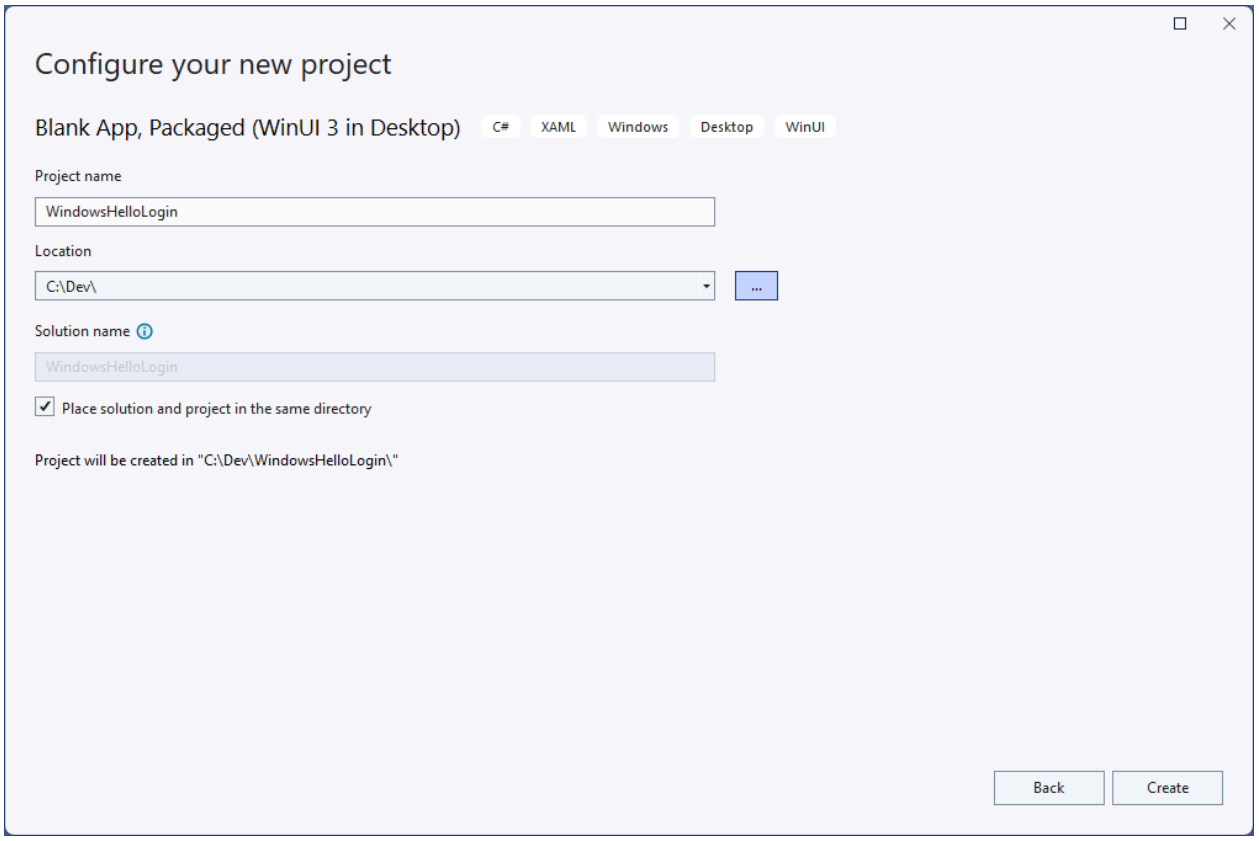
This walkthrough is split into two parts: building the app and connecting the backend service. When you're finished with this article, continue on to Part 2: Windows Hello login service.

Before you begin, you should read the Windows Hello overview for a general understanding of how Windows Hello works.

Get started

In order to build this project, you'll need some experience with C#, and XAML. You'll also need to be using Visual Studio 2022 on a Windows 10 or Windows 11 machine. See Start developing Windows apps for complete instructions on setting up your development environment.

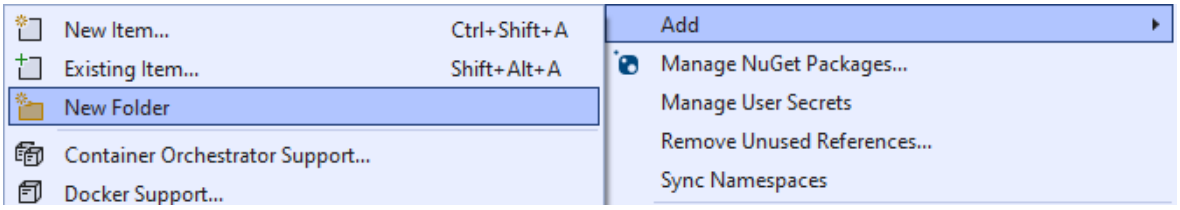
- In Visual Studio, select **File** > **New** > **Project**.
- In the **New Project** dialog's drop-down filters, select **C#/C++**, **Windows**, and **WinUI**, respectively.
- Choose **Blank App, Packaged (WinUI 3 in Desktop)** and name your application "WindowsHelloLogin".
- Build and Run the new application (F5), you should see a blank window shown on the screen. Close the application.



Exercise 1: Login with Windows Hello

In this exercise you will learn how to check if Windows Hello is setup on the machine, and how to sign into an account using Windows Hello.

- In the new project create a new folder in the solution called "Views". This folder will contain the pages that will be navigated to in this sample. Right-click the project in **Solution Explorer**, select **Add** > **New Folder**, then rename the folder to **Views**.

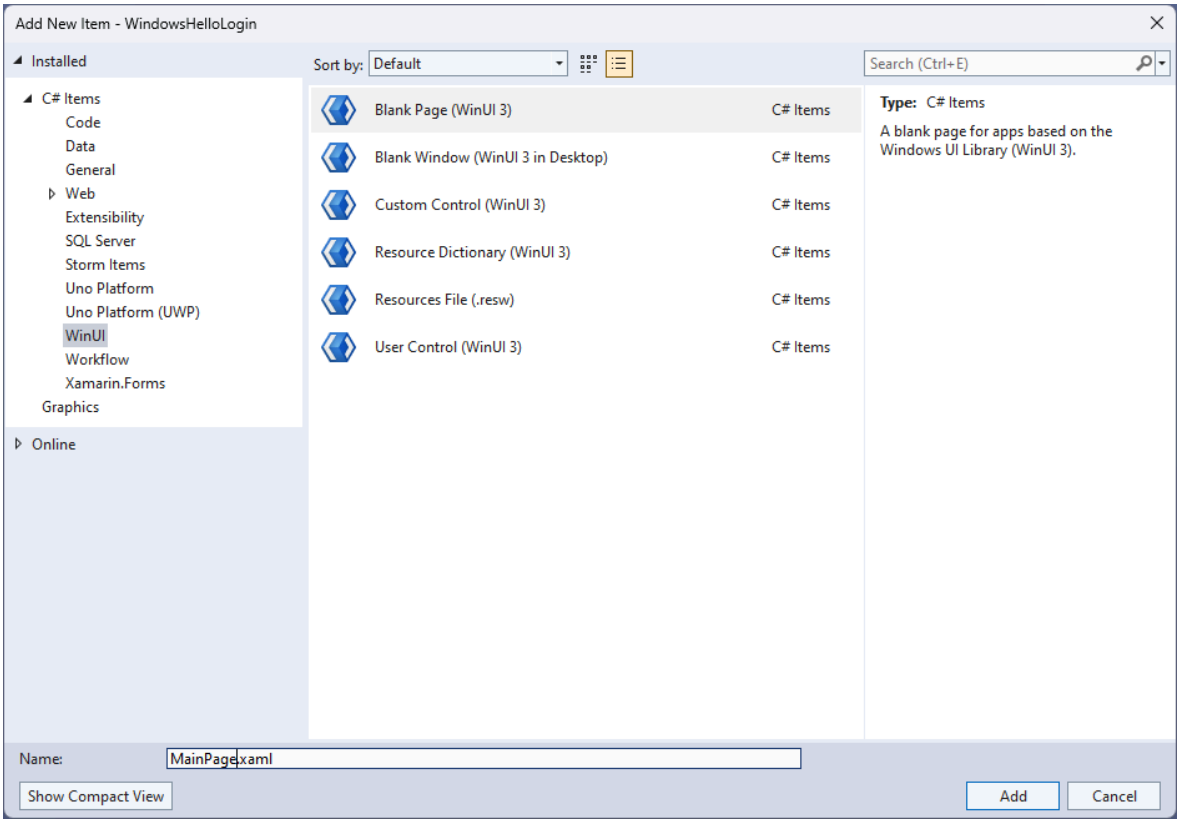


- Open MainWindow.xaml and replace the `Window` contents with an empty `StackPanel` or `Grid` control. We will be implementing page navigation and navigating to a new page when the **MainWindow** is loaded, so we don't need any content in the **MainWindow**.

- Add a `Title` property to **MainWindow** in the XAML. The attribute should look like this: `Title="Windows Hello Login"`.

- Remove the myButton_Click event handler from MainWindow.xaml.cs to avoid any compilation errors. This event handler is not needed for this sample.

- Right-click the new **Views** folder, select **Add** > **New Item** and select the **Blank Page** template. Name this page "MainPage.xaml".



- Open the App.xaml.cs file and update the **OnLaunched** handler to implement page navigation for the app. You'll also need to add a **RootFrame_NavigationFailed** handler method to deal with any errors that occur while loading pages.

```cs
protected override void
OnLaunched(Microsoft.UI.Xaml.LaunchActivatedEventArgs args)
{
    m_window = new MainWindow();
    var rootFrame = new Frame();
    rootFrame.NavigationFailed += RootFrame_NavigationFailed;
    rootFrame.Navigate(typeof(MainPage), args);
    m_window.Content = rootFrame;
    m_window.Activate();
}

private void RootFrame_NavigationFailed(object sender,
NavigationFailedEventArgs e)
{
    throw new Exception($"Error loading page
{e.SourcePageType.FullName}");
}
```

- You'll also need to add four using statements to the top of the App.xaml.cs file to resolve compilation errors in the code.

cs

```
using Microsoft.UI.Xaml.Controls;
using Microsoft.UI.Xaml.Navigation;
using System;
using WindowsHelloLogin.Views;
```

- Right-click the new **Views** folder, select **Add** > **New Item** and select the **Blank Page** template. Name this page "Login.xaml".
- To define the user interface for the new login page, add the following XAML. This XAML defines a `StackPanel` to align the following children:
  - A `TextBlock` that will contain a title.
  - A `TextBlock` for error messages.
  - A `TextBox` for the username to be input.
  - A `Button` to navigate to a register page.
  - A `TextBlock` to contain the status of Windows Hello.
  - A `TextBlock` to explain the Login page, as there is no backend or configured users yet.

XML

```
<Grid>
  <StackPanel>
    <TextBlock Text="Login" FontSize="36" Margin="4"
TextAlignment="Center"/>
    <TextBlock x:Name="ErrorMessage" Text="" FontSize="20"
Margin="4" Foreground="Red" TextAlignment="Center"/>
    <TextBlock Text="Enter your username below" Margin="0,0,0,20"
               TextWrapping="Wrap" Width="300"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>
    <TextBox x:Name="UsernameTextBox" Margin="4" Width="250"/>
    <Button x:Name="LoginButton" Content="Login"
Background="DodgerBlue" Foreground="White"
            Click="LoginButton_Click" Width="80"
HorizontalAlignment="Center" Margin="0,20"/>
    <TextBlock Text="Don't have an account?"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>
    <TextBlock x:Name="RegisterButtonTextBlock" Text="Register now"

PointerPressed="RegisterButtonTextBlock_OnPointerPressed"
               Foreground="DodgerBlue"
```

```
                TextAlignment="Center" VerticalAlignment="Center"
  FontSize="16"/>
      <Border x:Name="WindowsHelloStatus" Background="#22B14C"
              Margin="0,20" Height="100" >
        <TextBlock x:Name="WindowsHelloStatusText" Text="Windows Hello
  is ready to use!"
                   Margin="4" TextAlignment="Center"
  VerticalAlignment="Center" FontSize="20"/>
      </Border>
      <TextBlock x:Name="LoginExplanation" FontSize="24"
  TextAlignment="Center" TextWrapping="Wrap"
                 Text="Please Note: To demonstrate a login, validation
  will only occur using the default username 'sampleUsername'"/>
    </StackPanel>
  </Grid>
```

- A few methods need to be added to the code-behind file to get the solution building. Either press F7 or use the **Solution Explorer** to edit the Login.xaml.cs file. Add in the following two event methods to handle the **Login** and **Register** events. For now these methods will set the `ErrorMessage.Text` to an empty string. Be sure to include the following using statements. They will be needed for the next steps.

cs

```
using Microsoft.UI.Xaml;
using Microsoft.UI.Xaml.Controls;
using Microsoft.UI.Xaml.Input;
using Microsoft.UI.Xaml.Media;
using Microsoft.UI.Xaml.Navigation;
using System;

namespace WindowsHelloLogin.Views
{
    public sealed partial class Login : Page
    {
        public Login()
        {
            this.InitializeComponent();
        }
        private void LoginButton_Click(object sender, RoutedEventArgs
e)
        {
            ErrorMessage.Text = "";
        }
        private void RegisterButtonTextBlock_OnPointerPressed(object
sender, PointerRoutedEventArgs e)
        {
            ErrorMessage.Text = "";
        }
    }
}
```

- In order to render the **Login** page, edit the **MainPage** code to navigate to the **Login** page when the **MainPage** is loaded. Open the MainPage.xaml.cs file. In **Solution Explorer**, double-click on MainPage.xaml.cs. If you can't find this click the little arrow next to MainPage.xaml to show the code-behind file. Create a **Loaded** event handler method that will navigate to the **Login** page.

```cs
namespace WindowsHelloLogin.Views
{
    public sealed partial class MainPage : Page
    {
        public MainPage()
        {
            this.InitializeComponent();
            Loaded += MainPage_Loaded;
        }

        private void MainPage_Loaded(object sender, RoutedEventArgs e)
        {
            Frame.Navigate(typeof(Login));
        }
    }
}
```

- In the **Login** page, you need to handle the `OnNavigatedTo` event to validate if Windows Hello is available on the current machine. In Login.xaml.cs, implement the following code. You'll notice that the WindowsHelloHelper object indicates that there's an error. That's because we haven't created this helper class yet.

```cs
public sealed partial class Login : Page
{
    public Login()
    {
        this.InitializeComponent();
    }

    protected override async void OnNavigatedTo(NavigationEventArgs e)
    {
        // Check if Windows Hello is set up and available on this
machine
        if (await WindowsHelloHelper.WindowsHelloAvailableCheckAsync())
        {
        }
        else
        {
            // Windows Hello isn't set up, so inform the user
            WindowsHelloStatus.Background = new
```

```
SolidColorBrush(Windows.UI.Color.FromArgb(255, 50, 170, 207));
            WindowsHelloStatusText.Text = $"Windows Hello is not set
up!{Environment.NewLine}Please go to Windows Settings and set up a PIN
to use it.";
            LoginButton.IsEnabled = false;
        }
    }
}
```

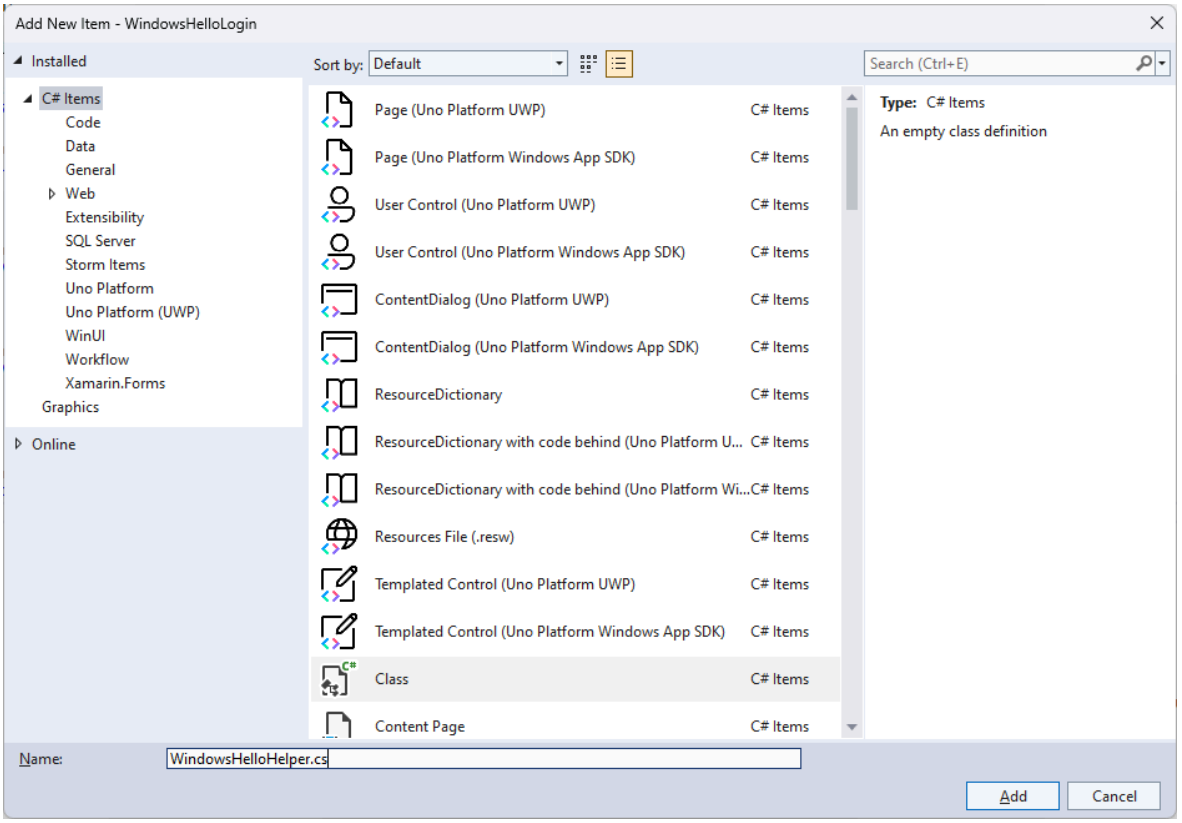
- To create the WindowsHelloHelper class, right-click the **WindowsHelloLogin** project and click **Add** > **New Folder**. Name this folder **Utils**.

- Right click the **Utils** folder and select **Add** > **Class**. Name this new class "WindowsHelloHelper.cs".



- Change the scope of the **WindowsHelloHelper** class to be `public static`, then add the following method that to inform the user if Windows Hello is ready to be used or not. You will need to add the required namespaces.

cs

```
using System;
using System.Diagnostics;
using System.Threading.Tasks;
using Windows.Security.Credentials;

namespace WindowsHelloLogin.Utils
{
    public static class WindowsHelloHelper
```

```
    {
        /// <summary>
        /// Checks to see if Windows Hello is ready to be used.
        ///
        /// Windows Hello has dependencies on:
        ///     1. Having a connected Microsoft Account
        ///     2. Having a Windows PIN set up for that account on the
local machine
        /// </summary>
        public static async Task<bool>
WindowsHelloAvailableCheckAsync()
        {
            bool keyCredentialAvailable = await
KeyCredentialManager.IsSupportedAsync();
            if (keyCredentialAvailable == false)
            {
                // Key credential is not enabled yet as user
                // needs to connect to a Microsoft Account and select a
PIN in the connecting flow.
                Debug.WriteLine("Windows Hello is not set up!\nPlease
go to Windows Settings and set up a PIN to use it.");
                return false;
            }

            return true;
        }
    }
}
```

- In Login.xaml.cs, add a reference to the `WindowsHelloLogin.Utils` namespace. This will resolve the error in the `OnNavigatedTo` method.

```cs
using WindowsHelloLogin.Utils;
```

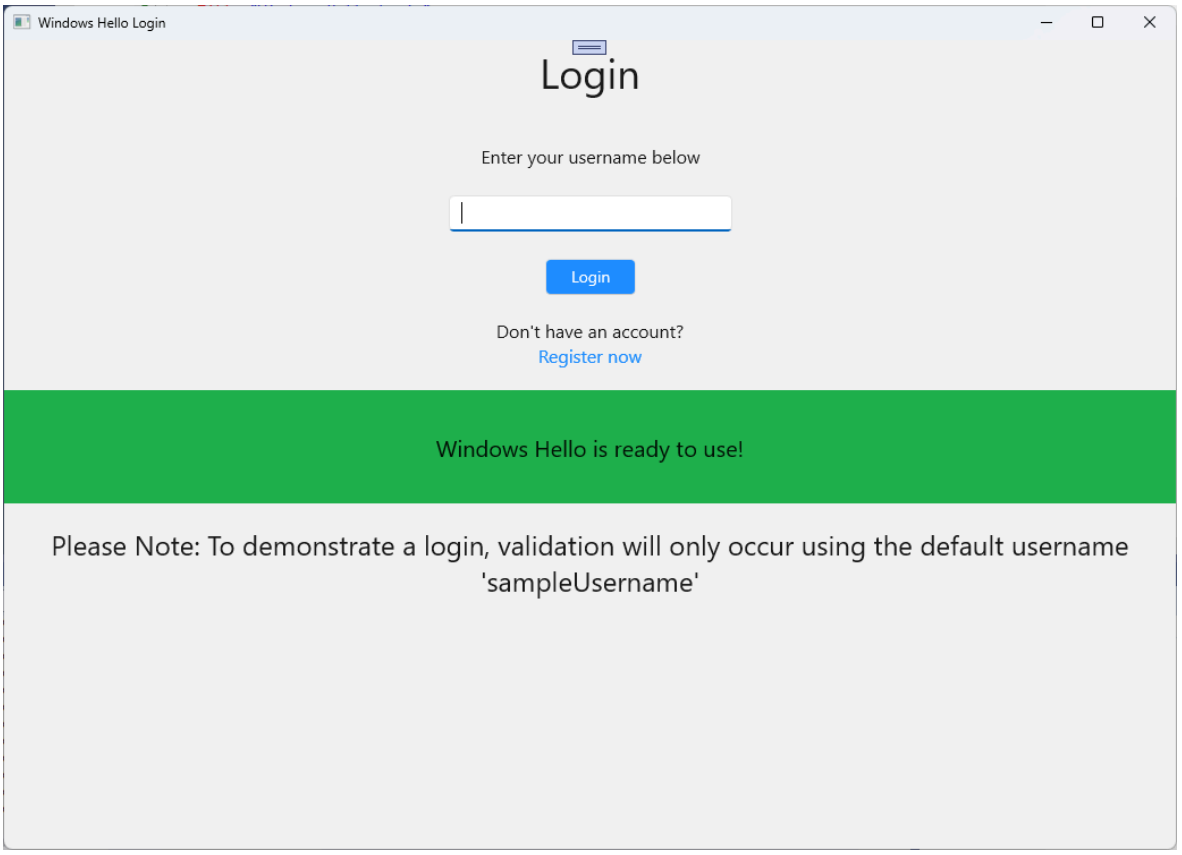
- Build and run the application. You will be navigated to the login page and the Windows Hello banner will indicate to you if Windows Hello is ready to be used. You should see either the green or blue banner indicating the Windows Hello status on your machine.



- The next thing you need to do is build the logic for signing in. Create a new folder in the project named "Models".
- In the **Models** folder, create a new class called "Account.cs". This class will act as your account model. As this is a sample project, it will only contain a username. Change the class scope to `public` and add the `Username` property.

cs

```cs
namespace WindowsHelloLogin.Models
{
    public class Account
    {
        public string Username { get; set; }
    }
}
```

- The app needs a way to handle accounts. For this hands on lab, as there is no server or database, a list of users are saved and loaded locally. Right-click the **Utils** folder and add a new class named "AccountHelper.cs". Change the class scope to be `public static`. The **AccountHelper** is a static class that contains all the necessary methods to save and load the list of accounts locally. Saving and loading works by using an **XmlSerializer**. You also need to remember the file that was saved and where you saved it.

cs

```
using System;
using System.Collections.Generic;
using System.IO;
using System.Text;
using System.Threading.Tasks;
using System.Xml.Serialization;
using Windows.Storage;
using WindowsHelloLogin.Models;

namespace WindowsHelloLogin.Utils
{
    public static class AccountHelper
    {
        // In the real world this would not be needed as there would be
a server implemented that would host a user account database.
        // For this tutorial we will just be storing accounts locally.
        private const string USER_ACCOUNT_LIST_FILE_NAME =
"accountlist.txt";
        private static string _accountListPath =
Path.Combine(ApplicationData.Current.LocalFolder.Path,
USER_ACCOUNT_LIST_FILE_NAME);
        public static List<Account> AccountList = [];

        /// <summary>
        /// Create and save a useraccount list file. (Updating the old
one)
        /// </summary>
        private static async void SaveAccountListAsync()
        {
            string accountsXml = SerializeAccountListToXml();

            if (File.Exists(_accountListPath))
            {
                StorageFile accountsFile = await
StorageFile.GetFileFromPathAsync(_accountListPath);
                await FileIO.WriteTextAsync(accountsFile, accountsXml);
            }
            else
            {
                StorageFile accountsFile = await
ApplicationData.Current.LocalFolder.CreateFileAsync(USER_ACCOUNT_LIST_F
ILE_NAME);
                await FileIO.WriteTextAsync(accountsFile, accountsXml);
            }
        }

        /// <summary>
        /// Gets the useraccount list file and deserializes it from XML
to a list of useraccount objects.
        /// </summary>
        /// <returns>List of useraccount objects</returns>
        public static async Task<List<Account>> LoadAccountListAsync()
        {
            if (File.Exists(_accountListPath))
```

```
            {
                StorageFile accountsFile = await
StorageFile.GetFileFromPathAsync(_accountListPath);

                string accountsXml = await
FileIO.ReadTextAsync(accountsFile);
                DeserializeXmlToAccountList(accountsXml);
            }

            return AccountList;
        }

        /// <summary>
        /// Uses the local list of accounts and returns an XML
formatted string representing the list
        /// </summary>
        /// <returns>XML formatted list of accounts</returns>
        public static string SerializeAccountListToXml()
        {
            var xmlizer = new XmlSerializer(typeof(List<Account>));
            var writer = new StringWriter();
            xmlizer.Serialize(writer, AccountList);

            return writer.ToString();
        }

        /// <summary>
        /// Takes an XML formatted string representing a list of
accounts and returns a list object of accounts
        /// </summary>
        /// <param name="listAsXml">XML formatted list of
accounts</param>
        /// <returns>List object of accounts</returns>
        public static List<Account> DeserializeXmlToAccountList(string
listAsXml)
        {
            var xmlizer = new XmlSerializer(typeof(List<Account>));
            TextReader textreader = new StreamReader(new
MemoryStream(Encoding.UTF8.GetBytes(listAsXml)));

            return AccountList = (xmlizer.Deserialize(textreader)) as
List<Account>;
        }
    }
}
```

- Next, implement a way to add and remove an account from the local list of accounts. These actions will each save the list. The final method that you'll need for this hands-on lab is a validation method. As there is no authorization server or database of users, this will validate against a single user which is hard-coded. These methods should be added to the **AccountHelper** class.

cs

```cs
public static Account AddAccount(string username)
{
    // Create a new account with the username
    var account = new Account() { Username = username };
    // Add it to the local list of accounts
    AccountList.Add(account);
    // SaveAccountList and return the account
    SaveAccountListAsync();
    return account;
}

public static void RemoveAccount(Account account)
{
    // Remove the account from the accounts list
    AccountList.Remove(account);
    // Re save the updated list
    SaveAccountListAsync();
}

public static bool ValidateAccountCredentials(string username)
{
    // In the real world, this method would call the server to
authenticate that the account exists and is valid.
    // However, for this tutorial, we'll just have an existing sample
user that's named "sampleUsername".
    // If the username is null or does not match "sampleUsername"
validation will fail.
    // In this case, the user should register a new Windows Hello user.

    if (string.IsNullOrEmpty(username))
    {
        return false;
    }

    if (!string.Equals(username, "sampleUsername"))
    {
        return false;
    }

    return true;
}
```

- The next thing you need to do is handle a sign in request from the user. In Login.xaml.cs, create a new private variable that will hold the current account logging in. Then add a new method named **SignInWindowsHelloAsync**. This will validate the account credentials using the **AccountHelper.ValidateAccountCredentials** method. This method will return a **Boolean** value if the entered user name is the same as the hard coded string value

you configured in the previous step. The hard-coded value for this sample is "sampleUsername".

cs

```
using WindowsHelloLogin.Models;
using WindowsHelloLogin.Utils;
using System.Diagnostics;
using System.Threading.Tasks;

namespace WindowsHelloLogin.Views
{
    public sealed partial class Login : Page
    {
        private Account _account;

        public Login()
        {
            this.InitializeComponent();
        }

        protected override async void OnNavigatedTo(NavigationEventArgs
e)
        {
            // Check if Windows Hello is set up and available on this
machine
            if (await
WindowsHelloHelper.WindowsHelloAvailableCheckAsync())
            {
            }
            else
            {
                // Windows Hello is not set up, so inform the user
                WindowsHelloStatus.Background = new
SolidColorBrush(Windows.UI.Color.FromArgb(255, 50, 170, 207));
                WindowsHelloStatusText.Text = "Windows Hello is not set
up!\nPlease go to Windows Settings and set up a PIN to use it.";
                LoginButton.IsEnabled = false;
            }
        }

        private async void LoginButton_Click(object sender,
RoutedEventArgs e)
        {
            ErrorMessage.Text = "";
            await SignInWindowsHelloAsync();
        }

        private void RegisterButtonTextBlock_OnPointerPressed(object
sender, PointerRoutedEventArgs e)
        {
            ErrorMessage.Text = "";
        }
```

```
        private async Task SignInWindowsHelloAsync()
        {
            if
(AccountHelper.ValidateAccountCredentials(UsernameTextBox.Text))
            {
                // Create and add a new local account
                _account =
AccountHelper.AddAccount(UsernameTextBox.Text);
                Debug.WriteLine("Successfully signed in with
traditional credentials and created local account instance!");

                //if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(UsernameTextBox.Text))
                //{
                //    Debug.WriteLine("Successfully signed in with
Windows Hello!");
                //}
            }
            else
            {
                ErrorMessage.Text = "Invalid Credentials";
            }
        }
    }
}
```

- You may have noticed the commented code that was referencing a method in **WindowsHelloHelper**. In WindowsHelloHelper.cs, add a new method named **CreateWindowsHelloKeyAsync**. This method uses the Windows Hello API in the KeyCredentialManager. Calling RequestCreateAsync will create a Windows Hello key that is specific to the *accountId* and the local machine. Please note the comments in the switch statement if you are interested in implementing this in a real world scenario.

cs

```
/// <summary>
/// Creates a Windows Hello key on the machine using the account ID
provided.
/// </summary>
/// <param name="accountId">The account ID associated with the account
that we are enrolling into Windows Hello</param>
/// <returns>Boolean indicating if creating the Windows Hello key
succeeded</returns>
public static async Task<bool> CreateWindowsHelloKeyAsync(string
accountId)
{
    KeyCredentialRetrievalResult keyCreationResult = await
KeyCredentialManager.RequestCreateAsync(accountId,
KeyCredentialCreationOption.ReplaceExisting);
```

```
    switch (keyCreationResult.Status)
    {
        case KeyCredentialStatus.Success:
            Debug.WriteLine("Successfully created key");

            // In the real world, authentication would take place on a
server.
            // So, every time a user migrates or creates a new Windows
Hello
            // account, details should be pushed to the server.
            // The details that would be pushed to the server include:
            // The public key, keyAttestation (if available),
            // certificate chain for attestation endorsement key (if
available),
            // status code of key attestation result:
keyAttestationIncluded or
            // keyAttestationCanBeRetrievedLater and
keyAttestationRetryType.
            // As this sample has no concept of a server, it will be
skipped for now.
            // For information on how to do this, refer to the second
sample.

            // For this sample, just return true
            return true;
        case KeyCredentialStatus.UserCanceled:
            Debug.WriteLine("User cancelled sign-in process.");
            break;
        case KeyCredentialStatus.NotFound:
            // User needs to set up Windows Hello
            Debug.WriteLine("Windows Hello is not set up!\nPlease go to
Windows Settings and set up a PIN to use it.");
            break;
        default:
            break;
    }

    return false;
}
```

- Now that you have created the **CreateWindowsHelloKeyAsync** method, return to the Login.xaml.cs file and uncomment the code inside the SignInWindowsHelloAsync method.

cs

```
private async void SignInWindowsHelloAsync()
{
    if (AccountHelper.ValidateAccountCredentials(UsernameTextBox.Text))
    {
        //Create and add a new local account
        _account = AccountHelper.AddAccount(UsernameTextBox.Text);
        Debug.WriteLine("Successfully signed in with traditional
```

```
credentials and created local account instance!");

        if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(UsernameTextBox.Text))
        {
            Debug.WriteLine("Successfully signed in with Windows
Hello!");
        }
    }
    else
    {
        ErrorMessage.Text = "Invalid Credentials";
    }
}
```

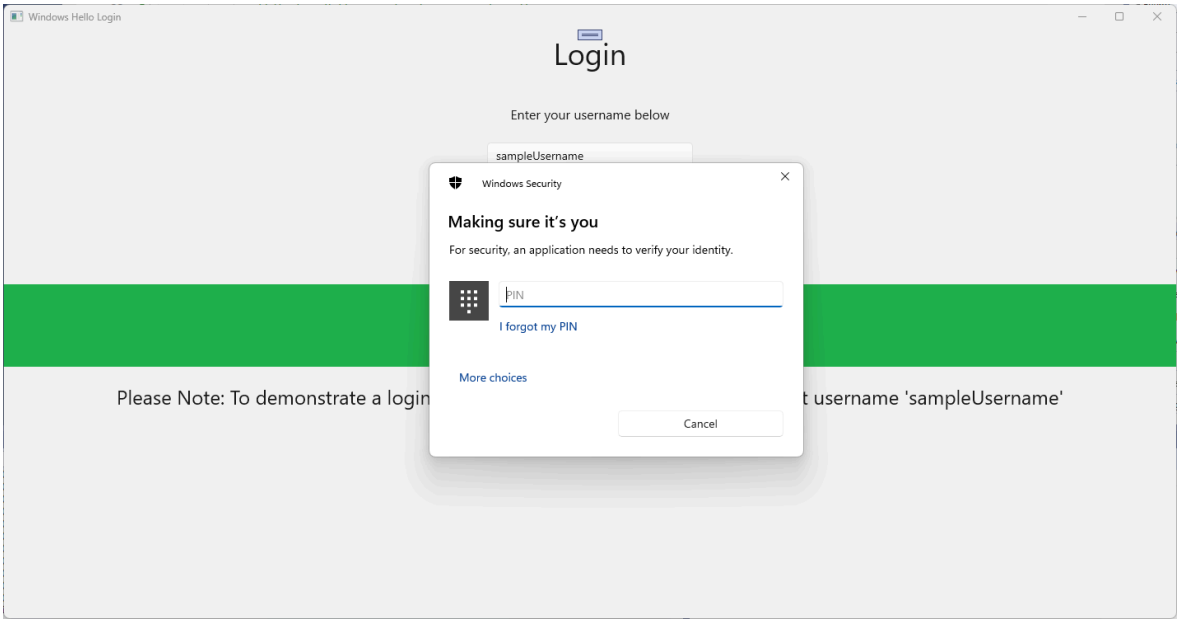
- Build and run the application. You will be taken to the Login page. Enter the user name as "sampleUsername" and click login. You will be prompted with a Windows Hello prompt asking you to enter your PIN. Upon entering your PIN correctly, the **CreateWindowsHelloKeyAsync** method will be able to create a Windows Hello key. Monitor the output windows to see if the messages indicating success are shown.



Exercise 2: Welcome and User Selection Pages

In this exercise, you will continue from the previous exercise. When a user successfully logs in, they should be taken to a welcome page where they can sign out or delete their account. As Windows Hello creates a key for every machine, a user selection screen can be created, which displays all users that have been signed in on that machine. A user can then select one of these accounts and go directly to the welcome screen without needed to re-enter a password as they have already authenticated to access the machine.

- In the **Views** folder add a new blank page named "Welcome.xaml". Add the following XAML to complete the user interface for the page. This will display a title, the logged in username, and two buttons. One of the buttons will navigate back to a user list (that you will create later), and the other button will handle forgetting this user.

XML

```
<Grid>
  <StackPanel>
    <TextBlock x:Name="Title" Text="Welcome" FontSize="40"
TextAlignment="Center"/>
    <TextBlock x:Name="UserNameText" FontSize="28"
TextAlignment="Center"/>

    <Button x:Name="BackToUserListButton" Content="Back to User List"
Click="Button_Restart_Click"
            HorizontalAlignment="Center" Margin="0,20"
Foreground="White" Background="DodgerBlue"/>

    <Button x:Name="ForgetButton" Content="Forget Me"
Click="Button_Forget_User_Click"
            Foreground="White"
            Background="Gray"
            HorizontalAlignment="Center"/>
  </StackPanel>
</Grid>
```

- In the Welcome.xaml.cs code-behind file, add a new private variable that will hold the account that is logged in. You will need to implement a method to override the `OnNavigateTo` event, this will store the account passed to the **Welcome** page. You will also need to implement the `Click` event for the two buttons defined in the XAML. You will need to add using statements for the `WindowsHelloLogin.Models` and `WindowsHelloLogin.Utils` namespaces.

cs

```
using WindowsHelloLogin.Models;
using WindowsHelloLogin.Utils;
using System.Diagnostics;

namespace WindowsHelloLogin.Views
{
    public sealed partial class Welcome : Page
    {
        private Account _activeAccount;

        public Welcome()
        {
```

```
            InitializeComponent();
        }

        protected override void OnNavigatedTo(NavigationEventArgs e)
        {
            _activeAccount = (Account)e.Parameter;
            if (_activeAccount != null)
            {
                UserNameText.Text = _activeAccount.Username;
            }
        }

        private void Button_Restart_Click(object sender,
RoutedEventArgs e)
        {
        }

        private void Button_Forget_User_Click(object sender,
RoutedEventArgs e)
        {
            // Remove the account from Windows Hello
            //
WindowsHelloHelper.RemoveWindowsHelloAccountAsync(_activeAccount);

            // Remove it from the local accounts list and re-save the
updated list
            AccountHelper.RemoveAccount(_activeAccount);

            Debug.WriteLine($"User {_activeAccount.Username}
deleted.");
        }
    }
}
```

- You may have noticed a line commented out in the `Button_Forget_User_Click` event handler. The account is being removed from your local list but currently there is no way to be removed from Windows Hello. You need to implement a new method in WindowsHelloHelper.cs that will handle removing a Windows Hello user. This method will use other Windows Hello APIs to open and delete the account. In the real world, when you delete an account the server or database should be notified so the user database remains valid. You will need a using statement referencing the `WindowsHelloLogin.Models` namespace.

cs

```
using WindowsHelloLogin.Models;

/// <summary>
/// Function to be called when user requests deleting their account.
/// Checks the KeyCredentialManager to see if there is a Windows Hello
/// account for the current user.
```

```
/// It then deletes the local key associated with the account.
/// </summary>
public static async void RemoveWindowsHelloAccountAsync(Account
account)
{
    // Open the account with Windows Hello
    KeyCredentialRetrievalResult keyOpenResult = await
KeyCredentialManager.OpenAsync(account.Username);

    if (keyOpenResult.Status == KeyCredentialStatus.Success)
    {
        // In the real world you would send key information to server
to unregister
        //for example, RemoveWindowsHelloAccountOnServer(account);
    }

    // Then delete the account from the machine's list of Windows Hello
accounts
    await KeyCredentialManager.DeleteAsync(account.Username);
}
```

- Back in Welcome.xaml.cs, uncomment the line that calls **RemoveWindowsHelloAccountAsync**.

cs

```
private void Button_Forget_User_Click(object sender, RoutedEventArgs e)
{
    // Remove it from Windows Hello
    WindowsHelloHelper.RemoveWindowsHelloAccountAsync(_activeAccount);

    // Remove it from the local accounts list and re-save the updated
list
    AccountHelper.RemoveAccount(_activeAccount);

    Debug.WriteLine($"User {_activeAccount.Username} deleted.");
}
```

- In the **SignInWindowsHelloAsync** method (in Login.xaml.cs), once the **CreateWindowsHelloKeyAsync** is successful, it should navigate to the **Welcome** page and pass the **Account**.

cs

```
private async void SignInWindowsHelloAsync()
{
    if (AccountHelper.ValidateAccountCredentials(UsernameTextBox.Text))
    {
        // Create and add a new local account
        _account = AccountHelper.AddAccount(UsernameTextBox.Text);
        Debug.WriteLine("Successfully signed in with traditional
```

```
credentials and created local account instance!");

        if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(UsernameTextBox.Text))
        {
            Debug.WriteLine("Successfully signed in with Windows
Hello!");
            Frame.Navigate(typeof(Welcome), _account);
        }
    }
    else
    {
        ErrorMessage.Text = "Invalid Credentials";
    }
}
```

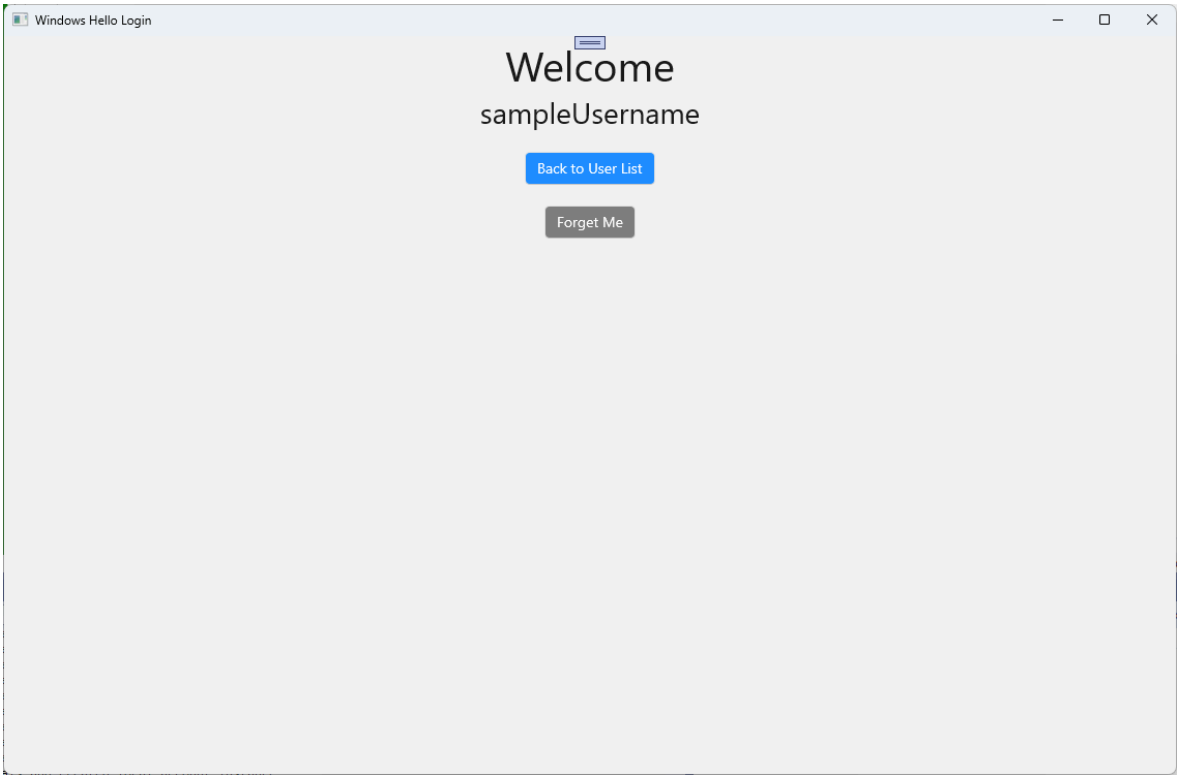
- Build and run the application. Login with "sampleUsername" and click **Login**. Enter your PIN and if successful you should be navigated to the **Welcome** screen. Try clicking **Forget User** and monitor Visual Studio's **Output** window to see if the user was deleted. Notice that when the user is deleted, you remain on the **Welcome** page. You'll need to create a user selection page to which the app can navigate.



- In the **Views** folder, create a new blank page named "UserSelection.xaml" and add the following XAML to define the user interface. This page will contain a ListView that displays all the users in the local accounts list, and a `Button` that will navigate to the **Login** page to allow the user to add another account.

```
XML
```

```
<Grid>
  <StackPanel>
    <TextBlock x:Name="Title" Text="Select a User" FontSize="36"
Margin="4" TextAlignment="Center" HorizontalAlignment="Center"/>

    <ListView x:Name="UserListView" Margin="4" MaxHeight="200"
MinWidth="250" Width="250" HorizontalAlignment="Center">
      <ListView.ItemTemplate>
        <DataTemplate>
          <Grid Background="DodgerBlue" Height="50" Width="250"
HorizontalAlignment="Stretch" VerticalAlignment="Stretch">
            <TextBlock Text="{Binding Username}"
HorizontalAlignment="Center" TextAlignment="Center"
VerticalAlignment="Center" Foreground="White"/>
          </Grid>
        </DataTemplate>
      </ListView.ItemTemplate>
    </ListView>

    <Button x:Name="AddUserButton" Content="+" FontSize="36" Width="60"
Click="AddUserButton_Click" HorizontalAlignment="Center"/>
  </StackPanel>
</Grid>
```

- In UserSelection.xaml.cs, implement the `Loaded` method that will navigate to the **Login** page if there are no accounts in the local list. Also implement the `SelectionChanged` event for the `ListView` and a `Click` event for the `Button`.

cs

```
using System.Diagnostics;
using WindowsHelloLogin.Models;
using WindowsHelloLogin.Utils;

namespace WindowsHelloLogin.Views
{
    public sealed partial class UserSelection : Page
    {
        public UserSelection()
        {
            InitializeComponent();
            Loaded += UserSelection_Loaded;
        }

        private void UserSelection_Loaded(object sender,
RoutedEventArgs e)
        {
            if (AccountHelper.AccountList.Count == 0)
            {
                // If there are no accounts, navigate to the Login page
                Frame.Navigate(typeof(Login));
```

```
            }

            UserListView.ItemsSource = AccountHelper.AccountList;
            UserListView.SelectionChanged += UserSelectionChanged;
        }

        /// <summary>
        /// Function called when an account is selected in the list of
accounts
        /// Navigates to the Login page and passes the chosen account
        /// </summary>
        private void UserSelectionChanged(object sender,
RoutedEventArgs e)
        {
            if (((ListView)sender).SelectedValue != null)
            {
                Account account = (Account)
((ListView)sender).SelectedValue;
                if (account != null)
                {
                    Debug.WriteLine($"Account {account.Username}
selected!");
                }
                Frame.Navigate(typeof(Login), account);
            }
        }

        /// <summary>
        /// Function called when the "+" button is clicked to add a new
user.
        /// Navigates to the Login page with nothing filled out
        /// </summary>
        private void AddUserButton_Click(object sender, RoutedEventArgs
e)
        {
            Frame.Navigate(typeof(Login));
        }
    }
}
```

- There are a few places in the app where you want to navigate to the **UserSelection** page. In MainPage.xaml.cs, you should navigate to the **UserSelection** page instead of the **Login** page. While you are in the loaded event in **MainPage**, you will need to load the accounts list so the **UserSelection** page can check if there are any accounts. This will require changing the `Loaded` method to be async and also adding a using statement for the `WindowsHelloLogin.Utils` namespace.

```
cs
```

```
using WindowsHelloLogin.Utils;

private async void MainPage_Loaded(object sender, RoutedEventArgs e)
{
    // Load the local account list before navigating to the
UserSelection page
    await AccountHelper.LoadAccountListAsync();
    Frame.Navigate(typeof(UserSelection));
}
```

- Next, the app will need navigate to the **UserSelection** page from the **Welcome** page. In both `Click` events, you should navigate back to the **UserSelection** page.

cs

```
private void Button_Restart_Click(object sender, RoutedEventArgs e)
{
    Frame.Navigate(typeof(UserSelection));
}

private void Button_Forget_User_Click(object sender, RoutedEventArgs e)
{
    // Remove it from Windows Hello
    WindowsHelloHelper.RemoveWindowsHelloAccountAsync(_activeAccount);

    // Remove it from the local accounts list and re-save the updated
list
    AccountHelper.RemoveAccount(_activeAccount);

    Debug.WriteLine($"User {_activeAccount.Username} deleted.");

    // Navigate back to UserSelection page.
    Frame.Navigate(typeof(UserSelection));
}
```

- In the **Login** page, you need code to log in to the account selected from the list in the **UserSelection** page. In the `OnNavigatedTo` event, store the account passed during navigation. Start by adding a new private variable that will identify if the account is an existing account. Then handle the `OnNavigatedTo` event.

cs

```
namespace WindowsHelloLogin.Views
{
    public sealed partial class Login : Page
    {
        private Account _account;
        private bool _isExistingAccount;
```

```
        public Login()
        {
            InitializeComponent();
        }

        /// <summary>
        /// Function called when this frame is navigated to.
        /// Checks to see if Windows Hello is available and if an
account was passed in.
        /// If an account was passed in set the "_isExistingAccount"
flag to true and set the _account.
        /// </summary>
        protected override async void OnNavigatedTo(NavigationEventArgs
e)
        {
            // Check Windows Hello is set up and available on this
machine
            if (await
WindowsHelloHelper.WindowsHelloAvailableCheckAsync())
            {
                if (e.Parameter != null)
                {
                    _isExistingAccount = true;
                    // Set the account to the existing account being
passed in
                    _account = (Account)e.Parameter;
                    UsernameTextBox.Text = _account.Username;
                    await SignInWindowsHelloAsync();
                }
            }
            else
            {
                // Windows Hello is not set up, so inform the user
                WindowsHelloStatus.Background = new
SolidColorBrush(Windows.UI.Color.FromArgb(255, 50, 170, 207));
                WindowsHelloStatusText.Text = $"Windows Hello is not
set up!{Environment.NewLine}Please go to Windows Settings and set up a
PIN to use it.";
                LoginButton.IsEnabled = false;
            }
        }
    }
}
```

- The **SignInWindowsHelloAsync** method will need to be updated to sign in to the selected account. The **WindowsHelloHelper** will need another method to open the account with Windows Hello, as the account already has an account key created for it. Implement the new method in WindowsHelloHelper.cs to sign in an existing user with Windows Hello. For information on each part of the code, please read through the code comments.

```
cs
```

```
/// <summary>
/// Attempts to sign a message using the account key on the system for
the accountId passed.
/// </summary>
/// <returns>Boolean representing if creating the Windows Hello
authentication message succeeded</returns>
public static async Task<bool>
GetWindowsHelloAuthenticationMessageAsync(Account account)
{
    KeyCredentialRetrievalResult openKeyResult = await
KeyCredentialManager.OpenAsync(account.Username);
    // Calling OpenAsync will allow the user access to what is
available in the app and will not require user credentials again.
    // If you wanted to force the user to sign in again you can use the
following:
    // var consentResult = await
Windows.Security.Credentials.UI.UserConsentVerifier.RequestVerification
Async(account.Username);
    // This will ask for the either the password of the currently
signed in Microsoft Account or the PIN used for Windows Hello.

    if (openKeyResult.Status == KeyCredentialStatus.Success)
    {
        // If OpenAsync has succeeded, the next thing to think about is
whether the client application requires access to backend services.
        // If it does here you would request a challenge from the
server. The client would sign this challenge and the server
        // would check the signed challenge. If it is correct, it would
allow the user access to the backend.
        // You would likely make a new method called RequestSignAsync
to handle all this.
        // For example, RequestSignAsync(openKeyResult);
        // Refer to the second Windows Hello sample for information on
how to do this.

        // For this sample, there is not concept of a server
implemented so just return true.
        return true;
    }
    else if (openKeyResult.Status == KeyCredentialStatus.NotFound)
    {
        // If the account is not found at this stage. It could be one
of two errors.
        // 1. Windows Hello has been disabled
        // 2. Windows Hello has been disabled and re-enabled cause the
Windows Hello Key to change.
        // Calling CreateWindowsHelloKeyAsync and passing through the
account will attempt to replace the existing Windows Hello Key for that
account.
        // If the error really is that Windows Hello is disabled then
the CreateWindowsHelloKeyAsync method will output that error.
        if (await CreateWindowsHelloKeyAsync(account.Username))
        {
            // If the Hello Key was again successfully created, Windows
```

```
Hello has just been reset.
            // Now that the Hello Key has been reset for the account
retry sign in.
            return await
GetWindowsHelloAuthenticationMessageAsync(account);
        }
    }

    // Can't use Windows Hello right now, try again later
    return false;
}
```

- Update the **SignInWindowsHelloAsync** method in Login.xaml.cs to handle the existing account. This will use the new method in the WindowsHelloHelper.cs. If successful the account will be signed in and the user navigated to the **Welcome** page.

cs

```
private async Task SignInWindowsHelloAsync()
{
    if (_isExistingAccount)
    {
        if (await
WindowsHelloHelper.GetWindowsHelloAuthenticationMessageAsync(_account))
        {
            Frame.Navigate(typeof(Welcome), _account);
        }
    }
    else if
(AccountHelper.ValidateAccountCredentials(UsernameTextBox.Text))
    {
        //Create and add a new local account
        _account = AccountHelper.AddAccount(UsernameTextBox.Text);
        Debug.WriteLine("Successfully signed in with traditional
credentials and created local account instance!");

        if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(UsernameTextBox.Text))
        {
            Debug.WriteLine("Successfully signed in with Windows
Hello!");
            Frame.Navigate(typeof(Welcome), _account);
        }
    }
    else
    {
        ErrorMessage.Text = "Invalid Credentials";
    }
}
```

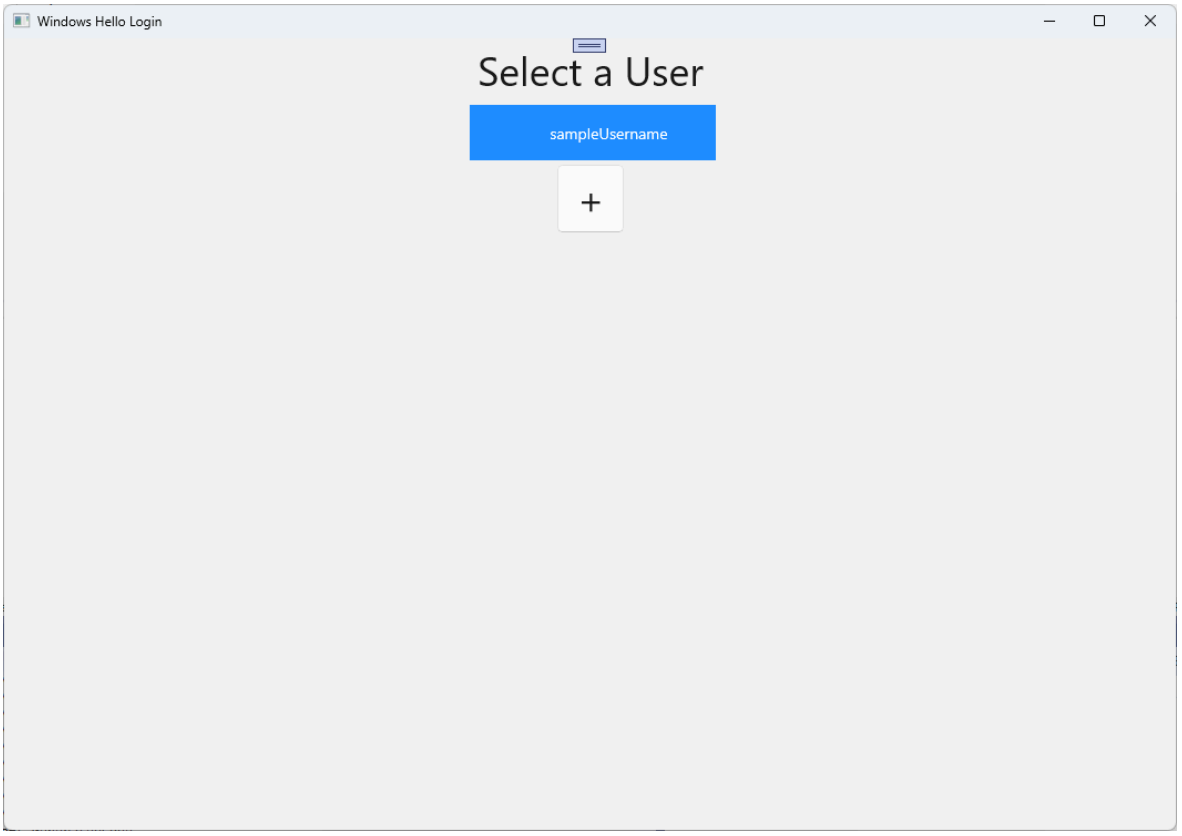
- Build and run the application. Login with "sampleUsername". Type in your PIN and if successful you will be navigated to the **Welcome** page. Click back to user list. You should now see a user in the list. If you click on this, WindowsHello enables you to sign back in without having to re-enter any passwords etc.



Exercise 3: Registering a new Windows Hello user

In this exercise, you create a new page that can create a new account with Windows Hello. This works similarly to how the **Login** page works. The **Login** page is implemented for an existing user that is migrating to use Windows Hello. A **WindowsHelloRegister** page will create Windows Hello registration for a new user.

- In the **Views** folder, create a new blank page named "WindowsHelloRegister.xaml". In the XAML add in the following to setup the user interface. The interface on this page is similar to the **Login** page.

XML

```
<Grid>
  <StackPanel>
    <TextBlock x:Name="Title" Text="Register New Windows Hello User"
FontSize="24" Margin="4" TextAlignment="Center"/>

    <TextBlock x:Name="ErrorMessage" Text="" FontSize="20" Margin="4"
```

```
Foreground="Red" TextAlignment="Center"/>

    <TextBlock Text="Enter your new username below" Margin="0,0,0,20"
               TextWrapping="Wrap" Width="300"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>

    <TextBox x:Name="UsernameTextBox" Margin="4" Width="250"/>

    <Button x:Name="RegisterButton" Content="Register"
Background="DodgerBlue" Foreground="White"
            Click="RegisterButton_Click_Async" Width="80"
HorizontalAlignment="Center" Margin="0,20"/>

    <Border x:Name="WindowsHelloStatus" Background="#22B14C" Margin="4"
Height="100">
      <TextBlock x:Name="WindowsHelloStatusText" Text="Windows Hello is
ready to use!" FontSize="20"
                 Margin="4" TextAlignment="Center"
VerticalAlignment="Center"/>
    </Border>
  </StackPanel>
</Grid>
```

- In the WindowsHelloRegister.xaml.cs code-behind file, implement a private `Account` variable and a `Click` event for the register button. This will add a new local account and create a Windows Hello key.

cs

```
using Microsoft.UI.Xaml.Controls;
using Microsoft.UI.Xaml;
using WindowsHelloLogin.Models;
using WindowsHelloLogin.Utils;

namespace WindowsHelloLogin.Views
{
    public sealed partial class WindowsHelloRegister : Page
    {
        private Account _account;

        public WindowsHelloRegister()
        {
            InitializeComponent();
        }

        private async void RegisterButton_Click_Async(object sender,
RoutedEventArgs e)
        {
            ErrorMessage.Text = "";

            // In the real world, you would validate the entered
```

```
credentials and information before
            // allowing a user to register a new account.
            // For this sample, we'll skip that step and just register
an account if the username is not null.

            if (!string.IsNullOrEmpty(UsernameTextBox.Text))
            {
                // Register a new account
                _account =
AccountHelper.AddAccount(UsernameTextBox.Text);
                // Register new account with Windows Hello
                await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(_account.Username);
                // Navigate to the Welcome page.
                Frame.Navigate(typeof(Welcome), _account);
            }
            else
            {
                ErrorMessage.Text = "Please enter a username";
            }
        }
    }
}
```

- You need to navigate to this page from the **Login** page when register is clicked.

cs

```
private void RegisterButtonTextBlock_OnPointerPressed(object sender,
PointerRoutedEventArgs e)
{
    ErrorMessage.Text = "";
    Frame.Navigate(typeof(WindowsHelloRegister));
}
```

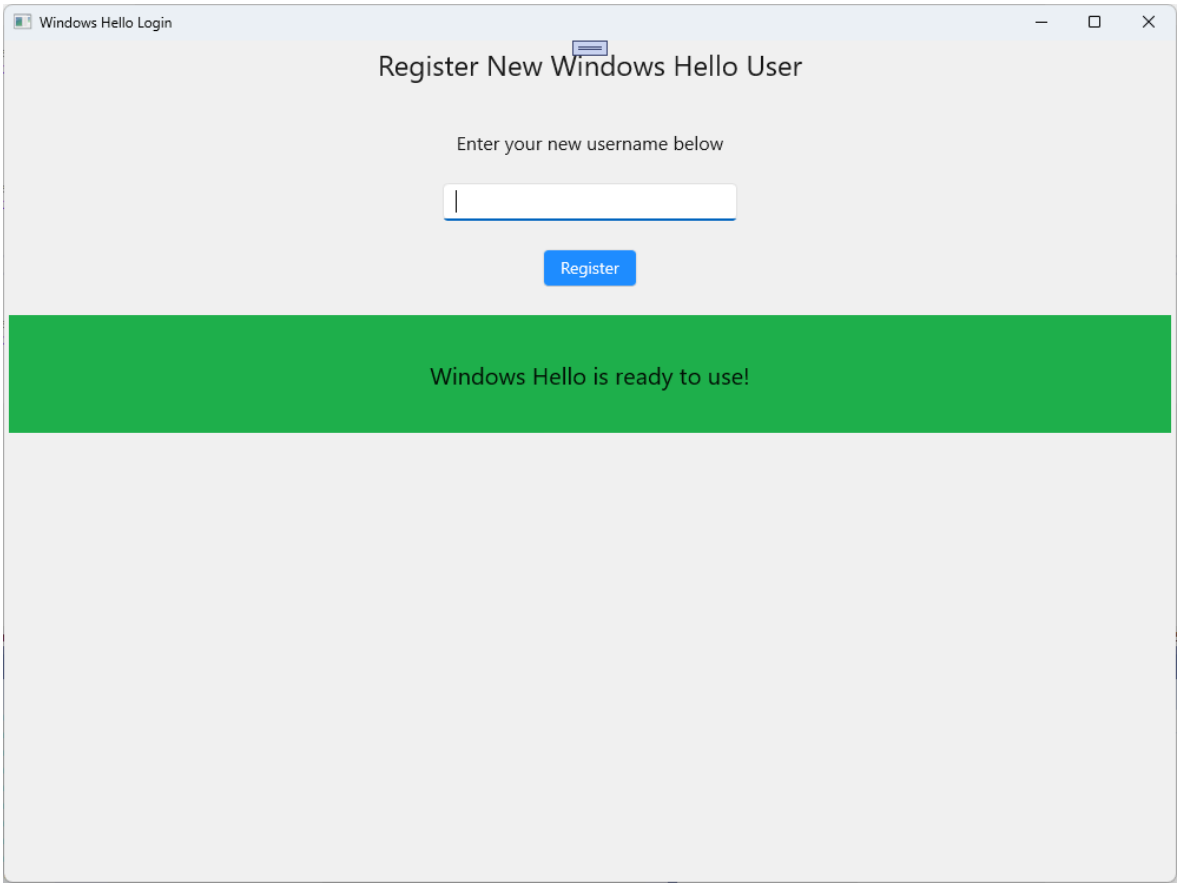
- Build and run the application. Try to register a new user. Then return to the user list and validate that you can select that user and login.



In this lab, you have learned the essential skills needed to use the new Windows Hello API to authenticate existing users and create accounts for new users. With this new knowledge, you can start removing the need for users to remember passwords for your application, yet remain confident that your applications remain protected by user authentication. Windows uses Windows Hello's new authentication technology to support its biometrics login options.

Create a Windows Hello login service

Article • 07/11/2024

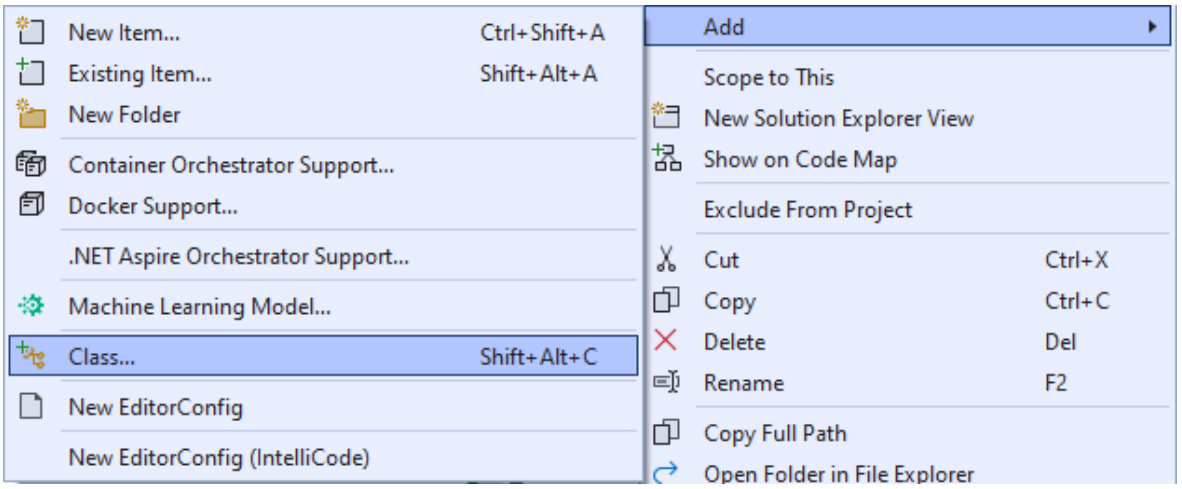
This is the second part of a complete walkthrough on how to use Windows Hello as an alternative to traditional username and password authentication systems in packaged Windows apps. This article picks up where Part 1, Windows Hello login app, left off and extends the functionality to demonstrate how you can integrate Windows Hello into your existing application.

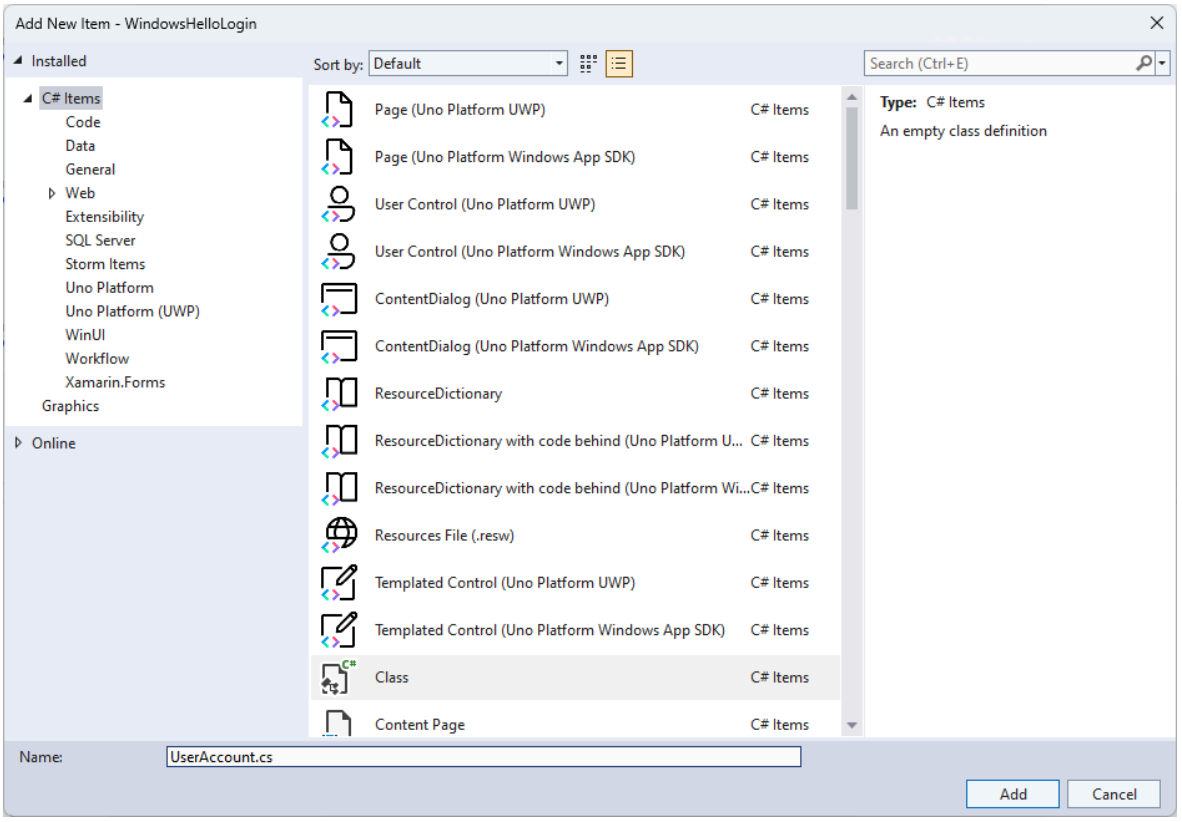
In order to build this project, you'll need some experience with C#, and XAML. You'll also need to be using Visual Studio 2022 on a Windows 10 or Windows 11 machine. See Start developing Windows apps for complete instructions on setting up your development environment.

Exercise 1: Server Side Logic

In this exercise, you start with the Windows Hello application built in the first lab and create a local mock server and database. This hands on lab is designed to teach how Windows Hello can be integrated into an existing system. By using a mock server and mock database, a lot of unrelated setup is eliminated. In your own applications, you will need to replace the mock objects with the real services and databases.

- To begin, open up the **WindowsHelloLogin** solution from the first Windows Hello Hands On Lab.
- You will start by implementing the mock server and mock database. Create a new folder named "AuthService". In Solution Explorer, right-click the **WindowsHelloLogin** project and select **Add** > **New Folder**.
- Create **UserAccount** and **WindowsHelloDevices** classes that will act as models for data to be saved in the mock database. The **UserAccount** will be similar to the user model implemented on a traditional authentication server. Right-click the **AuthService** folder and add a new class named "UserAccount".





- Change the class scope to be public and add the following public properties for the **UserAccount** class. You will need to add a using statement for the `System.ComponentModel.DataAnnotations` namespace.

cs

```cs
using System;
using System.ComponentModel.DataAnnotations;

namespace WindowsHelloLogin.AuthService
{
    public class UserAccount
    {
        [Key, Required]
        public Guid UserId { get; set; }
        [Required]
        public string Username { get; set; }
```

```
        public string Password { get; set; }
        // public List<WindowsHelloDevice> WindowsHelloDevices = new();
    }
}
```

You may have noticed the commented out list of **WindowsHelloDevices**. This is a modification you will need to make to an existing user model in your current implementation. The list of **WindowsHelloDevices** will contain a *deviceID*, the public key made from Windows Hello, and a KeyCredentialAttestationResult. For this exercise, you will need to implement the *keyAttestationResult* as they are only provided by Windows Hello on devices that have a TPM (Trusted Platform Modules) chip. The **KeyCredentialAttestationResult** is a combination of multiple properties and would need to be split in order to save and load them with a database.

- Create a new class in the **AuthService** folder called "WindowsHelloDevice.cs". This is the model for the Windows Hello devices as discussed above. Change the class scope to be public and add the following properties.

```cs
using System;

namespace WindowsHelloLogin.AuthService
{
    public class WindowsHelloDevice
    {
        // These are the new variables that will need to be added to
the existing UserAccount in the Database
        // The DeviceName is used to support multiple devices for the
one user.
        // This way the correct public key is easier to find as a new
public key is made for each device.
        // The KeyAttestationResult is only used if the User device has
a TPM (Trusted Platform Module) chip,
        // in most cases it will not. So will be left out for this
hands on lab.
        public Guid DeviceId { get; set; }
        public byte[] PublicKey { get; set; }
        // public KeyCredentialAttestationResult KeyAttestationResult {
get; set; }
    }
}
```

- Return to UserAccount.cs and uncomment the list of Windows Hello devices.

```cs
```

```
using System.Collections.Generic;

namespace WindowsHelloLogin.AuthService
{
    public class UserAccount
    {
        [Key, Required]
        public Guid UserId { get; set; }
        [Required]
        public string Username { get; set; }
        public string Password { get; set; }
        public List<WindowsHelloDevice> WindowsHelloDevices = new();
    }
}
```

- With the model for the **UserAccount** and the **WindowsHelloDevice** created, you need to create another new class in the **AuthService** folder that will act as the mock database, as this is a mock database from where you will be saving and loading a list of user accounts locally. In the real world, this would be your database implementation. Create a new class in the **AuthService** folder named "MockStore.cs". Change the class scope to public.

- As the mock store will save and load a list of user accounts locally, you can implement the logic to save and load that list using an **XmlSerializer**. You will also need to remember the filename and save location. In MockStore.cs implement the following:

cs

```
using System.Collections.Generic;
using System;
using System.IO;
using System.Linq;
using System.Text;
using System.Threading.Tasks;
using System.Xml.Serialization;
using Windows.Storage;

namespace WindowsHelloLogin.AuthService
{
    public class MockStore
    {
        private const string USER_ACCOUNT_LIST_FILE_NAME =
"userAccountsList.txt";
        // This cannot be a const because the LocalFolder is accessed
at runtime
        private string _userAccountListPath = Path.Combine(
            ApplicationData.Current.LocalFolder.Path,
USER_ACCOUNT_LIST_FILE_NAME);
```

```
        private List<UserAccount> _mockDatabaseUserAccountsList;

#region Save and Load Helpers
        /// <summary>
        /// Create and save a useraccount list file. (Replacing the old
one)
        /// </summary>
        private async Task SaveAccountListAsync()
        {
            string accountsXml = SerializeAccountListToXml();

            if (File.Exists(_userAccountListPath))
            {
                StorageFile accountsFile = await
StorageFile.GetFileFromPathAsync(_userAccountListPath);
                await FileIO.WriteTextAsync(accountsFile, accountsXml);
            }
            else
            {
                StorageFile accountsFile = await
ApplicationData.Current.LocalFolder.CreateFileAsync(USER_ACCOUNT_LIST_F
ILE_NAME);
                await FileIO.WriteTextAsync(accountsFile, accountsXml);
            }
        }

        /// <summary>
        /// Gets the useraccount list file and deserializes it from XML
to a list of useraccount objects.
        /// </summary>
        /// <returns>List of useraccount objects</returns>
        private async Task LoadAccountListAsync()
        {
            if (File.Exists(_userAccountListPath))
            {
                StorageFile accountsFile = await
StorageFile.GetFileFromPathAsync(_userAccountListPath);

                string accountsXml = await
FileIO.ReadTextAsync(accountsFile);
                DeserializeXmlToAccountList(accountsXml);
            }

            // If the UserAccountList does not contain the sampleUser
Initialize the sample users
            // This is only needed as it in a Hand on Lab to
demonstrate a user being migrated.
            // In the real world, user accounts would just be in a
database.
            if (!_mockDatabaseUserAccountsList.Any(f =>
f.Username.Equals("sampleUsername")))
            {
                //If the list is empty, call InitializeSampleAccounts
and return the list
                //await InitializeSampleUserAccountsAsync();
```

```
            }
        }

        /// <summary>
        /// Uses the local list of accounts and returns an XML
formatted string representing the list
        /// </summary>
        /// <returns>XML formatted list of accounts</returns>
        private string SerializeAccountListToXml()
        {
            var xmlizer = new XmlSerializer(typeof(List<UserAccount>));
            var writer = new StringWriter();
            xmlizer.Serialize(writer, _mockDatabaseUserAccountsList);
            return writer.ToString();
        }

        /// <summary>
        /// Takes an XML formatted string representing a list of
accounts and returns a list object of accounts
        /// </summary>
        /// <param name="listAsXml">XML formatted list of
accounts</param>
        /// <returns>List object of accounts</returns>
        private List<UserAccount> DeserializeXmlToAccountList(string
listAsXml)
        {
            var xmlizer = new XmlSerializer(typeof(List<UserAccount>));
            TextReader textreader = new StreamReader(new
MemoryStream(Encoding.UTF8.GetBytes(listAsXml)));
            return _mockDatabaseUserAccountsList =
(xmlizer.Deserialize(textreader)) as List<UserAccount>;
        }
#endregion
    }
}
```

- In the **LoadAccountListAsync** method, you may have noticed that an **InitializeSampleUserAccountsAsync** method was commented out. You will need to create this method in the MockStore.cs. This method will populate the user accounts list so that a login can take place. In the real world, the user database would already be populated. In this step, you will also be creating a constructor that will initialize the user list and call **LoadAccountListAsync**.

cs

```
namespace WindowsHelloLogin.AuthService
{
    public class MockStore
    {
        private const string USER_ACCOUNT_LIST_FILE_NAME =
"userAccountsList.txt";
        // This cannot be a const because the LocalFolder is accessed
```

```
at runtime
        private string _userAccountListPath = Path.Combine(
            ApplicationData.Current.LocalFolder.Path,
USER_ACCOUNT_LIST_FILE_NAME);
        private List<UserAccount> _mockDatabaseUserAccountsList;

        public MockStore()
        {
            _mockDatabaseUserAccountsList = new List<UserAccount>();
            _ = LoadAccountListAsync();
        }

        private async Task InitializeSampleUserAccountsAsync()
        {
            // Create a sample Traditional User Account that only has a
Username and Password
            // This will be used initially to demonstrate how to
migrate to use Windows Hello

            var sampleUserAccount = new UserAccount()
            {
                UserId = Guid.NewGuid(),
                Username = "sampleUsername",
                Password = "samplePassword",
            };

            // Add the sampleUserAccount to the _mockDatabase
            _mockDatabaseUserAccountsList.Add(sampleUserAccount);
            await SaveAccountListAsync();
        }
    }
}
```

- Now that the **InitializeSampleUserAccountsAsync** method exists uncomment the method call in the **LoadAccountListAsync** method.

cs

```
private async Task LoadAccountListAsync()
{
    if (File.Exists(_userAccountListPath))
    {
        StorageFile accountsFile = await
StorageFile.GetFileFromPathAsync(_userAccountListPath);

        string accountsXml = await FileIO.ReadTextAsync(accountsFile);
        DeserializeXmlToAccountList(accountsXml);
    }

    // If the UserAccountList does not contain the sampleUser
Initialize the sample users
    // This is only needed as it in a Hand on Lab to demonstrate a user
migrating
```

```
    // In the real world user accounts would just be in a database
    if (!_mockDatabaseUserAccountsList.Any(f = >
f.Username.Equals("sampleUsername")))
            {
        //If the list is empty InitializeSampleUserAccountsAsync and
return the list
        await InitializeSampleUserAccountsAsync();
    }
}
```

- The user accounts list in mock store can now be saved and loaded. Other parts of the application will need to have access to this list so there will need to be some methods to retrieve this data. Underneath the **InitializeSampleUserAccountsAsync** method, add the following methods to get data. They will allow you to get a user ID, a single user, a list of users for a specific Windows Hello device, and also get the public key for the user on a specific device.

cs

```
public Guid GetUserId(string username)
{
    if (_mockDatabaseUserAccountsList.Any())
    {
        UserAccount account =
_mockDatabaseUserAccountsList.FirstOrDefault(f =>
f.Username.Equals(username));
        if (account != null)
        {
            return account.UserId;
        }
    }
    return Guid.Empty;
}

public UserAccount GetUserAccount(Guid userId)
{
    return _mockDatabaseUserAccountsList.FirstOrDefault(f =>
f.UserId.Equals(userId));
}

public List<UserAccount> GetUserAccountsForDevice(Guid deviceId)
{
    var usersForDevice = new List<UserAccount>();

    foreach (UserAccount account in _mockDatabaseUserAccountsList)
    {
        if (account.WindowsHelloDevices.Any(f =>
f.DeviceId.Equals(deviceId)))
        {
            usersForDevice.Add(account);
        }
    }
```

```
    return usersForDevice;
}

public byte[] GetPublicKey(Guid userId, Guid deviceId)
{
    UserAccount account =
_mockDatabaseUserAccountsList.FirstOrDefault(f =>
f.UserId.Equals(userId));
    if (account != null)
    {
        if (account.WindowsHelloDevices.Any())
        {
            return account.WindowsHelloDevices.FirstOrDefault(p =>
p.DeviceId.Equals(deviceId)).PublicKey;
        }
    }
    return null;
}
```

- The next methods to implement will handle simple operations to add an account, remove an account, and also remove a device. Removing a device is needed as Windows Hello is device-specific. For each device to which you log in, a new public and private key pair will be created by Windows Hello. It's like having a different password for each device you sign in on, the only thing is you don't need to remember all those passwords; the server does. Add the following methods into the MockStore.cs.

cs

```
public async Task<UserAccount> AddAccountAsync(string username)
{
    UserAccount newAccount = null;
    try
    {
        newAccount = new UserAccount()
        {
            UserId = Guid.NewGuid(),
            Username = username,
        };

        _mockDatabaseUserAccountsList.Add(newAccount);
        await SaveAccountListAsync();
    }
    catch (Exception)
    {
        throw;
    }
    return newAccount;
}
```

```
public async Task<bool> RemoveAccountAsync(Guid userId)
{
    UserAccount userAccount = GetUserAccount(userId);
    if (userAccount != null)
    {
        _mockDatabaseUserAccountsList.Remove(userAccount);
        await SaveAccountListAsync();
        return true;
    }
    return false;
}

public async Task<bool> RemoveDeviceAsync(Guid userId, Guid deviceId)
{
    UserAccount userAccount = GetUserAccount(userId);
    WindowsHelloDevice deviceToRemove = null;
    if (userAccount != null)
    {
        foreach (WindowsHelloDevice device in
userAccount.WindowsHelloDevices)
        {
            if (device.DeviceId.Equals(deviceId))
            {
                deviceToRemove = device;
                break;
            }
        }
    }

    if (deviceToRemove != null)
    {
        //Remove the WindowsHelloDevice
        userAccount.WindowsHelloDevices.Remove(deviceToRemove);
        await SaveAccountListAsync();
    }

    return true;
}
```

- In the **MockStore** class add a method that will add Windows Hello related information to an existing **UserAccount**. This method will be called "WindowsHelloUpdateDetailsAsync" and will take parameters to identify the user, and the Windows Hello details. The **KeyAttestationResult** has been commented out when creating a WindowsHelloDevice, in a real world application you would require this.

```cs
using System.Threading.Tasks;
using Windows.Security.Credentials;

public async Task WindowsHelloUpdateDetailsAsync(Guid userId, Guid
```

```
deviceId, byte[] publicKey,
    KeyCredentialAttestationResult keyAttestationResult)
{
    UserAccount existingUserAccount = GetUserAccount(userId);
    if (existingUserAccount != null)
    {
        if (!existingUserAccount.WindowsHelloDevices.Any(f =>
f.DeviceId.Equals(deviceId)))
        {
            existingUserAccount.WindowsHelloDevices.Add(new
WindowsHelloDevice()
            {
                DeviceId = deviceId,
                PublicKey = publicKey,
                // KeyAttestationResult = keyAttestationResult
            });
        }
    }
    await SaveAccountListAsync();
}
```

- The **MockStore** class is now complete, as this represents the database it should be considered private. In order to access the **MockStore**, an **AuthService** class is needed to manipulate the database data. In the **AuthService** folder create a new class called "AuthService.cs". Change the class scope to public and add a singleton instance pattern to make sure only one instance is ever created.

cs

```
namespace WindowsHelloLogin.AuthService
{
    public class AuthService
    {
        // Singleton instance of the AuthService
        // The AuthService is a mock of what a real world server and
service implementation would be
        private static AuthService _instance;
        public static AuthService Instance
        {
            get
            {
                if (null == _instance)
                {
                    _instance = new AuthService();
                }
                return _instance;
            }
        }

        private AuthService()
        { }
```

```
    }
}
```

- The **AuthService** class needs to create an instance of the **MockStore** class and provide access to the properties of the **MockStore** object.

cs

```
namespace WindowsHelloLogin.AuthService
{
    public class AuthService
    {
        //Singleton instance of the AuthService
        //The AuthService is a mock of what a real world server and
database implementation would be
        private static AuthService _instance;
        public static AuthService Instance
        {
            get
            {
                if (null == _instance)
                {
                    _instance = new AuthService();
                }
                return _instance;
            }
        }

        private AuthService()
        { }

        private MockStore _mockStore = new();

        public Guid GetUserId(string username)
        {
            return _mockStore.GetUserId(username);
        }

        public UserAccount GetUserAccount(Guid userId)
        {
            return _mockStore.GetUserAccount(userId);
        }

        public List<UserAccount> GetUserAccountsForDevice(Guid
deviceId)
        {
            return _mockStore.GetUserAccountsForDevice(deviceId);
        }
    }
}
```

- You need methods in the **AuthService** class to access add, remove, and update Windows Hello details methods in the **MockStore** object. At the end of the **AuthService** class definition, add the following methods.

```cs
using System.Threading.Tasks;
using Windows.Security.Credentials;

public async Task RegisterAsync(string username)
{
    await _mockStore.AddAccountAsync(username);
}

public async Task<bool> WindowsHelloRemoveUserAsync(Guid userId)
{
    return await _mockStore.RemoveAccountAsync(userId);
}

public async Task<bool> WindowsHelloRemoveDeviceAsync(Guid userId, Guid
deviceId)
{
    return await _mockStore.RemoveDeviceAsync(userId, deviceId);
}

public async Task WindowsHelloUpdateDetailsAsync(Guid userId, Guid
deviceId, byte[] publicKey,
    KeyCredentialAttestationResult keyAttestationResult)
{
    await _mockStore.WindowsHelloUpdateDetailsAsync(userId, deviceId,
publicKey, keyAttestationResult);
}
```

- The **AuthService** class needs to provide a method to validate credentials. This method will take a username and password and make sure that account exists and the password is valid. An existing system would have an equivalent method to this that checks the user is authorized. Add the following **ValidateCredentials** method to the AuthService.cs file.

```cs
public bool ValidateCredentials(string username, string password)
{
    if (!string.IsNullOrEmpty(username) &&
!string.IsNullOrEmpty(password))
    {
        // This would be used for existing accounts migrating to use
Windows Hello
        Guid userId = GetUserId(username);
        if (userId != Guid.Empty)
```

```
        {
            UserAccount account = GetUserAccount(userId);
            if (account != null)
            {
                if (string.Equals(password, account.Password))
                {
                    return true;
                }
            }
        }
    }
    return false;
}
```

- The **AuthService** class needs a request challenge method that returns a challenge to the client to validate whether the user is who they claim to be. Then another method is needed in the **AuthService** class to receive the signed challenge back from the client. For this hands on lab, the method of how you determine if the signed challenge has been completed has been left incomplete. Every implementation of Windows Hello into an existing authentication system will be slightly different. The public key stored on the server needs to match with the result the client returned to the server. Add these two methods to AuthService.cs.

cs

```
using Windows.Security.Cryptography;
using Windows.Storage.Streams;

public IBuffer WindowsHelloRequestChallenge()
{
    return CryptographicBuffer.ConvertStringToBinary("ServerChallenge",
BinaryStringEncoding.Utf8);
}

public bool SendServerSignedChallenge(Guid userId, Guid deviceId,
byte[] signedChallenge)
{
    // Depending on your company polices and procedures this step will
be different
    // It is at this point you will need to validate the
signedChallenge that is sent back from the client.
    // Validation is used to ensure the correct user is trying to
access this account.
    // The validation process will use the signedChallenge and the
stored PublicKey
    // for the username and the specific device signin is called from.
    // Based on the validation result you will return a bool value to
allow access to continue or to block the account.

    // For this sample validation will not happen as a best practice
solution does not apply and will need to
```

```
        // be configured for each company.
    // Simply just return true.

    // You could get the User's Public Key with something similar to
the following:
    byte[] userPublicKey = _mockStore.GetPublicKey(userId, deviceId);
    return true;
}
```

Exercise 2: Client Side Logic

In this exercise, you will be changing the client side views and helper classes from the first lab to use the **AuthService** class. In the real world, the **AuthService** would be the authentication server and you would need to use Web API's to send and receive data from the server. For this hands on lab, the client and server are both local to keep things simple. The objective is to learn how to use the Windows Hello APIs.

- In the MainPage.xaml.cs, you can remove the **AccountHelper.LoadAccountListAsync** method call in the loaded method as the **AuthService** class creates an instance of the **MockStore** to load the accounts list. The `Loaded` method should now look like the snippet below. Note that the async method definition is removed as nothing is being awaited.

  cs

  ```
  private void MainPage_Loaded(object sender, RoutedEventArgs e)
  {
      Frame.Navigate(typeof(UserSelection));
  }
  ```

- Update the **Login** page interface to require a password be entered. This hands on lab demonstrates how an existing system could be migrated to use Windows Hello and existing accounts will have a username and a password. Also update the explanation at the bottom of the XAML to include the default password. Update the following XAML in Login.xaml.

  XML

  ```
  <Grid>
    <StackPanel>
      <TextBlock Text="Login" FontSize="36" Margin="4"
  TextAlignment="Center"/>

      <TextBlock x:Name="ErrorMessage" Text="" FontSize="20" Margin="4"
  Foreground="Red" TextAlignment="Center"/>
  ```

```
    <TextBlock Text="Enter your credentials below" Margin="0,0,0,20"
               TextWrapping="Wrap" Width="300"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>

    <StackPanel Orientation="Horizontal" HorizontalAlignment="Center">
      <!-- Username Input -->
      <TextBlock x:Name="UserNameTextBlock" Text="Username: "
                 FontSize="20" Margin="4" Width="100"/>
      <TextBox x:Name="UsernameTextBox"
PlaceholderText="sampleUsername" Width="200" Margin="4"/>
    </StackPanel>

    <StackPanel Orientation="Horizontal" HorizontalAlignment="Center">
      <!-- Password Input -->
      <TextBlock x:Name="PasswordTextBlock" Text="Password: "
                 FontSize="20" Margin="4" Width="100"/>
      <PasswordBox x:Name="PasswordBox"
PlaceholderText="samplePassword" Width="200" Margin="4"/>
    </StackPanel>

    <Button x:Name="LoginButton" Content="Login"
Background="DodgerBlue" Foreground="White"
            Click="LoginButton_Click" Width="80"
HorizontalAlignment="Center" Margin="0,20"/>

    <TextBlock Text="Don't have an account?"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>
    <TextBlock x:Name="RegisterButtonTextBlock" Text="Register now"

PointerPressed="RegisterButtonTextBlock_OnPointerPressed"
               Foreground="DodgerBlue"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16"/>

    <Border x:Name="WindowsHelloStatus" Background="#22B14C"
            Margin="0,20" Height="100">
      <TextBlock x:Name="WindowsHelloStatusText" Text="Windows Hello is
ready to use!"
                 Margin="4" TextAlignment="Center"
VerticalAlignment="Center" FontSize="20"/>
    </Border>

    <TextBlock x:Name="LoginExplanation" FontSize="24"
TextAlignment="Center" TextWrapping="Wrap"
               Text="Please Note: To demonstrate a login, validation
will only occur using the default username 'sampleUsername' and default
password 'samplePassword'"/>
  </StackPanel>
</Grid>
```

- In the code-behind file for the **Login** class, you will need to change the `Account` private variable at the top of the class to be a `UserAccount`. Change the `OnNavigateTo` event to cast the type to be a `UserAccount`. You will need the following using statement as well.

cs

```cs
using WindowsHelloLogin.AuthService;

namespace WindowsHelloLogin.Views
{
    public sealed partial class Login : Page
    {
        private UserAccount _account;
        private bool _isExistingAccount;

        public Login()
        {
            this.InitializeComponent();
        }

        protected override async void OnNavigatedTo(NavigationEventArgs
e)
        {
            //Check Windows Hello is setup and available on this
machine
            if (await
WindowsHelloHelper.WindowsHelloAvailableCheckAsync())
            {
                if (e.Parameter != null)
                {
                    _isExistingAccount = true;
                    //Set the account to the existing account being
passed in
                    _account = (UserAccount)e.Parameter;
                    UsernameTextBox.Text = _account.Username;
                    await SignInWindowsHelloAsync();
                }
            }
        }

        private async void LoginButton_Click(object sender,
RoutedEventArgs e)
        {
            ErrorMessage.Text = "";
            await SignInWindowsHelloAsync();
        }
    }
}
```

- As the **Login** page is using a `UserAccount` object instead of the previous `Account` object, the WindowsHelloHelper.cs will need to be updated to use a `UserAccount` as a parameter type for some methods. You will need to change the following parameters for the **CreateWindowsHelloKeyAsync**, **RemoveWindowsHelloAccountAsync**, and **GetWindowsHelloAuthenticationMessageAsync** methods. As the `UserAccount` class has a `Guid` for a *UserId*, you will start using the Id in more places to be more precise.

cs

```
public static async Task<bool> CreateWindowsHelloKeyAsync(Guid userId,
string username)
{
    KeyCredentialRetrievalResult keyCreationResult = await
KeyCredentialManager.RequestCreateAsync(username,
KeyCredentialCreationOption.ReplaceExisting);

    return true;
}

public static async Task RemoveWindowsHelloAccountAsync(UserAccount
account)
{

}
public static async Task<bool>
GetWindowsHelloAuthenticationMessageAsync(UserAccount account)
{
    KeyCredentialRetrievalResult openKeyResult = await
KeyCredentialManager.OpenAsync(account.Username);
    //Calling OpenAsync will allow the user access to what is available
in the app and will not require user credentials again.
    //If you wanted to force the user to sign in again you can use the
following:
    //var consentResult = await
Windows.Security.Credentials.UI.UserConsentVerifier.RequestVerification
Async(account.Username);
    //This will ask for the either the password of the currently signed
in Microsoft Account or the PIN used for Windows Hello.

    if (openKeyResult.Status == KeyCredentialStatus.Success)
    {
        //If OpenAsync has succeeded, the next thing to think about is
whether the client application requires access to backend services.
        //If it does here you would Request a challenge from the
Server. The client would sign this challenge and the server
        //would check the signed challenge. If it is correct it would
allow the user access to the backend.
        //You would likely make a new method called RequestSignAsync to
handle all this
```

```
        //for example, RequestSignAsync(openKeyResult);
        //Refer to the second Windows Hello sample for information on
how to do this.

        //For this sample there is not concept of a server implemented
so just return true.
        return true;
    }
    else if (openKeyResult.Status == KeyCredentialStatus.NotFound)
    {
        //If the _account is not found at this stage. It could be one
of two errors.
        //1. Windows Hello has been disabled
        //2. Windows Hello has been disabled and re-enabled cause the
Windows Hello Key to change.
        //Calling CreateWindowsHelloKeyAsync and passing through the
account will attempt to replace the existing Windows Hello Key for that
account.
        //If the error really is that Windows Hello is disabled then
the CreateWindowsHelloKeyAsync method will output that error.
        if (await CreateWindowsHelloKeyAsync(account.UserId,
account.Username))
        {
            //If the Windows Hello Key was again successfully created,
Windows Hello has just been reset.
            //Now that the Windows Hello Key has been reset for the
account retry sign in.
            return await
GetWindowsHelloAuthenticationMessageAsync(account);
        }
    }

    // Can't use Windows Hello right now, try again later
    return false;
}
```

- The **SignInWindowsHelloAsync** method in Login.xaml.cs file will need to be updated to use the **AuthService** instead of the **AccountHelper**. Validation of credentials will happen through the **AuthService**. For this hands on lab, the only configured account is "sampleUsername". This account is created in the **InitializeSampleUserAccountsAsync** method in MockStore.cs. Update the SignInWindowsHelloAsync method in Login.xaml.cs now to reflect the code snippet below.

```cs
private async Task SignInWindowsHelloAsync()
{
    if (_isExistingAccount)
    {
        if (await
```

```
WindowsHelloHelper.GetWindowsHelloAuthenticationMessageAsync(_account))
        {
            Frame.Navigate(typeof(Welcome), _account);
        }
    }
    else if
(AuthService.AuthService.Instance.ValidateCredentials(UsernameTextBox.T
ext, PasswordBox.Password))
    {
        Guid userId =
AuthService.AuthService.Instance.GetUserId(UsernameTextBox.Text);

        if (userId != Guid.Empty)
        {
            //Now that the account exists on server try and create the
necessary details and add them to the account
            if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(userId,
UsernameTextBox.Text))
            {
                Debug.WriteLine("Successfully signed in with Windows
Hello!");
                //Navigate to the Welcome Screen.
                _account =
AuthService.AuthService.Instance.GetUserAccount(userId);
                Frame.Navigate(typeof(Welcome), _account);
            }
            else
            {
                //The Windows Hello account creation failed.
                //Remove the account from the server as the details
were not configured
                await
AuthService.AuthService.Instance.WindowsHelloRemoveUserAsync(userId);

                ErrorMessage.Text = "Account Creation Failed";
            }
        }
    }
    else
    {
        ErrorMessage.Text = "Invalid Credentials";
    }
}
```

- As Windows Hello will create a different public and private key pair for each account on each device the **Welcome** page will need to display a list of registered devices for the logged in account and allow each one to be forgotten. In Welcome.xaml add in the following XAML underneath the `ForgetButton`. This will implement a forget device button, an error text area and a list to display all devices.

XML

```
<Grid>
  <StackPanel>
    <TextBlock x:Name="Title" Text="Welcome" FontSize="40"
TextAlignment="Center"/>
    <TextBlock x:Name="UserNameText" FontSize="28"
TextAlignment="Center"/>

    <Button x:Name="BackToUserListButton" Content="Back to User List"
Click="Button_Restart_Click"
            HorizontalAlignment="Center" Margin="0,20"
Foreground="White" Background="DodgerBlue"/>

    <Button x:Name="ForgetButton" Content="Forget Me"
Click="Button_Forget_User_Click"
            Foreground="White"
            Background="Gray"
            HorizontalAlignment="Center"/>

    <Button x:Name="ForgetDeviceButton" Content="Forget Device"
Click="Button_Forget_Device_Click"
            Foreground="White"
            Background="Gray"
            Margin="0,40,0,20"
            HorizontalAlignment="Center"/>

    <TextBlock x:Name="ForgetDeviceErrorTextBlock" Text="Select a
device first"
               TextWrapping="Wrap" Width="300" Foreground="Red"
               TextAlignment="Center" VerticalAlignment="Center"
FontSize="16" Visibility="Collapsed"/>

    <ListView x:Name="UserListView" MaxHeight="500" MinWidth="350"
Width="350" HorizontalAlignment="Center">
      <ListView.ItemTemplate>
        <DataTemplate>
          <Grid Background="Gray" Height="50" Width="350"
HorizontalAlignment="Center" VerticalAlignment="Stretch" >
            <TextBlock Text="{Binding DeviceId}"
HorizontalAlignment="Center" TextAlignment="Center"
VerticalAlignment="Center"
                       Foreground="White"/>
          </Grid>
        </DataTemplate>
      </ListView.ItemTemplate>
    </ListView>
  </StackPanel>
</Grid>
```

- In the Welcome.xaml.cs file, you need to change the private `Account` variable at the top of the class to be a private `UserAccount` variable. Then update the

`OnNavigatedTo` method to use the **AuthService** and retrieve information for the current account. When you have the account information you can set the `ItemsSource` of the list to display the devices. You will need to add a reference to the **AuthService** namespace.

cs

```
using WindowsHelloLogin.AuthService;

namespace WindowsHelloLogin.Views
{
    public sealed partial class Welcome : Page
    {
        private UserAccount _activeAccount;

        public Welcome()
        {
            InitializeComponent();
        }

        protected override void OnNavigatedTo(NavigationEventArgs e)
        {
            _activeAccount = (UserAccount)e.Parameter;
            if (_activeAccount != null)
            {
                UserAccount account =
AuthService.AuthService.Instance.GetUserAccount(_activeAccount.UserId);
                if (account != null)
                {
                    UserListView.ItemsSource =
account.WindowsHelloDevices;
                    UserNameText.Text = account.Username;
                }
            }
        }
    }
}
```

- As you will be using the **AuthService** when removing an account, the reference to the **AccountHelper** in the `Button_Forget_User_Click` method can be removed. The method should now look as below.

cs

```
private async void Button_Forget_User_Click(object sender,
RoutedEventArgs e)
{
    //Remove it from Windows Hello
    await
WindowsHelloHelper.RemoveWindowsHelloAccountAsync(_activeAccount);
```

```
    Debug.WriteLine($"User {_activeAccount.Username} deleted.");

    //Navigate back to UserSelection page.
    Frame.Navigate(typeof(UserSelection));
}
```

- The **WindowsHelloHelper** method is not using the **AuthService** to remove the account. You need to make a call to the **AuthService** and pass the *userId*.

```cs
public static async Task RemoveWindowsHelloAccountAsync(UserAccount
account)
{
    //Open the account with Windows Hello
    KeyCredentialRetrievalResult keyOpenResult = await
KeyCredentialManager.OpenAsync(account.Username);

    if (keyOpenResult.Status == KeyCredentialStatus.Success)
    {
        // In the real world you would send key information to server
to unregister
        await
AuthService.AuthService.Instance.WindowsHelloRemoveUserAsync(account.Us
erId);
    }

    //Then delete the account from the machines list of Windows Hello
Accounts
    await KeyCredentialManager.DeleteAsync(account.Username);
}
```

- Before you can finish implementing the **Welcome** page, you need to create a method in WindowsHelloHelper.cs that will allow a device to be removed. Create a new method that will call **WindowsHelloRemoveDeviceAsync** in **AuthService**.

```cs
public static async Task RemoveWindowsHelloDeviceAsync(UserAccount
account, Guid deviceId)
{
    await
AuthService.AuthService.Instance.WindowsHelloRemoveDeviceAsync(account.
UserId, deviceId);
}
```

- In Welcome.xaml.cs, implement the **Button_Forget_Device_Click** event handler. This will use the selected device from the list of devices and use the Windows Hello

helper to call remove device. Remember to make the event handler async.

```cs
private async void Button_Forget_Device_Click(object sender,
RoutedEventArgs e)
{
    WindowsHelloDevice selectedDevice = UserListView.SelectedItem as
WindowsHelloDevice;
    if (selectedDevice != null)
    {
        //Remove it from Windows Hello
        await
WindowsHelloHelper.RemoveWindowsHelloDeviceAsync(_activeAccount,
selectedDevice.DeviceId);

        Debug.WriteLine($"User {_activeAccount.Username} deleted.");

        if (!UserListView.Items.Any())
        {
            //Navigate back to UserSelection page.
            Frame.Navigate(typeof(UserSelection));
        }
    }
    else
    {
        ForgetDeviceErrorTextBlock.Visibility = Visibility.Visible;
    }
}
```

- The next page you will update is the **UserSelection** page. The **UserSelection** page will need to use the **AuthService** to retrieve all user accounts for the current device. Currently, there is no way for you get a device ID to pass to the **AuthService** so it can return user accounts for that device. In the **Utils** folder, create a new class called "Helpers.cs". Change the class scope to be public static and then add the following method that will allow you to retrieve the current device id.

```cs
using System;
using Windows.Security.ExchangeActiveSyncProvisioning;

namespace WindowsHelloLogin.Utils
{
    public static class Helpers
    {
        public static Guid GetDeviceId()
        {
            //Get the Device ID to pass to the server
```

```
            var deviceInformation = new EasClientDeviceInformation();
            return deviceInformation.Id;
        }
    }
}
```

- In the **UserSelection** page class, only the code-behind needs to change, not the user interface. In UserSelection.xaml.cs, update the **UserSelection_Loaded** method and the **UserSelectionChanged** method to use the `UserAccount` class instead of the `Account` class. You will also need to get all users for this device through the **AuthService**.

cs

```
using System.Linq;
using WindowsHelloLogin.AuthService;

namespace WindowsHelloLogin.Views
{
    public sealed partial class UserSelection : Page
    {
        public UserSelection()
        {
            InitializeComponent();
            Loaded += UserSelection_Loaded;
        }

        private void UserSelection_Loaded(object sender,
RoutedEventArgs e)
        {
            List<UserAccount> accounts =
AuthService.AuthService.Instance.GetUserAccountsForDevice(Helpers.GetDe
viceId());

            if (accounts.Any())
            {
                UserListView.ItemsSource = accounts;
                UserListView.SelectionChanged += UserSelectionChanged;
            }
            else
            {
                //If there are no accounts navigate to the Login page
                Frame.Navigate(typeof(Login));
            }
        }

        /// <summary>
        /// Function called when an account is selected in the list of
accounts
        /// Navigates to the Login page and passes the chosen account
        /// </summary>
        private void UserSelectionChanged(object sender,
```

```
RoutedEventArgs e)
        {
            if (((ListView)sender).SelectedValue != null)
            {
                UserAccount account = (UserAccount)
((ListView)sender).SelectedValue;
                if (account != null)
                {
                    Debug.WriteLine($"Account {account.Username}
selected!");
                }
                Frame.Navigate(typeof(Login), account);
            }
        }
    }
}
```

- The **WindowsHelloRegister** page needs to have the code-behind file updated. The user interface does not need any changes. In WindowsHelloRegister.xaml.cs, remove the private `Account` variable at the top of the class, as it's no longer needed. Update the **RegisterButton_Click_Async** event handler to use the **AuthService**. This method will create a new **UserAccount** and then try and update its account details. If Windows Hello fails to create a key, the account will be removed as the registration process failed.

cs

```
private async void RegisterButton_Click_Async(object sender,
RoutedEventArgs e)
{
    ErrorMessage.Text = "";

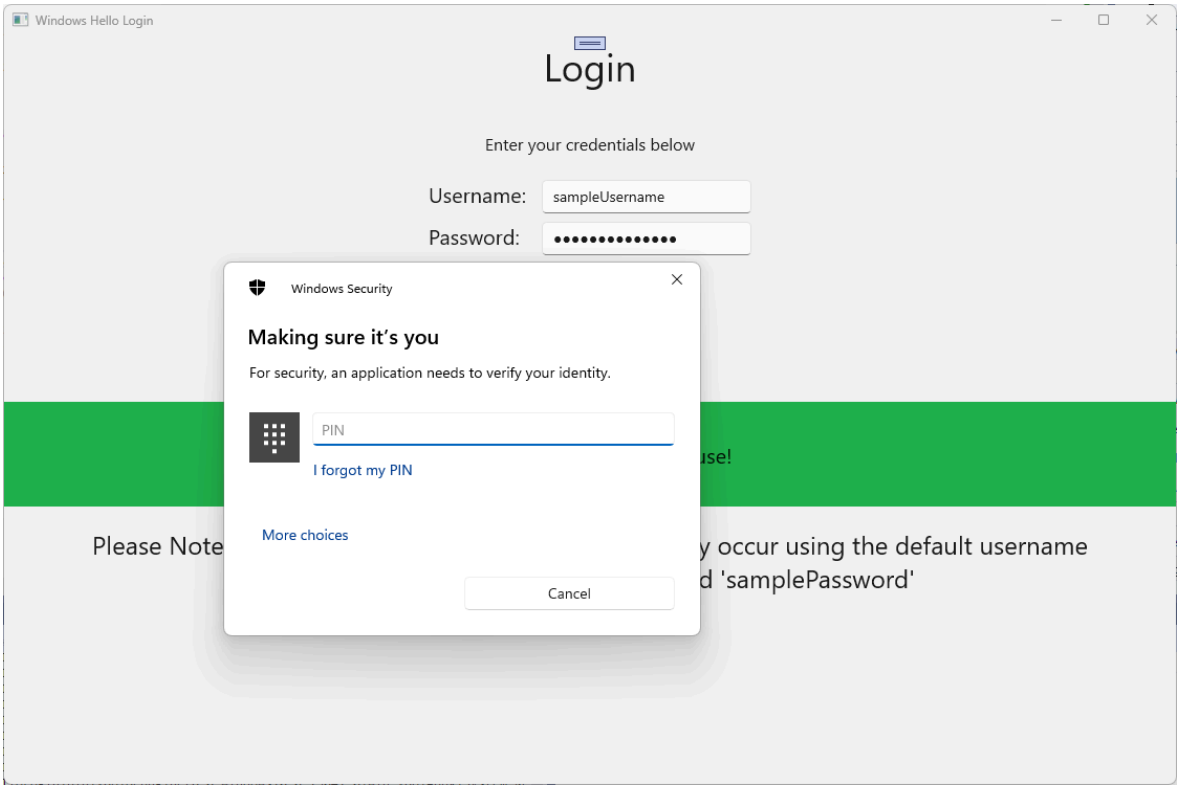
    //Validate entered credentials are acceptable
    if (!string.IsNullOrEmpty(UsernameTextBox.Text))
    {
        //Register an Account on the AuthService so that we can get
back a userId
        await
AuthService.AuthService.Instance.RegisterAsync(UsernameTextBox.Text);
        Guid userId =
AuthService.AuthService.Instance.GetUserId(UsernameTextBox.Text);

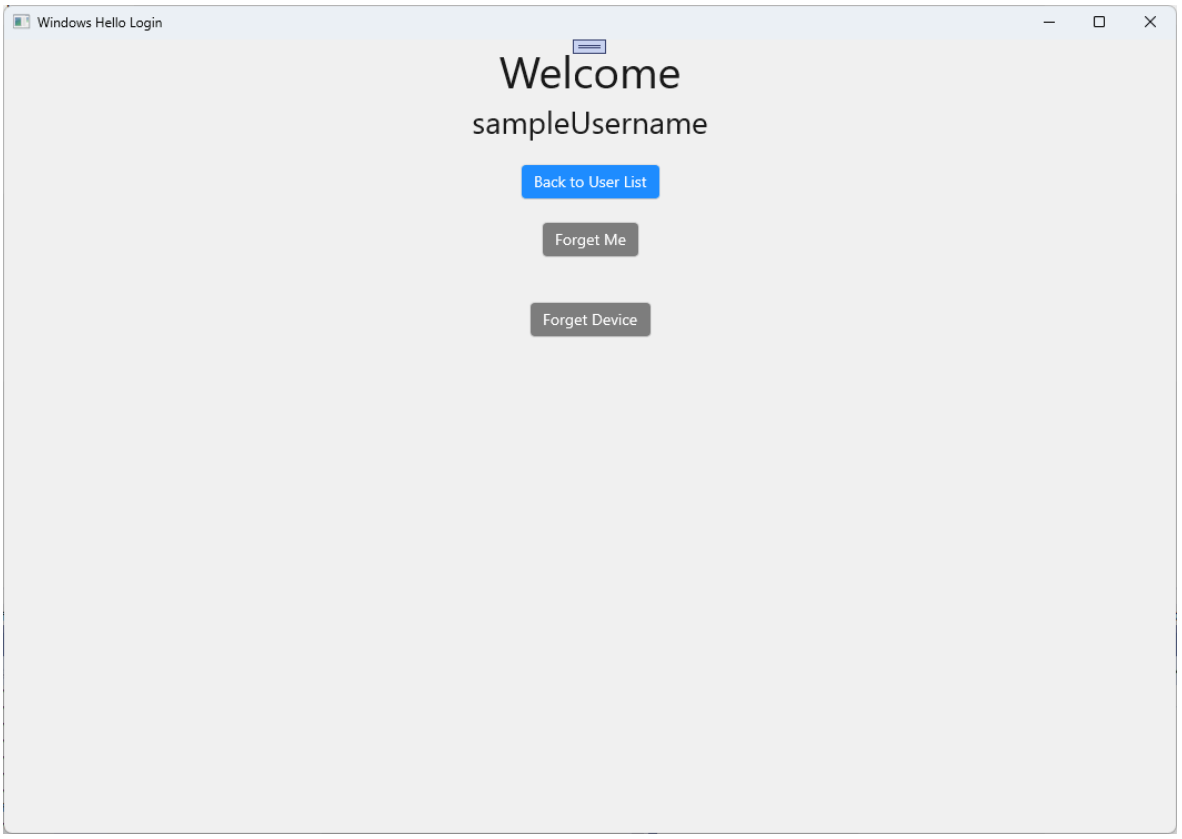
        if (userId != Guid.Empty)
        {
            //Now that the account exists on server try and create the
necessary details and add them to the account
            if (await
WindowsHelloHelper.CreateWindowsHelloKeyAsync(userId,
UsernameTextBox.Text))
            {
                //Navigate to the Welcome Screen.
```

```
                Frame.Navigate(typeof(Welcome),
AuthService.AuthService.Instance.GetUserAccount(userId));
            }
            else
            {
                //The Windows Hello account creation failed.
                //Remove the account from the server as the details
were not configured
                await
AuthService.AuthService.Instance.WindowsHelloRemoveUserAsync(userId);

                ErrorMessage.Text = "Account Creation Failed";
            }
        }
    }
    else
    {
        ErrorMessage.Text = "Please enter a username";
    }
}
```

- Build and run the application. Sign in to the sample user account with the credentials "sampleUsername" and "samplePassword". On the welcome screen, you may notice the Forget devices button is displayed, but there are no devices. When you are creating or migrating a user to work with Windows Hello the account information is not being pushed to the **AuthService**.





- To get the Windows Hello account information to the **AuthService**, the WindowsHelloHelper.cs will need to be updated. In the **CreateWindowsHelloKeyAsync** method, instead of only returning `true` in the case that's successful, you will need to call a new method which will try to get the **KeyAttestation**. While this hands on lab is not recording this information in the **AuthService**, you'll learn how you would get this information on the client side. Update the **CreateWindowsHelloKeyAsync** method as follows:

cs

```
public static async Task<bool> CreateWindowsHelloKeyAsync(Guid userId,
string username)
{
    KeyCredentialRetrievalResult keyCreationResult = await
KeyCredentialManager.RequestCreateAsync(username,
KeyCredentialCreationOption.ReplaceExisting);

    switch (keyCreationResult.Status)
    {
        case KeyCredentialStatus.Success:
            Debug.WriteLine("Successfully made key");
            await GetKeyAttestationAsync(userId, keyCreationResult);
            return true;
        case KeyCredentialStatus.UserCanceled:
            Debug.WriteLine("User cancelled sign-in process.");
            break;
        case KeyCredentialStatus.NotFound:
            // User needs to setup Windows Hello
            Debug.WriteLine($"Windows Hello is not set up!
```

```
{Environment.NewLine}Please go to Windows Settings and set up a PIN to
use it.");
                break;
            default:
                break;
        }

        return false;
    }
```

- Create a **GetKeyAttestationAsync** method in WindowsHelloHelper.cs. This method will demonstrate how to obtain all the necessary information that can be provided by Windows Hello for each account on a specific device.

cs

```
using Windows.Storage.Streams;

private static async Task GetKeyAttestationAsync(Guid userId,
KeyCredentialRetrievalResult keyCreationResult)
{
    KeyCredential userKey = keyCreationResult.Credential;
    IBuffer publicKey = userKey.RetrievePublicKey();
    KeyCredentialAttestationResult keyAttestationResult = await
userKey.GetAttestationAsync();
    IBuffer keyAttestation = null;
    IBuffer certificateChain = null;
    bool keyAttestationIncluded = false;
    bool keyAttestationCanBeRetrievedLater = false;
    KeyCredentialAttestationStatus keyAttestationRetryType = 0;

    if (keyAttestationResult.Status ==
KeyCredentialAttestationStatus.Success)
    {
        keyAttestationIncluded = true;
        keyAttestation = keyAttestationResult.AttestationBuffer;
        certificateChain = keyAttestationResult.CertificateChainBuffer;
        Debug.WriteLine("Successfully made key and attestation");
    }
    else if (keyAttestationResult.Status ==
KeyCredentialAttestationStatus.TemporaryFailure)
    {
        keyAttestationRetryType =
KeyCredentialAttestationStatus.TemporaryFailure;
        keyAttestationCanBeRetrievedLater = true;
        Debug.WriteLine("Successfully made key but not attestation");
    }
    else if (keyAttestationResult.Status ==
KeyCredentialAttestationStatus.NotSupported)
    {
        keyAttestationRetryType =
KeyCredentialAttestationStatus.NotSupported;
        keyAttestationCanBeRetrievedLater = false;
```

```
        Debug.WriteLine("Key created, but key attestation not
supported");
    }

    Guid deviceId = Helpers.GetDeviceId();

    //Update the Windows Hello details with the information we have
just fetched above.
    //await UpdateWindowsHelloDetailsAsync(userId, deviceId,
publicKey.ToArray(), keyAttestationResult);
}
```

- You may have noticed in the **GetKeyAttestationAsync** method that you just added the last line was commented out. This last line will be a new method you create that will send all the Windows Hello information to the **AuthService**. In the real world, you would need to send this to an actual server through a Web API.

cs

```
using System.Runtime.InteropServices.WindowsRuntime;
using System.Threading.Tasks;

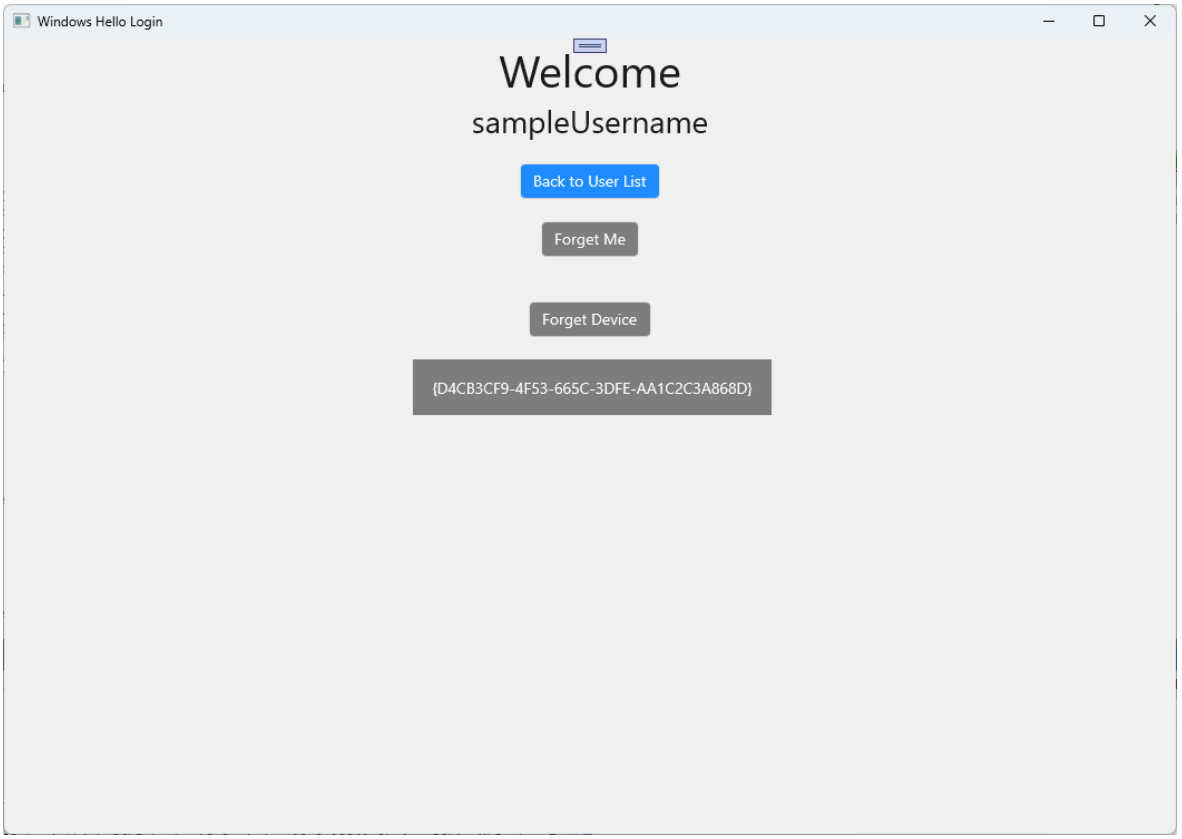
public static async Task<bool> UpdateWindowsHelloDetailsAsync(Guid
userId, Guid deviceId, byte[] publicKey, KeyCredentialAttestationResult
keyAttestationResult)
{
    //In the real world, you would use an API to add Windows Hello
signing info to server for the signed in account.
    //For this tutorial, we do not implement a Web API for our server
and simply mock the server locally.
    //The CreateWindowsHelloKey method handles adding the Windows Hello
account locally to the device using the KeyCredential Manager

    //Using the userId the existing account should be found and
updated.
    await
AuthService.AuthService.Instance.WindowsHelloUpdateDetailsAsync(userId,
deviceId, publicKey, keyAttestationResult);
    return true;
}
```

- Uncomment the last line in the **GetKeyAttestationAsync** method so that the Windows Hello information is being sent to the **AuthService**.

- Build and run the application and sign in with the default credentials as before. On the **Welcome** page, you will now see that the device Id is displayed. If you signed in on another device that would also be displayed here (if you had a cloud hosted auth service). For this hands on lab, the actual device Id is being displayed. In a real

implementation, you would want to display a friendly name that a person could understand and use to identify each device.



- To complete this hands on lab, you need a request and challenge for the user when they select from the user selection page and sign back in. The **AuthService** has two methods that you created to request a challenge, one that uses a signed challenge. In WindowsHelloHelper.cs, create a new method named **RequestSignAsync**. This will request a challenge from the **AuthService**, locally sign that challenge using a Windows Hello API and send the signed challenge to the **AuthService**. In this hands on lab, the **AuthService** will receive the signed challenge and return `true`. In an actual implementation, you would need to implement a verification mechanism to determine if the challenge was signed by the correct user on the correct device. Add the method below to the WindowsHelloHelper.cs

cs

```
private static async Task<bool> RequestSignAsync(Guid userId,
KeyCredentialRetrievalResult openKeyResult)
{
    // Calling userKey.RequestSignAsync() prompts the uses to enter the
PIN or use Biometrics (Windows Hello).
    // The app would use the private key from the user account to sign
the sign-in request (challenge)
    // The client would then send it back to the server and await the
servers response.
    IBuffer challengeMessage =
```

```
AuthService.AuthService.Instance.WindowsHelloRequestChallenge();
    KeyCredential userKey = openKeyResult.Credential;
    KeyCredentialOperationResult signResult = await
userKey.RequestSignAsync(challengeMessage);

    if (signResult.Status == KeyCredentialStatus.Success)
    {
        // If the challenge from the server is signed successfully
        // send the signed challenge back to the server and await the
servers response
        return
AuthService.AuthService.Instance.SendServerSignedChallenge(
            userId, Helpers.GetDeviceId(),
signResult.Result.ToArray());
    }
    else if (signResult.Status == KeyCredentialStatus.UserCanceled)
    {
        // User cancelled the Windows Hello PIN entry.
    }
    else if (signResult.Status == KeyCredentialStatus.NotFound)
    {
        // Must recreate Windows Hello key
    }
    else if (signResult.Status ==
KeyCredentialStatus.SecurityDeviceLocked)
    {
        // Can't use Windows Hello right now, remember that hardware
failed and suggest restart
    }
    else if (signResult.Status == KeyCredentialStatus.UnknownError)
    {
        // Can't use Windows Hello right now, try again later
    }

    return false;
}
```

- In the **WindowsHelloHelper** class, call the **RequestSignAsync** method from the **GetWindowsHelloAuthenticationMessageAsync** method.

cs

```
public static async Task<bool>
GetWindowsHelloAuthenticationMessageAsync(UserAccount account)
{
    KeyCredentialRetrievalResult openKeyResult = await
KeyCredentialManager.OpenAsync(account.Username);
    // Calling OpenAsync will allow the user access to what is
available in the app and will not require user credentials again.
    // If you wanted to force the user to sign in again you can use the
following:
    // var consentResult = await
Windows.Security.Credentials.UI.UserConsentVerifier.RequestVerification
```

```
Async(account.Username);
    // This will ask for the either the password of the currently
signed in Microsoft Account or the PIN used for Windows Hello.

    if (openKeyResult.Status == KeyCredentialStatus.Success)
    {
        //If OpenAsync has succeeded, the next thing to think about is
whether the client application requires access to backend services.
        //If it does here you would Request a challenge from the
Server. The client would sign this challenge and the server
        //would check the signed challenge. If it is correct it would
allow the user access to the backend.
        //You would likely make a new method called RequestSignAsync to
handle all this
        //for example, RequestSignAsync(openKeyResult);
        //Refer to the second Windows Hello sample for information on
how to do this.

        return await RequestSignAsync(account.UserId, openKeyResult);
    }
    else if (openKeyResult.Status == KeyCredentialStatus.NotFound)
    {
        //If the _account is not found at this stage. It could be one
of two errors.
        //1. Windows Hello has been disabled
        //2. Windows Hello has been disabled and re-enabled cause the
Windows Hello Key to change.
        //Calling CreateWindowsHelloKeyAsync and passing through the
account will attempt to replace the existing Windows Hello Key for that
account.
        //If the error really is that Windows Hello is disabled then
the CreateWindowsHelloKeyAsync method will output that error.
        if (await CreateWindowsHelloKeyAsync(account.UserId,
account.Username))
        {
            //If the Windows Hello Key was again successfully created,
Windows Hello has just been reset.
            //Now that the Windows Hello Key has been reset for the
_account retry sign in.
            return await
GetWindowsHelloAuthenticationMessageAsync(account);
        }
    }

    // Can't use Windows Hello right now, try again later
    return false;
}
```

- Throughout this exercise, you have updated the client side application to use the **AuthService**. By doing this, you have been able to eliminate the need for the **Account** class and the **AccountHelper** class. Delete the **Account** class, the **Models** folder, and the **AccountHelper** class in the **Utils** folder. You'll need to remove all

reference to the `WindowsHelloLogin.Models` namespace throughout the application before the solution will successfully build.

- Build and run the application and enjoy using Windows Hello with the mock service and database.

In this hands on lab, you have learned how to use the Windows Hello APIs to replace the need for passwords when using authentication from a Windows machine. When you consider how much energy is expended by people maintaining passwords and supporting lost passwords in existing systems, you should see the benefit of moving to this new Windows Hello system of authentication.

We have left as an exercise for you the details of how you'll implement the authentication on the service and server side. It's expected that most developers will have existing systems that will need to be migrated to start working with Windows Hello. The details of each of these system will differ.

Speech, voice, and conversation in Windows 11 and Windows 10

Article • 07/10/2024

Speech can be an effective, natural, and enjoyable way for people to interact with your Windows applications, complementing, or even replacing, traditional interaction experiences based on mouse, keyboard, touch, controller, or gestures.

Speech-based features such as speech recognition, dictation, speech synthesis (also known as text-to-speech or TTS), and conversational voice assistants (such as Cortana or Alexa) can provide accessible and inclusive user experiences that enable people to use your applications when other input devices might not suffice.

This page provides information on how the various Windows development frameworks provide speech recognition, speech synthesis, and conversation support for developers building Windows applications.

Platform-specific documentation

Universal Windows Platform (UWP)

Build speech-enabled apps on the modern platform for Windows 10 (and later) applications and games, on any Windows device (including PCs, phones, Xbox, HoloLens, and more), and publish them to the Microsoft Store.

Speech interactions

Speech recognition

Continuous dictation

Speech synthesis

Conversational agents

Cortana interactions in Windows apps
(not supported in Windows 10 May 2020 Update and newer)

Win32 platform

Develop speech-enabled applications for Windows desktop and Windows Server using the tools, information, and sample engines and applications provided here.

Microsoft Speech Platform - Software Development Kit (SDK) (Version 11)

Microsoft Speech SDK, version 5.1

.NET Framework

Develop accessible apps and tools on the established platform for managed Windows applications with a XAML UI model and the .NET Framework.

System.Speech Programming Guide for .NET Framework

Azure speech services

Integrate speech processing into apps and services.

Speech to text

Text to speech

Speech translation

Speaker Recognition

Voice-first virtual assistants

Legacy features

Legacy, deprecated, and/or unsupported versions of Microsoft speech and conversation technology.

Microsoft Agent

Microsoft Speech API (SAPI) 5.3

Microsoft Speech API (SAPI) 5.4

The Bing Speech Recognition Control

Samples

Download and run full Windows samples that demonstrate various accessibility features and functionality.

Code sample browser

The new samples browser (replaces the MSDN Code Gallery).

Windows classic samples on GitHub

These samples demonstrate the functionality and programming model for Windows and Windows Server.

Universal Windows Platform (UWP) samples on GitHub

These samples demonstrate the API usage patterns for the Universal Windows Platform (UWP) in the Windows Software Development Kit (SDK) for Windows 10 and later.

WinUI 2 Gallery

This app demonstrates the various Xaml controls supported in the Fluent Design System.

User interface and input

Article • 10/27/2022

This article provides an overview of the Windows UI frameworks that are currently maintained by Microsoft and compares their capabilities.

Microsoft produces both UI frameworks and app platforms. App platforms typically include a UI framework, while UI frameworks are either standalone (not shipped with an app platform) or can be used with multiple app platforms (see Choose your app platform).

The frameworks discussed here include WinUI for both Windows App SDK (WinUI 3) and UWP (WinUI 2), Windows Presentation Foundation (WPF), and Windows Forms (WinForms).

User interface fundamentals

When building a modern Windows app, you have a selection of UI frameworks to choose from. UI frameworks provide your app with built in controls, styles, animations, input handling, and more.

There are five main components that go into creating a user interface for your Windows app. These components are usually built into each UI framework.

- Controls and styles
    - A control is a UI element that displays content or enables interaction. Controls are the building blocks of the user interface.

      Here's an example of a Button control that's available in UWP, WinUI 2, and WinUI 3. When you place this control into your app, it automatically receives the default design that the UI framework provides.

    - Styles consist of colors, typography, icons, Fluent materials, and more that can be used throughout your app's design to create a truly unique experience.

Here's an example of a style component called Acrylic, available in WinUI 2 and WinUI 3. Acrylic is a brush that you can use on surfaces within your app or as the background of your app. It provides a translucent texture.

- Input and interaction

  End users may interact with your app and provide input to your app (such as selection or typing) through different methods. Some examples of input are:
  - Mouse
  - Touch
  - Gamepad
  - Pen
  - Keyboard
  - Surface Dial
  - Touchpad
  - Speech

- Device support

  End users access Windows apps on a variety of devices, and UI frameworks may only support certain ones. Some common devices for Windows apps to run on are:
  - PCs (often referred to as "desktop", but includes laptops as well)
  - Tablets
  - HoloLens
  - Xbox
  - Surface Hub

- Motion and animation

Built-in animations can really give your app a polished look and feel, and provide consistency with first-party apps throughout Windows.

An example of a built-in animation in UWP, WinUI 2, and WinUI 3 is the animation that occurs when the end user switches between light and dark mode. When the end user switches modes for their entire PC, the app's UI will automatically update as well with a transition animation.

- Usability and accessibility

  In order to ensure your app is delightful to use for every single user, you must take accessibility into account.

  UI frameworks provide built-in accessibility to controls and styles with purposeful keyboard behavior, screenreader support and more. Many also provide APIs for accessible actions in custom controls, like interacting with screenreaders.

UI frameworks

Each UI framework released by Microsoft has unique capabilities, follows different design languages, and provides different experiences to the end user. This section will compare all the main UI frameworks that you'll be choosing from when you begin to build your app.

The table below shows a brief summary of a few main capabilities between these UI frameworks. For more details on each framework, navigate through the tabs further below.

Expand table

Capability	Windows App SDK (WinUI 3)	WinUI 2 for UWP	WPF	WinForms
Languages supported	C#/.NET 6 and later, C++/WinRT	C#/.NET Native, C++/WinRT, C++/CX, VB	C#/.NET 6 (and later) and .NET Framework, C++/CLI (Managed Extensions for C++), F#, VB	C#/.NET 6 (and later) and .NET Framework, C++/CLI (Managed Extensions for C++), F#, VB
Devices supported	PCs (incl. laptops and tablets), support for all Windows 10	All Windows 10 devices (PCs, tablets, HoloLens,	Desktop PCs and laptops	Desktop PCs and laptops

Capability	Windows App SDK (WinUI 3)	WinUI 2 for UWP	WPF	WinForms
	devices coming soon	Xbox, Surface Dial, and more)		
Inputs supported	All Windows 10 inputs supported	All Windows 10 inputs supported	Mouse and keyboard	Mouse and keyboard
Windows OS version supported	Windows 10 version 1809 or later	Windows 10 version 1703 or later	Windows XP or later	Windows XP or later
WebView support	Chromium-based WebView2	Non-chromium WebView	WebView2 support coming soon	WebView2 support coming soon
Open Source	Coming soon	Yes	Yes (.NET 6 and later only)	Yes (.NET 6 and later only)

For more information about each of these UI frameworks, see the information on the following tabs.

Windows App SDK (WinUI 3)

Windows App SDK (WinUI 3)

For most new Windows apps, we recommend WinUI with the Windows App SDK (WinUI 3) to build your user interface. WinUI 3 provides consistent, intuitive, and accessible experiences using the latest user interface (UI) patterns.

WinUI 3 is completely decoupled from the Windows OS and ships as a part of the Windows App SDK, which is a set of tools and components that represent the next evolution in the Windows app development platform.

WinUI 3 is the latest generation of WinUI. WinUI 2 and 3 share many of the same controls, styles, and other UI fundamentals (see Comparison of WinUI 2 and WinUI 3).

Key app scenarios enabled by WinUI 3

- Modern Windows apps that need to run on a variety of modern devices, with a range of modern inputs
- Desktop/Win32 apps that are written in C++

- Graphics-heavy apps or games that want to take advantage of DirectX and Win2D
- Apps with a lot of integrated web content that need high-performance
- Apps that seek to provide experiences that "fit right in" on the Windows OS and with other first party Windows apps

Apply Mica or Acrylic materials in desktop apps for Windows 11

Article • 07/16/2024

Materials in Windows 11 are visual effects applied to UX surfaces that resemble real life artifacts. Occluding materials, like Mica and Acrylic, are used as base layers beneath interactive UI controls.

Mica is an opaque material that incorporates the user's theme and desktop wallpaper to create a highly personalized appearance. Mica is designed for performance as it only captures the background wallpaper once to create its visualization, so we recommend it for the foundation layer of your app, especially in the title bar area.

Acrylic is a semi-transparent material that replicates the effect of frosted glass. It's used only for transient, light-dismiss surfaces such as flyouts and context menus.

This article describes how to apply Mica or Acrylic as the base layer of your Windows App SDK/WinUI 3 XAML app.

> **Note**
>
> - To use an in-app AcrylicBrush, see Acrylic material.
> - To use backdrop materials in a Win32 app, see Apply Mica in Win32 desktop apps for Windows 11.
> - To use backdrop materials in a UWP/WinUI 2 app, see Apply Mica with WinUI 2 for UWP or Acrylic material.

How to use a backdrop material

✓ **Important APIs**: Window.SystemBackdrop property, MicaBackdrop class, DesktopAcrylicBackdrop class, SystemBackdropConfiguration class

Open the WinUI 3 Gallery app and see the System Backdrops in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

To apply Mica or Acrylic material to your app, you set the `SystemBackdrop` property to a XAML SystemBackdrop (typically, one of the built-in backdrops, MicaBackdrop or DesktopAcrylicBackdrop).

These elements have a `SystemBackdrop` property:

- CommandBarFlyoutCommandBar.SystemBackdrop
- ContentIsland.SystemBackdrop
- DesktopWindowXamlSource.SystemBackdrop
- FlyoutBase.SystemBackdrop
- MenuFlyoutPresenter.SystemBackdrop
- Popup.SystemBackdrop
- Window.SystemBackdrop

These examples show how to set the system backdrop in XAML and in code.

Mica

Mica is typically used as the backdrop for an app Window.

XAML

```
<Window
    ... >

    <Window.SystemBackdrop>
        <MicaBackdrop Kind="BaseAlt"/>
    </Window.SystemBackdrop>

</Window>
```

C#

```
public MainWindow()
{
    this.InitializeComponent();

    SystemBackdrop = new MicaBackdrop()
                         { Kind = MicaKind.BaseAlt };
}
```

Acrylic

Acrylic is typically used as the backdrop for transient UI, like a flyout.

XAML

```
<Flyout
    ... >

    <Flyout.SystemBackdrop>
        <DesktopAcrylicBackdrop/>
    </Flyout.SystemBackdrop>
</Flyout>
```

C#

```
Flyout flyout = new Flyout()
{
    SystemBackdrop = new DesktopAcrylicBackdrop()
};
```

How to use a system backdrop controller

> **Note**
>
> Starting with Windows App SDK 1.3, you can apply material by setting the `Window.SystemBackdrop` property to a XAML `SystemBackdrop` as described in the previous section. This is the recommended way to apply a material.
>
> The remainder of this article shows how to use the Composition MicaController and DesktopAcrylicController APIs.

To use a backdrop material in your app, you can use one of the controllers that implements the ISystemBackdropController interface (MicaController or DesktopAcrylicController). These classes manage both the rendering of the system backdrop material as well as the handling of system policy for the material.

To use Mica as your backdrop material, create a MicaController object. To use Acrylic, create a DesktopAcrylicController object. The set up and supporting code is the same for each type of system backdrop material.

This code shows how to create a `MicaController`.

C#

```
MicaController m_backdropController;

bool TrySetSystemBackdrop()
```

```
{
    if (MicaController.IsSupported())
    {
        ...
        m_backdropController = new MicaController();
        ...
    }
}
```

To use the Mica Alt variant of Mica, create a `MicaController` object and set the Kind property to MicaKind.BaseAlt.

C#

```
MicaController m_backdropController;

bool TrySetSystemBackdrop()
{
    if (MicaController.IsSupported())
    {
        ...
        m_backdropController = new MicaController()
        {
            Kind = MicaKind.BaseAlt
        };
        ...
    }
}
```

This code shows how to create a `DesktopAcrylicController`.

C#

```
DesktopAcrylicController m_backdropController;

bool TrySetSystemBackdrop()
{
    if (DesktopAcrylicController.IsSupported())
    {
        ...
        m_backdropController = new DesktopAcrylicController();
        ...
    }
}
```

The controller reacts to the system Light and Dark themes by default. To override this behavior, you can set the following properties on the controller:

- FallbackColor

- LuminosityOpacity
- TintColor
- TintOpacity

> **Note**
>
> After customizing any of the controller's four properties, it no longer applies default Light or Dark values when the associated SystemBackdropConfiguration.Theme changes. You need to manually update those properties to match the new theme.

In order to use the backdrop material in your app, the following items are required:

- **System support**

  The system where the app runs must support the backdrop material. Call the MicaController.IsSupported or DesktopAcrylicController.IsSupported method to ensure the backdrop material is supported at runtime.

- **A valid target**

  You must provide a target that implements the ICompositionSupportsSystemBackdrop interface. In a XAML app, the XAML Window implements this interface and is used as the backdrop target.

- **A SystemBackdropConfiguration object**

  The SystemBackdropConfiguration provides the system backdrop controller with app-specific policy information to properly configure the system backdrop material.

- **A DispatcherQueue object**.

  You need an available Windows.System.DispatcherQueue on the main XAML thread. See the `WindowsSystemDispatcherQueueHelper` class in the example code, or in the WinUI 3 Gallery sample.

Example: Use Mica in a Windows AppSDK/WinUI 3 app

This example shows how to set up the Mica backdrop material in a XAML app.

> **Tip**

>
> **C++/WinRT**: Windows App SDK Mica sample.

C#

```
using Microsoft.UI.Composition.SystemBackdrops;
using Microsoft.UI.Xaml;
using System.Runtime.InteropServices; // For DllImport
using WinRT; // required to support
Window.As<ICompositionSupportsSystemBackdrop>()

public sealed partial class MainWindow : Window
{
    WindowsSystemDispatcherQueueHelper m_wsdqHelper; // See below for
implementation.
    MicaController m_backdropController;
    SystemBackdropConfiguration m_configurationSource;

    public MainWindow()
    {
        this.InitializeComponent();

        TrySetSystemBackdrop();
    }

    bool TrySetSystemBackdrop()
    {
        if
(Microsoft.UI.Composition.SystemBackdrops.MicaController.IsSupported())
        {
            m_wsdqHelper = new WindowsSystemDispatcherQueueHelper();
            m_wsdqHelper.EnsureWindowsSystemDispatcherQueueController();

            // Create the policy object.
            m_configurationSource = new SystemBackdropConfiguration();
            this.Activated += Window_Activated;
            this.Closed += Window_Closed;
            ((FrameworkElement)this.Content).ActualThemeChanged +=
Window_ThemeChanged;

            // Initial configuration state.
            m_configurationSource.IsInputActive = true;
            SetConfigurationSourceTheme();

            m_backdropController = new
Microsoft.UI.Composition.SystemBackdrops.MicaController();
```

```
            // Enable the system backdrop.
            // Note: Be sure to have "using WinRT;" to support the
Window.As<...>() call.

m_backdropController.AddSystemBackdropTarget(this.As<Microsoft.UI.Compositio
n.ICompositionSupportsSystemBackdrop>());

m_backdropController.SetSystemBackdropConfiguration(m_configurationSource);
            return true; // succeeded
        }

        return false; // Mica is not supported on this system
    }

    private void Window_Activated(object sender, WindowActivatedEventArgs
args)
        {
            m_configurationSource.IsInputActive = args.WindowActivationState
!= WindowActivationState.Deactivated;
        }

XAML custom panels overview

Article • 04/06/2022

A *panel* is an object that provides a layout behavior for child elements it contains, when the Extensible Application Markup Language (XAML) layout system runs and your app UI is rendered.

> **Important APIs**: Panel, ArrangeOverride, MeasureOverride

You can define custom panels for XAML layout by deriving a custom class from the Panel class. You provide behavior for your panel by overriding the MeasureOverride and ArrangeOverride, supplying logic that measures and arranges the child elements.

The Panel base class

To define a custom panel class, you can either derive from the Panel class directly, or derive from one of the practical panel classes that aren't sealed, such as Grid or StackPanel. It's easier to derive from **Panel**, because it can be difficult to work around the existing layout logic of a panel that already has layout behavior. Also, a panel with behavior might have existing properties that aren't relevant for your panel's layout features.

From Panel, your custom panel inherits these APIs:

- The Children property.
- The Background, ChildrenTransitions and IsItemsHost properties, and the dependency property identifiers. None of these properties are virtual, so you don't typically override or replace them. You don't typically need these properties for custom panel scenarios, not even for reading values.
- The layout override methods MeasureOverride and ArrangeOverride. These were originally defined by FrameworkElement. The base Panel class doesn't override these, but practical panels like Grid do have override implementations that are implemented as native code and are run by the system. Providing new (or additive) implementations for **ArrangeOverride** and **MeasureOverride** is the bulk of the effort you need to define a custom panel.
- All the other APIs of FrameworkElement, UIElement and DependencyObject, such as Height, Visibility and so on. You sometimes reference values of these properties in your layout overrides, but they aren't virtual so you don't typically override or replace them.

This focus here is to describe XAML layout concepts, so you can consider all the possibilities for how a custom panel can and should behave in layout. If you'd rather jump right in and see an example custom panel implementation, see BoxPanel, an example custom panel.

The Children property

The **Children** property is relevant to a custom panel because all classes derived from **Panel** use the **Children** property as the place to store their contained child elements in a collection. **Children** is designated as the XAML content property for the **Panel** class, and all classes derived from **Panel** can inherit the XAML content property behavior. If a property is designated the XAML content property, that means that XAML markup can omit a property element when specifying that property in markup, and the values are set as immediate markup children (the "content"). For example, if you derive a class named **CustomPanel** from **Panel** that defines no new behavior, you can still use this markup:

XAML

```
<local:CustomPanel>
  <Button Name="button1"/>
  <Button Name="button2"/>
</local:CustomPanel>
```

When a XAML parser reads this markup, **Children** is known to be the XAML content property for all **Panel** derived types, so the parser will add the two **Button** elements to the **UIElementCollection** value of the **Children** property. The XAML content property facilitates a streamlined parent-child relationship in the XAML markup for a UI definition. For more info about XAML content properties, and how collection properties are populated when XAML is parsed, see the XAML syntax guide.

The collection type that's maintaining the value of the **Children** property is the **UIElementCollection** class. **UIElementCollection** is a strongly typed collection that uses **UIElement** as its enforced item type. **UIElement** is a base type that's inherited by hundreds of practical UI element types, so the type enforcement here is deliberately loose. But it does enforce that you couldn't have a **Brush** as a direct child of a **Panel**, and it generally means that only elements that are expected to be visible in UI and participate in layout will be found as child elements in a **Panel**.

Typically, a custom panel accepts any **UIElement** child element by a XAML definition, by simply using the characteristics of the **Children** property as-is. As an advanced scenario,

you could support further type checking of child elements, when you iterate over the collection in your layout overrides.

Besides looping through the **Children** collection in the overrides, your panel logic might also be influenced by `Children.Count`. You might have logic that is allocating space at least partly based on the number of items, rather than desired sizes and the other characteristics of individual items.

Overriding the layout methods

The basic model for the layout override methods (**MeasureOverride** and **ArrangeOverride**) is that they should iterate through all the children and call each child element's specific layout method. The first layout cycle starts when the XAML layout system sets the visual for the root window. Because each parent invokes layout on its children, this propagates a call to layout methods to every possible UI element that is supposed to be part of a layout. In XAML layout, there are two stages: measure, then arrange.

You don't get any built-in layout method behavior for **MeasureOverride** and **ArrangeOverride** from the base **Panel** class. Items in **Children** won't automatically render as part of the XAML visual tree. It is up to you to make the items known to the layout process, by invoking layout methods on each of the items you find in **Children** through a layout pass within your **MeasureOverride** and **ArrangeOverride** implementations.

There's no reason to call base implementations in layout overrides unless you have your own inheritance. The native methods for layout behavior (if they exist) run regardless, and not calling base implementation from overrides won't prevent the native behavior from happening.

During the measure pass, your layout logic queries each child element for its desired size, by calling the **Measure** method on that child element. Calling the **Measure** method establishes the value for the **DesiredSize** property. The **MeasureOverride** return value is the desired size for the panel itself.

During the arrange pass, the positions and sizes of child elements are determined in x-y space and the layout composition is prepared for rendering. Your code must call **Arrange** on each child element in **Children** so that the layout system detects that the element belongs in the layout. The **Arrange** call is a precursor to composition and rendering; it informs the layout system where that element goes, when the composition is submitted for rendering.

Many properties and values contribute to how the layout logic will work at runtime. A way to think about the layout process is that the elements with no children (generally the most deeply nested element in the UI) are the ones that can finalize measurements first. They don't have any dependencies on child elements that influence their desired size. They might have their own desired sizes, and these are size suggestions until the layout actually takes place. Then, the measure pass continues walking up the visual tree until the root element has its measurements and all the measurements can be finalized.

The candidate layout must fit within the current app window or else parts of the UI will be clipped. Panels often are the place where the clipping logic is determined. Panel logic can determine what size is available from within the MeasureOverride implementation, and may have to push the size restrictions onto the children and divide space amongst children so that everything fits as best it can. The result of layout is ideally something that uses various properties of all parts of the layout but still fits within the app window. That requires both a good implementation for layout logic of the panels, and also a judicious UI design on the part of any app code that builds a UI using that panel. No panel design is going to look good if the overall UI design includes more child elements than can possibly fit in the app.

A large part of what makes the layout system work is that any element that's based on FrameworkElement already has some of its own inherent behavior when acting as a child in a container. For example, there are several APIs of **FrameworkElement** that either inform layout behavior or are needed to make layout work at all. These include:

- DesiredSize (actually a UIElement property)
- ActualHeight and ActualWidth
- Height and Width
- Margin
- LayoutUpdated event
- HorizontalAlignment and VerticalAlignment
- ArrangeOverride and MeasureOverride methods
- Arrange and Measure methods: these have native implementations defined at the FrameworkElement level, which handle the element-level layout action

MeasureOverride

The MeasureOverride method has a return value that's used by the layout system as the starting DesiredSize for the panel itself, when the Measure method is called on the panel by its parent in layout. The logic choices within the method are just as important as what it returns, and the logic often influences what value is returned.

All MeasureOverride implementations should loop through Children, and call the Measure method on each child element. Calling the **Measure** method establishes the value for the DesiredSize property. This might inform how much space the panel itself needs, as well as how that space is divided among elements or sized for a particular child element.

Here's a very basic skeleton of a MeasureOverride method:

CSharp

```
protected override Size MeasureOverride(Size availableSize)
{
    Size returnSize; //TODO might return availableSize, might do something
else

    //loop through each Child, call Measure on each
    foreach (UIElement child in Children)
    {
        child.Measure(new Size()); // TODO determine how much space the
panel allots for this child, that's what you pass to Measure
        Size childDesiredSize = child.DesiredSize; //TODO determine how the
returned Size is influenced by each child's DesiredSize
        //TODO, logic if passed-in Size and net DesiredSize are different,
does that matter?
    }
    return returnSize;
}
```

Elements often have a natural size by the time they're ready for layout. After the measure pass, the DesiredSize might indicate that natural size, if the *availableSize* you passed for Measure was smaller. If the natural size is larger than *availableSize* you passed for **Measure**, the **DesiredSize** is constrained to *availableSize*. That's how **Measure**'s internal implementation behaves, and your layout overrides should take that behavior into account.

Some elements don't have a natural size because they have **Auto** values for Height and Width. These elements use the full *availableSize*, because that's what an **Auto** value represents: size the element to the maximum available size, which the immediate layout parent communicates by calling Measure with *availableSize*. In practice, there's always some measurement that a UI is sized to (even if that's the top level window.) Eventually, the measure pass resolves all the **Auto** values to parent constraints and all **Auto** value elements get real measurements (which you can get by checking ActualWidth and ActualHeight, after layout completes).

It's legal to pass a size to Measure that has at least one infinite dimension, to indicate that the panel can attempt to size itself to fit measurements of its content. Each child

element being measured sets its DesiredSize value using its natural size. Then, during the arrange pass, the panel typically arranges using that size.

Text elements such as TextBlock have a calculated ActualWidth and ActualHeight based on their text string and text properties even if no Height or Width value is set, and these dimensions should be respected by your panel logic. Clipping text is a particularly bad UI experience.

Even if your implementation doesn't use the desired size measurements, it's best to call the Measure method on each child element, because there are internal and native behaviors that are triggered by **Measure** being called. For an element to participate in layout, each child element must have **Measure** called on it during the measure pass and the Arrange method called on it during the arrange pass. Calling these methods sets internal flags on the object and populates values (such as the DesiredSize property) that the system's layout logic needs when it builds the visual tree and renders the UI.

The MeasureOverride return value is based on the panel's logic interpreting the DesiredSize or other size considerations for each of the child elements in Children when Measure is called on them. What to do with **DesiredSize** values from children and how the **MeasureOverride** return value should use them is up to your own logic's interpretation. You don't typically add up the values without modification, because the input of **MeasureOverride** is often a fixed available size that's being suggested by the panel's parent. If you exceed that size, the panel itself might get clipped. You'd typically compare the total size of children to the panel's available size and make adjustments if necessary.

Tips and guidance

- Ideally, a custom panel should be suitable for being the first true visual in a UI composition, perhaps at a level immediately under Page, UserControl or another element that is the XAML page root. In MeasureOverride implementations, don't routinely return the input Size without examining the values. If the return **Size** has an **Infinity** value in it, this can throw exceptions in runtime layout logic. An **Infinity** value can come from the main app window, which is scrollable and therefore doesn't have a maximum height. Other scrollable content might have the same behavior.
- Another common mistake in MeasureOverride implementations is to return a new default Size (values for height and width are 0). You might start with that value, and it might even be the correct value if your panel determines that none of the children should be rendered. But, a default **Size** results in your panel not being sized correctly by its host. It requests no space in the UI, and therefore gets no space and doesn't render. All your panel code otherwise might be functioning fine,

but you still won't see your panel or contents thereof if it's being composed with zero height, zero width.

- Within the overrides, avoid the temptation to cast child elements to FrameworkElement and use properties that are calculated as a result of layout, particularly ActualWidth and ActualHeight. For most common scenarios, you can base the logic on the child's DesiredSize value and you won't need any of the Height or Width related properties of a child element. For specialized cases, where you know the type of element and have additional information, for example the natural size of an image file, you can use your element's specialized information because it's not a value that is actively being altered by layout systems. Including layout-calculated properties as part of layout logic substantially increases the risk of defining an unintentional layout loop. These loops cause a condition where a valid layout can't be created and the system can throw a LayoutCycleException if the loop is not recoverable.
- Panels typically divide their available space between multiple child elements, although exactly how space is divided varies. For example, Grid implements layout logic that uses its RowDefinition and ColumnDefinition values to divide the space into the **Grid** cells, supporting both star-sizing and pixel values. If they're pixel values, the size available for each child is already known, so that's what is passed as input size for a grid-style Measure.
- Panels themselves can introduce reserved space for padding between items. If you do this, make sure to expose the measurements as a property that's distinct from Margin or any **Padding** property.
- Elements might have values for their ActualWidth and ActualHeight properties based on a previous layout pass. If values change, app UI code can put handlers for LayoutUpdated on elements if there's special logic to run, but panel logic typically doesn't need to check for changes with event handling. The layout system is already making the determinations of when to re-run layout because a layout-relevant property changed value, and a panel's MeasureOverride or ArrangeOverride are called automatically in the appropriate circumstances.

ArrangeOverride

The ArrangeOverride method has a Size return value that's used by the layout system when rendering the panel itself, when the Arrange method is called on the panel by its parent in layout. It's typical that the input *finalSize* and the **ArrangeOverride** returned **Size** are the same. If they aren't, that means the panel is attempting to make itself a different size than what the other participants in layout claim is available. The final size was based on having previously run the measure pass of layout through your panel

code, so that's why returning a different size isn't typical: it means you are deliberately ignoring measure logic.

Don't return a Size with an **Infinity** component. Trying to use such a **Size** throws an exception from internal layout.

All ArrangeOverride implementations should loop through Children, and call the Arrange method on each child element. Like Measure, **Arrange** doesn't have a return value. Unlike **Measure**, no calculated property gets set as a result (however, the element in question typically fires a LayoutUpdated event).

Here's a very basic skeleton of an ArrangeOverride method:

CSharp

```
protected override Size ArrangeOverride(Size finalSize)
{
    //loop through each Child, call Arrange on each
    foreach (UIElement child in Children)
    {
        Point anchorPoint = new Point(); //TODO more logic for topleft
corner placement in your panel
       // for this child, and based on finalSize or other internal state of
your panel
        child.Arrange(new Rect(anchorPoint, child.DesiredSize)); //OR, set a
different Size
    }
    return finalSize; //OR, return a different Size, but that's rare
}
```

The arrange pass of layout might happen without being preceded by a measure pass. However, this only happens when the layout system has determined no properties have changed that would have affected the previous measurements. For example, if an alignment changes, there's no need to re-measure that particular element because its DesiredSize would not change when its alignment choice changes. On the other hand, if ActualHeight changes on any element in a layout, a new measure pass is needed. The layout system automatically detects true measure changes and invokes the measure pass again, and then runs another arrange pass.

The input for Arrange takes a Rect value. The most common way to construct this **Rect** is to use the constructor that has a Point input and a Size input. The **Point** is the point where the top left corner of the bounding box for the element should be placed. The **Size** is the dimensions used to render that particular element. You often use the DesiredSize for that element as this **Size** value, because establishing the **DesiredSize** for all elements involved in layout was the purpose of the measure pass of layout. (The

measure pass determines all-up sizing of the elements in an iterative way so that the layout system can optimize how elements are placed once it gets to the arrange pass.)

What typically varies between **ArrangeOverride** implementations is the logic by which the panel determines the **Point** component of how it arranges each child. An absolute positioning panel such as **Canvas** uses the explicit placement info that it gets from each element through **Canvas.Left** and **Canvas.Top** values. A space-dividing panel such as **Grid** would have mathematical operations that divided the available space into cells and each cell would have an x-y value for where its content should be placed and arranged. An adaptive panel such as **StackPanel** might be expanding itself to fit content in its orientation dimension.

There are still additional positioning influences on elements in layout, beyond what you directly control and pass to **Arrange**. These come from the internal native implementation of **Arrange** that's common to all **FrameworkElement** derived types and augmented by some other types such as text elements. For example, elements can have margin and alignment, and some can have padding. These properties often interact. For more info, see Alignment, margin, and padding.

Panels and controls

Avoid putting functionality into a custom panel that should instead be built as a custom control. The role of a panel is to present any child element content that exists within it, as a function of layout that happens automatically. The panel might add decorations to content (similar to how a **Border** adds the border around the element it presents), or perform other layout-related adjustments like padding. But that's about as far as you should go when extending the visual tree output beyond reporting and using information from the children.

If there's any interaction that's accessible to the user, you should write a custom control, not a panel. For example, a panel shouldn't add scrolling viewports to content it presents, even if the goal is to prevent clipping, because the scrollbars, thumbs and so on are interactive control parts. (Content might have scrollbars after all, but you should leave that up to the child's logic. Don't force it by adding scrolling as a layout operation.) You might create a control and also write a custom panel that plays an important role in that control's visual tree, when it comes to presenting content in that control. But the control and the panel should be distinct code objects.

One reason the distinction between control and panel is important is because of Microsoft UI Automation and accessibility. Panels provide a visual layout behavior, not a logical behavior. How a UI element appears visually is not an aspect of UI that is typically important to accessibility scenarios. Accessibility is about exposing the parts of an app

that are logically important to understanding a UI. When interaction is required, controls should expose the interaction possibilities to the UI Automation infrastructure. For more info, see Custom automation peers.

Other layout API

There are some other APIs that are part of the layout system, but aren't declared by **Panel**. You might use these in a panel implementation or in a custom control that uses panels.

- **UpdateLayout**, **InvalidateMeasure**, and **InvalidateArrange** are methods that initiate a layout pass. **InvalidateArrange** might not trigger a measure pass, but the other two do. Never call these methods from within a layout method override, because they're almost sure to cause a layout loop. Control code doesn't typically need to call them either. Most aspects of layout are triggered automatically by detecting changes to the framework-defined layout properties such as **Width** and so on.
- **LayoutUpdated** is an event that fires when some aspect of layout of the element has changed. This isn't specific to panels; the event is defined by **FrameworkElement**.
- **SizeChanged** is an event that fires only after layout passes are finalized, and indicates that **ActualHeight** or **ActualWidth** have changed as a result. This is another **FrameworkElement** event. There are cases where **LayoutUpdated** fires, but **SizeChanged** does not. For example the internal contents might be rearranged, but the element's size didn't change.

BoxPanel, an example custom panel

Article • 07/13/2022

Learn to write code for a custom **Panel** class, implementing **ArrangeOverride** and **MeasureOverride** methods, and using the **Children** property.

> **Important APIs**: **Panel**, **ArrangeOverride**,**MeasureOverride**

The example code shows a custom panel implementation, but we don't devote a lot of time explaining the layout concepts that influence how you can customize a panel for different layout scenarios. If you want more info about these layout concepts and how they might apply to your particular layout scenario, see XAML custom panels overview.

A *panel* is an object that provides a layout behavior for child elements it contains, when the XAML layout system runs and your app UI is rendered. You can define custom panels for XAML layout by deriving a custom class from the **Panel** class. You provide behavior for your panel by overriding the **ArrangeOverride** and **MeasureOverride** methods, supplying logic that measures and arranges the child elements. This example derives from **Panel**. When you start from **Panel**, **ArrangeOverride** and **MeasureOverride** methods don't have a starting behavior. Your code is providing the gateway by which child elements become known to the XAML layout system and get rendered in the UI. So, it's really important that your code accounts for all child elements and follows the patterns the layout system expects.

Your layout scenario

When you define a custom panel, you're defining a layout scenario.

A layout scenario is expressed through:

- What the panel will do when it has child elements
- When the panel has constraints on its own space
- How the logic of the panel determines all the measurements, placement, positions, and sizings that eventually result in a rendered UI layout of children

With that in mind, the `BoxPanel` shown here is for a particular scenario. In the interest of keeping the code foremost in this example, we won't explain the scenario in detail yet, and instead concentrate on the steps needed and the coding patterns. If you want to know more about the scenario first, skip ahead to "The scenario for BoxPanel", and then come back to the code.

Start by deriving from Panel

Start by deriving a custom class from **Panel**. Probably the easiest way to do this is to define a separate code file for this class, using the **Add** | **New Item** | **Class** context menu options for a project from the **Solution Explorer** in Microsoft Visual Studio. Name the class (and file) `BoxPanel`.

The template file for a class doesn't start with many **using** statements because it's not specifically for Windows apps. So first, add **using** statements. The template file also starts with a few **using** statements that you probably don't need, and can be deleted. Here's a suggested list of **using** statements that can resolve types you'll need for typical custom panel code:

CSharp

```
using System;
using System.Collections.Generic; // if you need to cast IEnumerable for
iteration, or define your own collection properties
using Windows.Foundation; // Point, Size, and Rect
using Windows.UI.Xaml; // DependencyObject, UIElement, and FrameworkElement
using Windows.UI.Xaml.Controls; // Panel
using Windows.UI.Xaml.Media; // if you need Brushes or other utilities
```

Now that you can resolve **Panel**, make it the base class of `BoxPanel`. Also, make `BoxPanel` public:

CSharp

```
public class BoxPanel : Panel
{
}
```

At the class level, define some **int** and **double** values that will be shared by several of your logic functions, but which won't need to be exposed as public API. In the example, these are named: `maxrc`, `rowcount`, `colcount`, `cellwidth`, `cellheight`, `maxcellheight`, `aspectratio`.

After you've done this, the complete code file looks like this (removing comments on **using**, now that you know why we have them):

CSharp

```
using System;
using System.Collections.Generic;
using Windows.Foundation;
```

```
using Windows.UI.Xaml;
using Windows.UI.Xaml.Controls;
using Windows.UI.Xaml.Media;

public class BoxPanel : Panel
{
    int maxrc, rowcount, colcount;
    double cellwidth, cellheight, maxcellheight, aspectratio;
}
```

From here on out, we'll be showing you one member definition at a time, be that a method override or something supporting such as a dependency property. You can add these to the skeleton above in any order.

MeasureOverride

CSharp

```
protected override Size MeasureOverride(Size availableSize)
{
    // Determine the square that can contain this number of items.
    maxrc = (int)Math.Ceiling(Math.Sqrt(Children.Count));
    // Get an aspect ratio from availableSize, decides whether to trim row
or column.
    aspectratio = availableSize.Width / availableSize.Height;

    // Now trim this square down to a rect, many times an entire row or
column can be omitted.
    if (aspectratio > 1)
    {
        rowcount = maxrc;
        colcount = (maxrc > 2 && Children.Count <= maxrc * (maxrc - 1)) ?
maxrc - 1 : maxrc;
    }
    else
    {
        rowcount = (maxrc > 2 && Children.Count <= maxrc * (maxrc - 1)) ?
maxrc - 1 : maxrc;
        colcount = maxrc;
    }

    // Now that we have a column count, divide available horizontal, that's
our cell width.
    cellwidth = (int)Math.Floor(availableSize.Width / colcount);
    // Next get a cell height, same logic of dividing available vertical by
rowcount.
    cellheight = Double.IsInfinity(availableSize.Height) ?
Double.PositiveInfinity : availableSize.Height / rowcount;

    foreach (UIElement child in Children)
    {
```

```
            child.Measure(new Size(cellwidth, cellheight));
            maxcellheight = (child.DesiredSize.Height > maxcellheight) ?
child.DesiredSize.Height : maxcellheight;
        }
        return LimitUnboundedSize(availableSize);
}
```

The necessary pattern of a MeasureOverride implementation is the loop through each element in Panel.Children. Always call the Measure method on each of these elements. **Measure** has a parameter of type Size. What you're passing here is the size that your panel is committing to have available for that particular child element. So, before you can do the loop and start calling **Measure**, you need to know how much space each cell can devote. From the **MeasureOverride** method itself, you have the *availableSize* value. That is the size that the panel's parent used when it called **Measure**, which was the trigger for this **MeasureOverride** being called in the first place. So a typical logic is to devise a scheme whereby each child element divides the space of the panel's overall *availableSize*. You then pass each division of size to **Measure** of each child element.

How `BoxPanel` divides size is fairly simple: it divides its space into a number of boxes that's largely controlled by the number of items. Boxes are sized based on row and column count and the available size. Sometimes one row or column from a square isn't needed, so it's dropped and the panel becomes a rectangle rather than square in terms of its row : column ratio. For more info about how this logic was arrived at, skip ahead to "The scenario for BoxPanel".

So what does the measure pass do? It sets a value for the read-only DesiredSize property on each element where Measure was called. Having a **DesiredSize** value is possibly important once you get to the arrange pass, because the **DesiredSize** communicates what the size can or should be when arranging and in the final rendering. Even if you don't use **DesiredSize** in your own logic, the system still needs it.

It's possible for this panel to be used when the height component of *availableSize* is unbounded. If that's true, the panel doesn't have a known height to divide. In this case, the logic for the measure pass informs each child that it doesn't have a bounded height, yet. It does so by passing a Size to the Measure call for children where Size.Height is infinite. That's legal. When **Measure** is called, the logic is that the DesiredSize is set as the minimum of these: what was passed to **Measure**, or that element's natural size from factors such as explicitly-set Height and Width.

> ⓘ **Note**
>
> The internal logic of StackPanel also has this behavior: **StackPanel** passes an infinite dimension value to Measure on children, indicating that there is no constraint on

children in the orientation dimension. **StackPanel** typically sizes itself dynamically, to accommodate all children in a stack that grows in that dimension.

However, the panel itself can't return a **Size** with an infinite value from **MeasureOverride**; that throws an exception during layout. So, part of the logic is to find out the maximum height that any child requests, and use that height as the cell height in case that isn't coming from the panel's own size constraints already. Here's the helper function `LimitUnboundedSize` that was referenced in previous code, which then takes that maximum cell height and uses it to give the panel a finite height to return, as well as assuring that `cellheight` is a finite number before the arrange pass is initiated:

CSharp

```
// This method limits the panel height when no limit is imposed by the
panel's parent.
// That can happen to height if the panel is close to the root of main app
window.
// In this case, base the height of a cell on the max height from desired
size
// and base the height of the panel on that number times the #rows.
Size LimitUnboundedSize(Size input)
{
    if (Double.IsInfinity(input.Height))
    {
        input.Height = maxcellheight * colcount;
        cellheight = maxcellheight;
    }
    return input;
}
```

ArrangeOverride

CSharp

```
protected override Size ArrangeOverride(Size finalSize)
{
     int count = 1;
     double x, y;
     foreach (UIElement child in Children)
     {
          x = (count - 1) % colcount * cellwidth;
          y = ((int)(count - 1) / colcount) * cellheight;
          Point anchorPoint = new Point(x, y);
          child.Arrange(new Rect(anchorPoint, child.DesiredSize));
          count++;
     }
```

```
        return finalSize;
    }
```

The necessary pattern of an ArrangeOverride implementation is the loop through each element in Panel.Children. Always call the Arrange method on each of these elements.

Note how there aren't as many calculations as in MeasureOverride; that's typical. The size of children is already known from the panel's own **MeasureOverride** logic, or from the DesiredSize value of each child set during the measure pass. However, we still need to decide the location within the panel where each child will appear. In a typical panel, each child should render at a different position. A panel that creates overlapping elements isn't desirable for typical scenarios (although it's not out of the question to create panels that have purposeful overlaps, if that's really your intended scenario).

This panel arranges by the concept of rows and columns. The number of rows and columns was already calculated (it was necessary for measurement). So now the shape of the rows and columns plus the known sizes of each cell contribute to the logic of defining a rendering position (the `anchorPoint`) for each element that this panel contains. That Point, along with the Size already known from measure, are used as the two components that construct a Rect. **Rect** is the input type for Arrange.

Panels sometimes need to clip their content. If they do, the clipped size is the size that's present in DesiredSize, because the Measure logic sets it as the minimum of what was passed to **Measure**, or other natural size factors. So you don't typically need to specifically check for clipping during Arrange; the clipping just happens based on passing the **DesiredSize** through to each **Arrange** call.

You don't always need a count while going through the loop if all the info you need for defining the rendering position is known by other means. For example, in Canvas layout logic, the position in the Children collection doesn't matter. All the info needed to position each element in a **Canvas** is known by reading Canvas.Left and Canvas.Top values of children as part of the arrange logic. The `BoxPanel` logic happens to need a count to compare to the *colcount* so it's known when to begin a new row and offset the *y* value.

It's typical that the input *finalSize* and the Size you return from a ArrangeOverride implementation are the same. For more info about why, see "**ArrangeOverride**" section of XAML custom panels overview.

A refinement: controlling the row vs. column count

You could compile and use this panel just as it is now. However, we'll add one more refinement. In the code just shown, the logic puts the extra row or column on the side that's longest in aspect ratio. But for greater control over the shapes of cells, it might be desirable to choose a 4x3 set of cells instead of 3x4 even if the panel's own aspect ratio is "portrait." So we'll add an optional dependency property that the panel consumer can set to control that behavior. Here's the dependency property definition, which is very basic:

CSharp

```
// Property
public Orientation Orientation
{
    get { return (Orientation)GetValue(OrientationProperty); }
    set { SetValue(OrientationProperty, value); }
}

// Dependency Property Registration
public static readonly DependencyProperty OrientationProperty =
        DependencyProperty.Register(nameof(Orientation),
typeof(Orientation), typeof(BoxPanel), new PropertyMetadata(null,
OnOrientationChanged));

// Changed callback so we invalidate our layout when the property changes.
private static void OnOrientationChanged(DependencyObject dependencyObject,
DependencyPropertyChangedEventArgs args)
{
    if (dependencyObject is BoxPanel panel)
    {
        panel.InvalidateMeasure();
    }
}
```

And below is how using `Orientation` impacts the measure logic in `MeasureOverride`. Really all it's doing is changing how `rowcount` and `colcount` are derived from `maxrc` and the true aspect ratio, and there are corresponding size differences for each cell because of that. When `Orientation` is **Vertical** (default), it inverts the value of the true aspect ratio before using it for row and column counts for our "portrait" rectangle layout.

CSharp

```
// Get an aspect ratio from availableSize, decides whether to trim row or
column.
aspectratio = availableSize.Width / availableSize.Height;

// Transpose aspect ratio based on Orientation property.
if (Orientation == Orientation.Vertical) { aspectratio = 1 / aspectratio; }
```

The scenario for BoxPanel

The particular scenario for `BoxPanel` is that it's a panel where one of the main determinants of how to divide space is by knowing the number of child items, and dividing the known available space for the panel. Panels are innately rectangle shapes. Many panels operate by dividing that rectangle space into further rectangles; that's what **Grid** does for its cells. In **Grid**'s case, the size of the cells is set by **ColumnDefinition** and **RowDefinition** values, and elements declare the exact cell they go into with **Grid.Row** and **Grid.Column** attached properties. Getting good layout from a **Grid** usually requires knowing the number of child elements beforehand, so that there are enough cells and each child element sets its attached properties to fit into its own cell.

But what if the number of children is dynamic? That's certainly possible; your app code can add items to collections, in response to any dynamic run-time condition you consider to be important enough to be worth updating your UI. If you're using data binding to backing collections/business objects, getting such updates and updating the UI is handled automatically, so that's often the preferred technique (see Data binding in depth).

But not all app scenarios lend themselves to data binding. Sometimes, you need to create new UI elements at runtime and make them visible. `BoxPanel` is for this scenario. A changing number of child items is no problem for `BoxPanel` because it's using the child count in calculations, and adjusts both the existing and new child elements into a new layout so they all fit.

An advanced scenario for extending `BoxPanel` further (not shown here) could both accommodate dynamic children and use a child's **DesiredSize** as a stronger factor for the sizing of individual cells. This scenario might use varying row or column sizes or non-grid shapes so that there's less "wasted" space. This requires a strategy for how multiple rectangles of various sizes and aspect ratios can all fit into a containing rectangle both for aesthetics and smallest size. `BoxPanel` doesn't do that; it's using a simpler technique for dividing space. `BoxPanel`'s technique is to determine the least square number that's greater than the child count. For example, 9 items would fit in a 3x3 square. 10 items require a 4x4 square. However, you can often fit items while still removing one row or column of the starting square, to save space. In the count=10 example, that fits in a 4x3 or 3x4 rectangle.

You might wonder why the panel wouldn't instead choose 5x2 for 10 items, because that fits the item number neatly. However, in practice, panels are sized as rectangles that seldom have a strongly oriented aspect ratio. The least-squares technique is a way to

bias the sizing logic to work well with typical layout shapes and not encourage sizing where the cell shapes get odd aspect ratios.

Attached Layouts

Article • 05/26/2022

A container (for example, Panel) that delegates its layout logic to another object relies on the attached layout object to provide the layout behavior for its child elements. An attached layout model provides flexibility for an application to alter the layout of items at runtime, or more easily share aspects of layout between different parts of the UI (for example, items in the rows of a table that appear to be aligned within a column).

In this topic, we cover what's involved in creating an attached layout (virtualizing and non-virtualizing), the concepts and classes you'll need to understand, and the trade-offs you'll need to consider when deciding between them.

> - LayoutPanel (Preview)

Key Concepts

Performing layout requires that two questions be answered for every element:

1. What ***size*** will this element be?
2. What will the ***position*** of this element be?

XAML's layout system, which answers these questions, is briefly covered as part of the discussion of Custom panels.

Containers and Context

Conceptually, XAML's Panel fills two important roles in the framework:

1. It can contain child elements and introduces branching in the tree of elements.
2. It applies a specific layout strategy to those children.

For this reason, a Panel in XAML has often been synonymous with layout, but technically-speaking, does more than just layout.

The ItemsRepeater also behaves like Panel, but, unlike Panel, it does not expose a Children property that would allow programmatically adding or removing UIElement children. Instead, the lifetime of its children are automatically managed by the framework to correspond to a collection of data items. Although it is not derived from Panel, it behaves and is treated by the framework like a Panel.

> **Note**
>
> The **LayoutPanel** is a container, derived from Panel, that delegates its logic to the attached **Layout** object. LayoutPanel is in *Preview* and is currently available only in the *Prerelease* drops of the WinUI package.

Containers

Conceptually, Panel is a container of elements that also has the ability to render pixels for a Background. Panels provide a way to encapsulate common layout logic in an easy to use package.

The concept of **attached layout** makes the distinction between the two roles of container and layout more clear. If the container delegates its layout logic to another object we would call that object the attached layout as seen in the snippet below. Containers that inherit from FrameworkElement, such as the LayoutPanel, automatically expose the common properties that provide input to XAML's layout process (for example, Height and Width).

XAML

```
<LayoutPanel>
    <LayoutPanel.Layout>
        <UniformGridLayout/>
```

```
    </LayoutPanel.Layout>
    <Button Content="1"/>
    <Button Content="2"/>
    <Button Content="3"/>
</LayoutPanel>
```

During the layout process the container relies on the attached *UniformGridLayout* to measure and arrange its children.

Per-Container State

With an attached layout, a single instance of the layout object may be associated with *many* containers like in the snippet below; therefore, it must not depend on or directly reference the host container. For example:

XAML

```
<!-- ... --->
<Page.Resources>
    <ExampleLayout x:Name="exampleLayout"/>
<Page.Resources>

<LayoutPanel x:Name="example1" Layout="{StaticResource exampleLayout}"/>
<LayoutPanel x:Name="example2" Layout="{StaticResource exampleLayout}"/>
<!-- ... --->
```

For this situation *ExampleLayout* must carefully consider the state that it uses in its layout calculation and where that state is stored to avoid impacting the layout for elements in one panel with the other. It would be analogous to a custom Panel whose MeasureOverride and ArrangeOverride logic depends on the values of its *static* properties.

LayoutContext

The purpose of the LayoutContext is to deal with those challenges. It provides the attached layout the ability to interact with the host container, such as retrieving child elements, without introducing a direct dependency between the two. The context also enables the layout to store any state it requires that might be related to the container's child elements.

Simple, non-virtualizing layouts often do not need to maintain any state, making it a non-issue. A more complex layout, such as Grid, however, may choose to maintain state between the measure and arrange call to avoid re-computing a value.

Virtualizing layouts *often* need to maintain some state between both the measure and arrange as well as between iterative layout passes.

Initializing and Uninitializing Per-Container State

When a layout is attached to a container, its InitializeForContextCore method is called and provides an opportunity to initialize an object to store state.

Similarly, when the layout is being removed from a container, the UninitializeForContextCore method will be called. This gives the layout an opportunity to clean up any state it had associated with that container.

The layout's state object can be stored with and retrieved from the container with the LayoutState property on the context.

UI Virtualization

UI virtualization means delaying the creation of a UI object until *when it's needed*. It's a performance optimization. For non-scrolling scenarios determining *when needed* may be based on any number of things that are app-specific. In those cases, apps should consider using the x:Load. It does not require any special handling in your layout.

In scrolling-based scenarios such as a list, determining *when needed* is often based on "will it be visible to a user" which depends heavily on where it was placed during the layout process and requires special considerations. This scenario is a focus for this document.

> ⓘ **Note**
>
> Although not covered in this document, the same capabilities that enable UI virtualization in scrolling scenarios could be applied in non-scrolling scenarios. For example, a data-driven ToolBar control that manages the lifetime of the commands it presents and responds to changes in available space by recycling / moving elements between a visible area and an overflow menu.

Getting Started

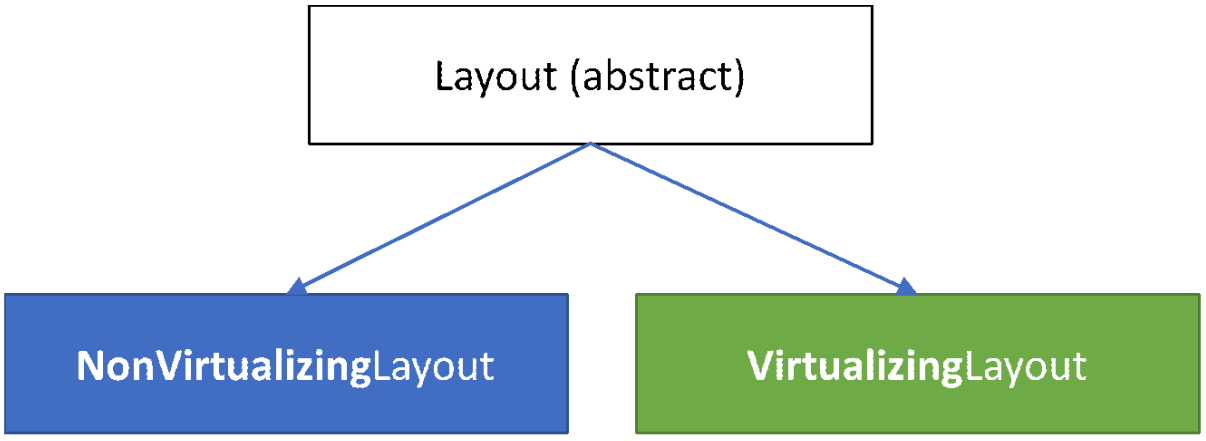
First, decide whether the layout you need to create should support UI virtualization.

A few things to keep in mind...

1. Non-virtualizing layouts are easier to author. If the number of items will always be small then authoring a non-virtualizing layout is recommended.
2. The platform provides a set of attached layouts that work with the ItemsRepeater and LayoutPanel to cover common needs. Familiarize yourself with those before deciding you need to define a custom layout.
3. Virtualizing layouts always have some additional CPU and memory cost/complexity/overhead compared to a non-virtualizing layout. As a general rule of thumb if the children the layout will need to manage will likely fit in an area that is 3x the size of the viewport, then there may not be much gain from a virtualizing layout. The 3x size is discussed in greater detail later in this doc, but is due to the asynchronous nature of scrolling on Windows and its impact on virtualization.

> **Tip**
>
> As a point of reference, the default settings for the **ListView** (and **ItemsRepeater**) are that recycling doesn't begin until the number of items are enough to fill up 3x the size of the current viewport.

Choose your base type



The base Layout type has two derived types that serve as the start point for authoring an attached layout:

1. NonVirtualizingLayout
2. VirtualizingLayout

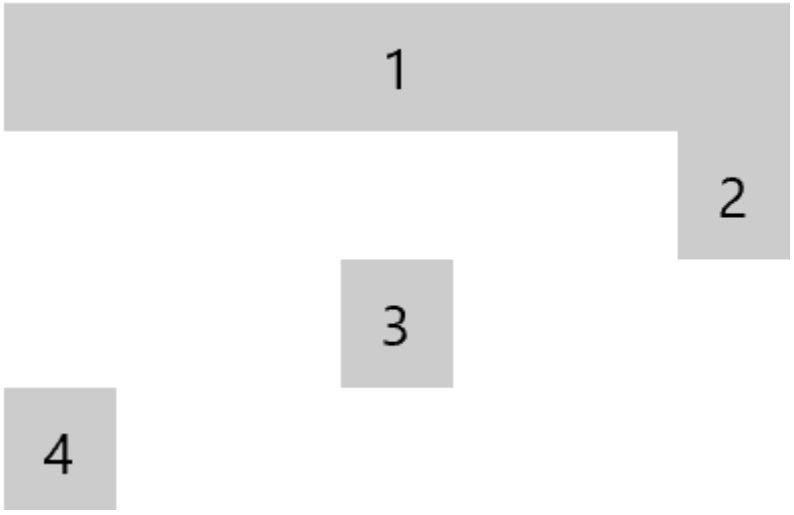
Non-Virtualizing Layout

The approach for creating a non-virtualizing layout should feel familiar to anyone that has created a Custom Panel. The same concepts apply. The primary difference is that a

NonVirtualizingLayoutContext is used to access the Children collection, and layout may choose to store state.

1. Derive from the base type NonVirtualizingLayout (instead of Panel).
2. *(Optional)* Define dependency properties that when changed will invalidate the layout.
3. ***(New**/Optional)* Initialize any state object required by the layout as part of the InitializeForContextCore. Stash it with the host container by using the LayoutState provided with the context.
4. Override the MeasureOverride and call the Measure method on all the children.
5. Override the ArrangeOverride and call the Arrange method on all the children.
6. ***(New**/Optional)* Clean up any saved state as part of the UninitializeForContextCore.

Example: A Simple Stack Layout (Varying-Sized Items)



Here is a very basic non-virtualizing stack layout of varying sized items. It lacks any properties to adjust the layout's behavior. The implementation below illustrates how the layout relies on the context object provided by the container to:

1. Get the count of children, and
2. Access each child element by index.

C#

```
public class MyStackLayout : NonVirtualizingLayout
{
    protected override Size MeasureOverride(NonVirtualizingLayoutContext
context, Size availableSize)
    {
        double extentHeight = 0.0;
        foreach (var element in context.Children)
        {
            element.Measure(availableSize);
```

```
            extentHeight += element.DesiredSize.Height;
        }

        return new Size(availableSize.Width, extentHeight);
    }

    protected override Size ArrangeOverride(NonVirtualizingLayoutContext
context, Size finalSize)
    {
        double offset = 0.0;
        foreach (var element in context.Children)
        {
            element.Arrange(
                new Rect(0, offset, finalSize.Width,
element.DesiredSize.Height));
            offset += element.DesiredSize.Height;
        }

        return finalSize;
    }
}
```

XAML

```
 <LayoutPanel MaxWidth="196">
    <LayoutPanel.Layout>
        <local:MyStackLayout/>
    </LayoutPanel.Layout>

    <Button HorizontalAlignment="Stretch">1</Button>
    <Button HorizontalAlignment="Right">2</Button>
    <Button HorizontalAlignment="Center">3</Button>
    <Button>4</Button>

</LayoutPanel>
```

Virtualizing Layouts

Similar to a non-virtualizing layout, the high-level steps for a virtualizing layout are the same. The complexity is largely in determining what elements will fall within the viewport and should be realized.

1. Derive from the base type VirtualizingLayout.
2. (Optional) Define your dependency properties that when changed will invalidate the layout.
3. Initialize any state object that will be required by the layout as part of the InitializeForContextCore. Stash it with the host container by using the LayoutState provided with the context.

4. Override the MeasureOverride and call the Measure method for each child that should be realized.
    a. The GetOrCreateElementAt method is used to retrieve a UIElement that has been prepared by the framework (for example, data bindings applied).
5. Override the ArrangeOverride and call the Arrange method for each realized child.
6. (Optional) Clean up any saved state as part of the UninitializeForContextCore.

> **Tip**
>
> The value returned by the **MeasureOverride** is used as the size of the virtualized content.

There are two general approaches to consider when authoring a virtualizing layout. Whether to choose one or the other largely depends on "how will you determine the size of an element". If its enough to know the index of an item in the data set or the data itself dictates its eventual size, then we'd consider it **data-dependent**. These are more straightforward to create. If, however, the only way to determine the size for an item is to create and measure the UI then we'd say it is **content-dependent**. These are more complex.

The Layout Process

Whether you're creating a data or content-dependent layout, it's important to understand the layout process and the impact of Windows' asynchronous scrolling.

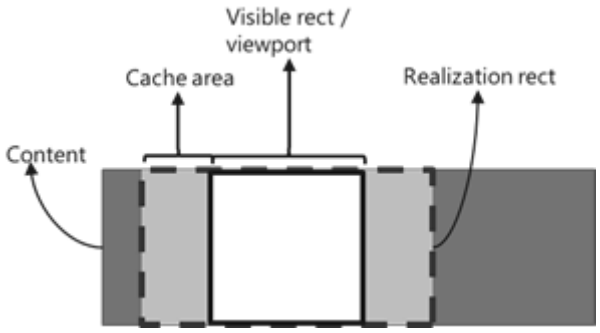
An (over)simplified view of the steps performed by the framework from start-up to displaying UI on screen is that:

1. It parses the markup.
2. Generates a tree of elements.
3. Performs a layout pass.
4. Performs a render pass.

With UI virtualization, creating the elements that would normally be done in step 2 is delayed or ended early once its been determined that sufficient content has been created to fill the viewport. A virtualizing container (for example, ItemsRepeater) defers to its attached layout to drive this process. It provides the attached layout with a VirtualizingLayoutContext that surfaces the additional information that a virtualizing layout needs.

The RealizationRect (i.e. Viewport)

Scrolling on Windows happens asynchronous to the UI thread. It is not controlled by the framework's layout. Rather, the interaction and movement occurs in the system's compositor. The advantage of this approach is that panning content can always be done at 60fps. The challenge, however, is that the "viewport", as seen by the layout, might be slightly out-of-date relative to what is actually visible on screen. If a user scrolls quickly, they may outpace the speed of the UI thread to generate new content and "pan to black". For this reason, it's often necessary for a virtualizing layout to generate an additional buffer of prepared elements sufficient to fill an area larger than the viewport. When under heavier load during scrolling the user is still presented with content.



Since element creation is costly, virtualizing containers (for example, ItemsRepeater) will initially provide the attached layout with a RealizationRect that matches the viewport. On idle time the container may grow the buffer of prepared content by making repeated calls to the layout using an increasingly larger realization rect. This behavior is a performance optimization that attempts to strike a balance between fast startup time and a good panning experience. The maximum buffer size that the ItemsRepeater will generate is controlled by its VerticalCacheLength and HorizontalCacheLength properties.

Re-using Elements (Recycling)

The layout is expected to size and position the elements to fill the RealizationRect each time it is run. By default the VirtualizingLayout will recycle any unused elements at the end of each layout pass.

The VirtualizingLayoutContext that is passed to the layout as part of the MeasureOverride and ArrangeOverride provides the additional information a virtualizing layout needs. Some of the most commonly used things it provides are the ability to:

1. Query the number of items in the data (ItemCount).
2. Retrieve a specific item using the GetItemAt method.
3. Retrieve a RealizationRect that represents the viewport and buffer that the layout should fill with realized elements.
4. Request the UIElement for a specific item with the GetOrCreateElement method.

Requesting an element for a given index will cause that element to be marked as "in use" for that pass of the layout. If the element does not already exist, then it will be realized and automatically prepared for use (for example, inflating the UI tree defined in a DataTemplate, processing any data binding, etc.). Otherwise, it will be retrieved from a pool of existing instances.

At the end of each measure pass, any existing, realized element that was not marked "in use" is automatically considered available for re-use unless the option to SuppressAutoRecycle was used when the element was retrieved via the GetOrCreateElementAt method. The framework automatically moves it to a recycle pool and makes it available. It may subsequently be pulled for use by a different container. The framework tries to avoid this when possible as there is some cost associated with re-parenting an element.

If a virtualizing layout knows at the beginning of each measure which elements will no longer fall within the realization rect then it can optimize its re-use. Rather than relying on the framework's default behavior. The layout can preemptively move elements to the recycle pool by using the RecycleElement method. Calling this method before requesting new elements causes those existing elements to be available when the layout later issues a GetOrCreateElementAt request for an index that isn't already associated with an element.

The VirtualizingLayoutContext provides two additional properties designed for layout authors creating a content-dependent layout. They are discussed in more detail later.

1. A RecommendedAnchorIndex that provides an optional *input* to layout.
2. A LayoutOrigin that is an optional *output* of the layout.

Data-dependent Virtualizing Layouts

A virtualizing layout is easier if you know what the size of every item should be without needing to measure the content to show. In this doc we'll simply refer to this category of virtualizing layouts as **data layouts** since they usually involve inspecting the data. Based on the data an app may pick a visual representation with a known size - perhaps because its part of the data or was previously determined by design.

The general approach is for the layout to:

1. Calculate a size and position of every item.
2. As part of the MeasureOverride:
    a. Use the RealizationRect to determine which items should appear within the viewport.

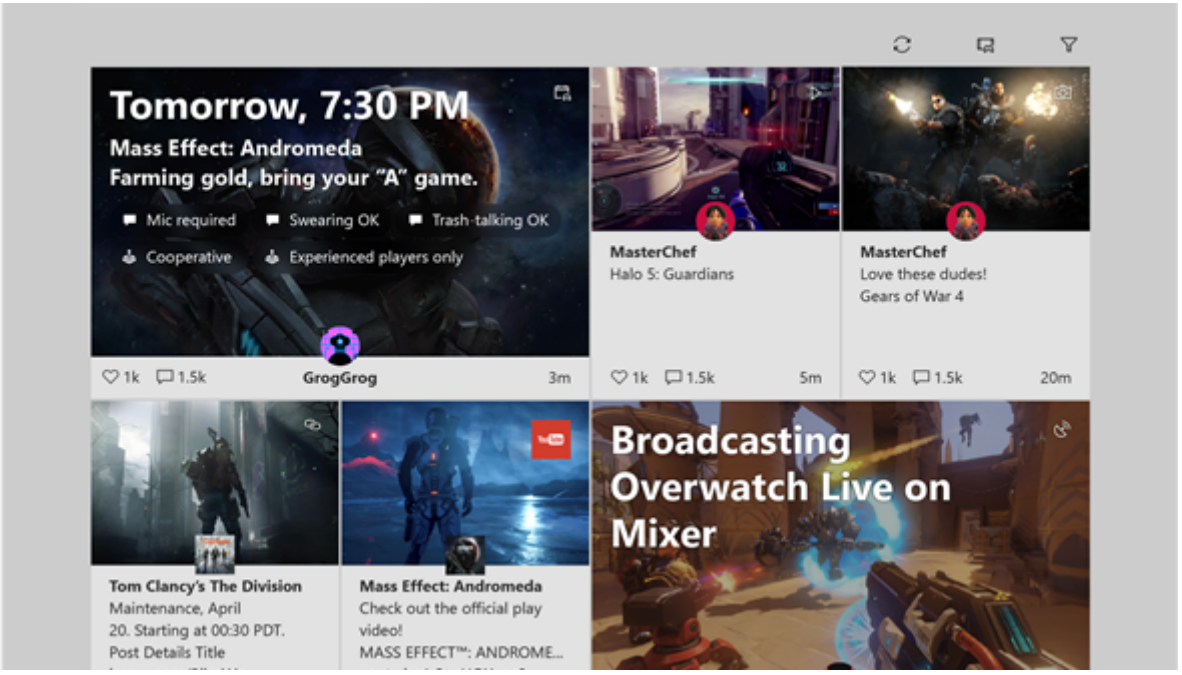
    b. Retrieve the UIElement that should represent the item with the GetOrCreateElementAt method.
    c. Measure the UIElement with the pre-calculated size.
3. As part of the ArrangeOverride, Arrange each realized UIElement with the precalculated position.

> **Note**
>
> A data layout approach is often incompatible with *data virtualization*. Specifically, where the only data loaded into memory is that data required to fill what's visible to the user. Data virtualization isn't referring to lazy or incremental loading of data as a user scrolls down where that data remains resident. Rather, it's referring to when items are released from memory as they're scrolled out of view. Having a data layout that inspects every data item as part of a data layout would prevent data virtualization from working as expected. An exception is a layout like the UniformGridLayout which assumes that everything has the same size.

> **Tip**
>
> If you're creating a custom control for a control library that will be used by others in a wide variety of situations then a data layout may not be an option for you.

Example: Xbox Activity Feed layout

The UI for the Xbox Activity Feed uses a repeating pattern where each line has a wide tile, followed by two narrow tiles that is inverted on the subsequent line. In this layout, the size for every item is a function of the item's position in the data set and the known size for the tiles (wide vs narrow).



The code below walks through what a custom virtualizing UI for the activity feed might be to illustrate the general approach you might take for a **data layout**.

> **Tip**
>
> If you have the **WinUI 3 Gallery** app installed, click here to **open the app and see the ItemsRepeater in action**. Get the app from the **Microsoft Store** or get the source code on **GitHub**.

Implementation

C#

```
/// <summary>
///  This is a custom layout that displays elements in two different sizes
///  wide (w) and narrow (n). There are two types of rows
///  odd rows - narrow narrow wide
///  even rows - wide narrow narrow
///  This pattern repeats.
/// </summary>

public class ActivityFeedLayout : VirtualizingLayout // STEP #1 Inherit from
base attached layout

```

(Optional) Managing the Item to UIElement Mapping

By default, the VirtualizingLayoutContext maintains a mapping between the realized elements and the index in the data source they represent. A layout can choose to manage this mapping itself by always requesting the option to SuppressAutoRecycle when retrieving an element via the GetOrCreateElementAt method which prevents the default auto-recycling behavior. A layout may choose to do this, for example, if it will only be used when scrolling is restricted to one direction and the items it considers will always be contiguous (i.e. knowing the index of the first and last element is enough to know all the elements that should be realized).

Example: Xbox Activity Feed measure

The snippet below shows the additional logic that could be added to the MeasureOverride in the previous sample to manage the mapping.

C#

```
    protected override Size MeasureOverride(VirtualizingLayoutContext
context, Size availableSize)
    {
        //...

        // Determine which items will appear on those rows and what the rect
will be for each item
        var state = context.LayoutState as ActivityFeedLayoutState;
        state.LayoutRects.Clear();

         // Recycle previously realized elements that we know we won't need
so that they can be used to
```

```
        // fill in gaps without requiring us to realize additional elements.
        var newFirstRealizedIndex = firstRowIndex * 3;
        var newLastRealizedIndex = lastRowIndex * 3 + 3;
        for (int i = state.FirstRealizedIndex; i < newFirstRealizedIndex;
i++)
        {
            context.RecycleElement(state.IndexToElementMap.Get(i));
            state.IndexToElementMap.Clear(i);
        }

        for (int i = state.LastRealizedIndex; i < newLastRealizedIndex; i++)
        {
            context.RecycleElement(context.IndexElementMap.Get(i));
            state.IndexToElementMap.Clear(i);
        }

        // ...

        // Foreach item between the first and last index,
        //     Call GetElementOrCreateElementAt which causes an element to
either be realized or retrieved
        //       from a recycle pool
        //     Measure the element using an appropriate size
        //
        for (int rowIndex = firstRowIndex; rowIndex < lastRowIndex;
rowIndex++)
        {
            int firstItemIndex = rowIndex * 3;
            var boundsForCurrentRow = CalculateLayoutBoundsForRow(rowIndex,
desiredItemWidth);

            for (int columnIndex = 0; columnIndex < 3; columnIndex++)
            {

Content-dependent Virtualizing Layouts

If you must first measure the UI content for an item to figure out its exact size then it is a **content-dependent layout**. You can also think of it as a layout where each item must size itself rather than the layout telling the item its size. Virtualizing layouts that fall into this category are more involved.

> ⓘ Note
>
> Content-dependent layouts don't (shouldn't) break data virtualization.

Estimations

Content-dependent layouts rely on estimation to guess both the size of unrealized content and the position of the realized content. As those estimates change it will cause the realized content to regularly shift positions within the scrollable area. This can lead to a very frustrating and jarring user experience if not mitigated. The potential issues and mitigations are discussed here.

> ⓘ Note
>
> Data layouts that consider every item and know the exact size of all items, realized or not, and their positions can avoid these issues entirely.

Scroll Anchoring

XAML provides a mechanism to mitigate sudden viewport shifts by having scrolling controls support scroll anchoring by implementing the IScrollAnchorPovider interface. As the user manipulates the content, the scrolling control continually selects an element from the set of candidates that were opted-in to be tracked. If the position of the

anchor element shifts during the layout then the scroll control automatically shifts its viewport to maintain the viewport.

The value of the RecommendedAnchorIndex provided to the layout may reflect that currently selected anchor element chosen by the scrolling control. Alternatively, if a developer explicitly requests that an element be realized for an index with the GetOrCreateElement method on the ItemsRepeater, then that index is given as the RecommendedAnchorIndex on the next layout pass. This enables the layout to be prepared for the likely scenario that a developer realizes an element and subsequently requests that it be brought into view via the StartBringIntoView method.

The RecommendedAnchorIndex is the index for the item in the data source that a content-dependent layout should position first when estimating the position of its items. It should serve as the starting point for positioning other realized items.

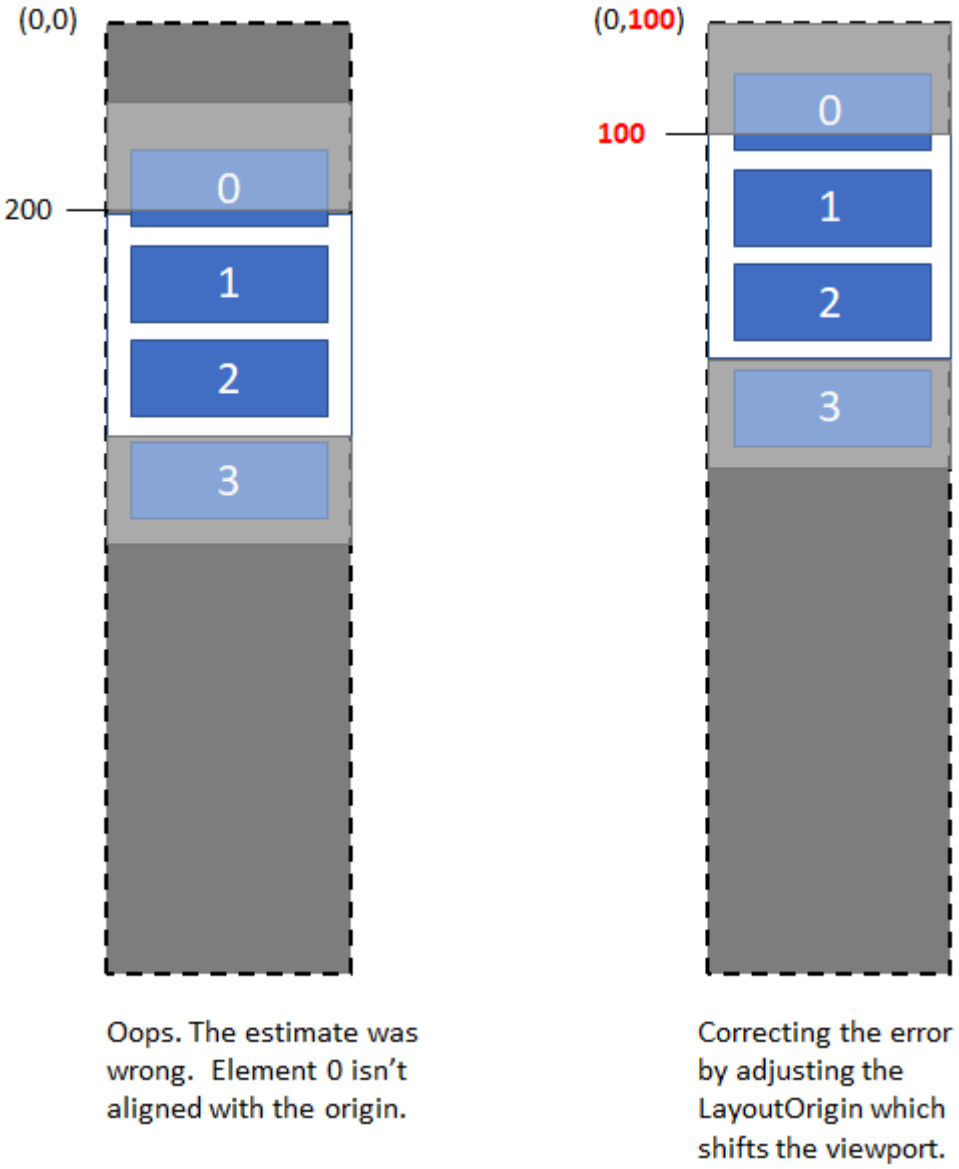
Impact on ScrollBars

Even with scroll anchoring, if the layout's estimates vary a lot, perhaps due to significant variations in the size of content, then the position of the thumb for the ScrollBar may appear to jump around. This can be jarring for a user if the thumb doesn't appear to track the position of their mouse pointer when they're dragging it.

The more accurate the layout can be in its estimations then the less likely a user will see the ScrollBar's thumb jumping.

Layout Corrections

A content-dependent layout should be prepared to rationalize its estimate with reality. For example, as the user scrolls to the top of the content and the layout realizes the very first element, it may find that the element's anticipated position relative to the element from which it started would cause it to appear somewhere other than the origin of (x:0, y:0). When this occurs, the layout can use the LayoutOrigin property to set the position it calculated as the new layout origin. The net result is similar to scroll anchoring in which the scrolling control's viewport is automatically adjusted to account for the content's position as reported by the layout.



Disconnected Viewports

The size returned from the layout's MeasureOverride method represents the best guess at the size of the content which may change with each successive layout. As a user scrolls the layout will be continually re-evaluated with an updated RealizationRect.

If a user drags the thumb very quickly then its possible for the viewport, from the perspective of the layout, to appear to make large jumps where the prior position doesn't overlap the now current position. This is due to the asynchronous nature of scrolling. It's also possible for an app that is consuming the layout to request that an element be brought into view for an item that is not currently realized and is estimated to lay outside the current range tracked by the layout.

When the layout discovers its guess is incorrect and/or sees an unexpected viewport shift, it needs to reorient its starting position. The virtualizing layouts that ship as part of the XAML controls are developed as content-dependent layouts as they place fewer restrictions on the nature of the content that will be shown.

Example: Simple Virtualizing Stack Layout for Variable-Sized Items

The sample below demonstrates a simple stack layout for variable-sized items that:

- supports UI virtualization,
- uses estimations to guess the size of unrealized items,
- is aware of potential discontinuous viewport shifts, and
- applies layout corrections to account for those shifts.

Usage: Markup

XAML

```
<ScrollViewer>

  <ItemsRepeater x:Name="repeater" >
    <ItemsRepeater.Layout>

      <local:VirtualizingStackLayout />

    </ItemsRepeater.Layout>
    <ItemsRepeater.ItemTemplate>
      <DataTemplate x:Key="item">
        <UserControl IsTabStop="True" UseSystemFocusVisuals="True"
Margin="5">
          <StackPanel BorderThickness="1" Background="LightGray" Margin="5">
            <Image x:Name="recipeImage" Source="{Binding ImageUri}"
Width="100" Height="100"/>
              <TextBlock x:Name="recipeDescription"
                         Text="{Binding Description}"
                         TextWrapping="Wrap"
                         Margin="10" />
          </StackPanel>
        </UserControl>
      </DataTemplate>
    </ItemsRepeater.ItemTemplate>
  </ItemsRepeater>

</ScrollViewer>

Code: VirtualizingStackLayout.cs

C#

```
// This is a sample layout that stacks elements one after
// the other where each item can be of variable height. This is
// also a virtualizing layout - we measure and arrange only elements
// that are in the viewport. Not measuring/arranging all elements means
// that we do not have the complete picture and need to estimate sometimes.
// For example the size of the layout (extent) is an estimation based on the
// average heights we have seen so far. Also, if you drag the mouse thumb
// and yank it quickly, then we estimate what goes in the new viewport.

// The layout caches the bounds of everything that are in the current
viewport.
// During measure, we might get a suggested anchor (or start index), we use
that
// index to start and layout the rest of the items in the viewport relative
to that
// index. Note that since we are estimating, we can end up with negative
origin when
// the viewport is somewhere in the middle of the extent. This is achieved
by setting the
// LayoutOrigin property on the context. Once this is set, future viewport
will account
// for the origin.

Transforms overview

Article • 11/26/2024

Learn how to use transforms in the Windows Runtime API, by changing the relative coordinate systems of elements in the UI. This can be used to adjust the appearance of individual XAML elements, such as scaling, rotating, or transforming the position in x-y space.

What is a transform?

A *transform* defines how to map, or transform, points from one coordinate space to another coordinate space. When a transform is applied to a UI element, it changes how that UI element is rendered to the screen as part of the UI.

Think of transforms in four broad classifications: translation, rotation, scaling and skew (or shear). For the purposes of using graphics APIs to change the appearance of UI elements, it's usually easiest to create transforms that define only one operation at a time. So the Windows Runtime defines a discrete class for each of these transform classifications:

- **TranslateTransform**: translates an element in x-y space, by setting values for **X** and **Y**.
- **ScaleTransform**: scales the transform based on a center point, by setting values for **CenterX**, **CenterY**, **ScaleX** and **ScaleY**.
- **RotateTransform**: rotates in x-y space, by setting values for **Angle**, **CenterX** and **CenterY**.
- **SkewTransform**: skews or shears in x-y space, by setting values for **AngleX**, **AngleY**, **CenterX** and **CenterY**.

Of these, you're likely to use **TranslateTransform** and **ScaleTransform** most often for UI scenarios.

You can combine transforms, and there are two Windows Runtime classes that support this: **CompositeTransform** and **TransformGroup**. In a **CompositeTransform**, transforms are applied in this order: scale, skew, rotate, translate. Use **TransformGroup** instead of **CompositeTransform** if you want the transforms applied in a different order. For more info, see **CompositeTransform**.

Transforms and layout

In XAML layout, transforms are applied after the layout pass is complete, so available space calculations and other layout decisions have been made before the transforms are applied. Because layout comes first, you'll sometimes get unexpected results if you transform elements that are in a **Grid** cell or similar layout container that allocates space during layout. The transformed element may appear truncated or obscured because it's trying to draw into an area that didn't calculate the post-transform dimensions when dividing space within its parent container. You may need to experiment with the transform results and adjust some settings. For example, instead of relying on adaptive layout and star sizing, you may need to change the **Center** properties or declare fixed pixel measurements for layout space to make sure the parent allots enough space.

Migration note: Windows Presentation Foundation (WPF) had a **LayoutTransform** property that applied transforms prior to the layout pass. But Windows Runtime XAML doesn't support a **LayoutTransform** property. (Microsoft Silverlight didn't have this property either.)

As an alternative, the Windows Community Toolkit provides the LayoutTransformControl that applies Matrix transformations on any FrameworkElement of your application.

Applying a transform to a UI element

When you apply a transform to an object, you typically do so to set the property **UIElement.RenderTransform**. Setting this property does not literally change the object pixel by pixel. What the property really does is apply the transform within the local coordinate space in which that object exists. Then the rendering logic and operation (post-layout) renders the combined coordinate spaces, making it look like the object has changed appearance and also potentially its layout position (if **TranslateTransform** was applied).

By default, each render transform is centered at the origin of the target object's local coordinate system—its (0,0). The only exception is a **TranslateTransform**, which has no center properties to set because the translation effect is the same regardless of where it is centered. But the other transforms each have properties that set **CenterX** and **CenterY** values.

Whenever you use transforms with **UIElement.RenderTransform**, remember that there's another property on **UIElement** that affects how the transform behaves: **RenderTransformOrigin**. What **RenderTransformOrigin** declares is whether the whole transform should apply to the default (0,0) point of an element or to some other origin point within the relative coordinate space of that element. For typical elements, (0,0) places the transform to the top left corner. Depending on what effect you want, you might choose to change **RenderTransformOrigin** rather than adjusting the **CenterX** and

CenterY values on transforms. Note that if you apply both **RenderTransformOrigin** and **CenterX** / **CenterY** values, the results can be pretty confusing, especially if you're animating any of the values.

For hit-testing purposes, an object to which a transform is applied continues to respond to input in an expected way that's consistent to its visual appearance in x-y space. For example, if you've used a **TranslateTransform** to move a **Rectangle** 400 pixels laterally in the UI, that **Rectangle** responds to **PointerPressed** events when the user presses the point where the **Rectangle** appears visually. You won't get false events if the user presses the area where the **Rectangle** was before being translated. For any z-index considerations that affect hit testing, applying a transform makes no difference; the z-index that governs which element handles input events for a point in x-y space is still evaluated using the child order as declared in a container. That order is usually the same as the order in which you declare the elements in XAML, although for child elements of a **Canvas** object you can adjust the order by applying the **Canvas.ZIndex** attached property to child elements.

Other transform properties

- **Brush.Transform**, **Brush.RelativeTransform**: These influence how a **Brush** uses coordinate space within the area that the **Brush** is applied to set visual properties such as foregrounds and backgrounds. These transforms aren't relevant for the most common brushes (which are typically setting solid colors with **SolidColorBrush**) but might be occasionally useful when painting areas with an **ImageBrush** or **LinearGradientBrush**.
- **Geometry.Transform**: You might use this property to apply a transform to a geometry prior to using that geometry for a **Path.Data** property value.

Animating a transform

Transform objects can be animated. To animate a **Transform**, apply an animation of a compatible type to the property you want to animate. This typically means you're using **DoubleAnimation** or **DoubleAnimationUsingKeyFrames** objects to define the animation, because all of the transform properties are of type **Double**. Animations that affect a transform that's used for a **UIElement.RenderTransform** value are not considered to be dependent animations, even if they have a nonzero duration. For more info about dependent animations, see Storyboarded animations.

If you animate properties to produce an effect similar to a transform in terms of the net visual appearance—for example, animating the **Width** and **Height** of a **FrameworkElement** rather than applying a **TranslateTransform**—such animations are

almost always treated as dependent animations. You'd have to enable the animations and there could be significant performance issues with the animation, especially if you're trying to support user interaction while that object is being animated. For that reason it's preferable to use a transform and animate it rather than animating any other property where the animation would be treated as a dependent animation.

To target the transform, there must be an existing **Transform** as the value for **RenderTransform**. You typically put an element for the appropriate transform type in the initial XAML, sometimes with no properties set on that transform.

You typically use an indirect targeting technique to apply animations to the properties of a transform. For more info about indirect targeting syntax, see Storyboarded animations and Property-path syntax.

Default styles for controls sometimes define animations of transforms as part of their visual-state behavior. For example, the visual states for **ProgressRing** use animated **RotateTransform** values to "spin" the dots in the ring.

Here's a simple example of how to animate a transform. In this case, it's animating the **Angle** of a **RotateTransform** to spin a **Rectangle** in place around its visual center. This example names the **RotateTransform** so doesn't need indirect animation targeting, but you could alternatively leave the transform unnamed, name the element that the transform's applied to, and use indirect targeting such as `(UIElement.RenderTransform).(RotateTransform.Angle)`.

XML

```
<StackPanel Margin="15">
  <StackPanel.Resources>
    <Storyboard x:Name="myStoryboard">
      <DoubleAnimation
       Storyboard.TargetName="myTransform"
       Storyboard.TargetProperty="Angle"
       From="0" To="360" Duration="0:0:5"
       RepeatBehavior="Forever" />
    </Storyboard>
  </StackPanel.Resources>
  <Rectangle Width="50" Height="50" Fill="RoyalBlue"
   PointerPressed="StartAnimation">
    <Rectangle.RenderTransform>
      <RotateTransform x:Name="myTransform" Angle="45" CenterX="25"
CenterY="25" />
    </Rectangle.RenderTransform>
  </Rectangle>
</StackPanel>
```

XML

```
void StartAnimation (object sender, RoutedEventArgs e) {
    myStoryboard.Begin();
}
```

Accounting for coordinate frames of reference at run time

UIElement has a method named TransformToVisual, which can generate a Transform that correlates the coordinate frames of reference for two UI elements. You can use this to compare an element to the app's default coordinate frame of reference if you pass the root visual as the first parameter. This can be useful if you've captured an input event from a different element, or if you are trying to predict layout behavior without actually requesting a layout pass.

Event data obtained from pointer events provides access to a GetCurrentPoint method, where you can specify a *relativeTo* parameter to change the coordinate frame of reference to a specific element rather than the app default. This approach simply applies a translate transform internally and transforms the x-y coordinate data for you when it creates the returned PointerPoint object.

Describing a transform mathematically

A transform can be described in terms of a transformation matrix. A 3×3 matrix is used to describe the transformations in a two-dimensional, x-y plane. Affine transformation matrices can be multiplied to form any number of linear transformations, such as rotation and skew (shear), followed by translation. The final column of an affine transformation matrix is equal to (0, 0, 1), so you need to specify only the members of the first two columns in the mathematical description.

The mathematical description of a transform might be useful to you if you have a mathematical background or a familiarity with graphics-programming techniques that also use matrices to describe transformations of coordinate space. There's a Transform-derived class that enables you to express a transformation directly in terms of its 3×3 matrix: MatrixTransform. **MatrixTransform** has a Matrix property, which holds a structure that has six properties: M11, M12, M21, M22, OffsetX and OffsetY. Each Matrix property uses a **Double** value and corresponds to the six relevant values (columns 1 and 2) of an affine transformation matrix.

Expand table

Column 1	Column 2	Column 3
M11	M12	0
M21	M22	0
OffsetX	OffsetY	1

Any transform that you could describe with a **TranslateTransform**, **ScaleTransform**, **RotateTransform**, or **SkewTransform** object could be described equally by a **MatrixTransform** with a **Matrix** value. But you typically just use **TranslateTransform** and the others because the properties on those transform classes are easier to conceptualize than setting the vector components in a **Matrix**. It's also easier to animate the discrete properties of transforms; a **Matrix** is actually a structure and not a **DependencyObject**, so it can't support animated individual values.

Some XAML design tools that enable you to apply transformation operations will serialize the results as a **MatrixTransform**. In this case it may be best to use the same design tool again to change the transformation effect and serialize the XAML again, rather than trying to manipulate the **Matrix** values yourself directly in the XAML.

3-D transforms

In Windows 10, XAML introduced a new property, **UIElement.Transform3D**, that can be used to create 3D effects with UI. To do this, use **PerspectiveTransform3D** to add a shared 3D perspective or "camera" to your scene, and then use **CompositeTransform3D** to transform an element in 3D space, like you would use **CompositeTransform**. See **UIElement.Transform3D** for a discussion of how to implement 3D transforms.

For simpler 3D effects that only apply to a single object, the **UIElement.Projection** property can be used. Using a **PlaneProjection** as the value for this property is equivalent to applying a fixed perspective transform and one or more 3D transforms to the element. This type of transform is described in more detail in 3-D perspective effects for XAML UI.

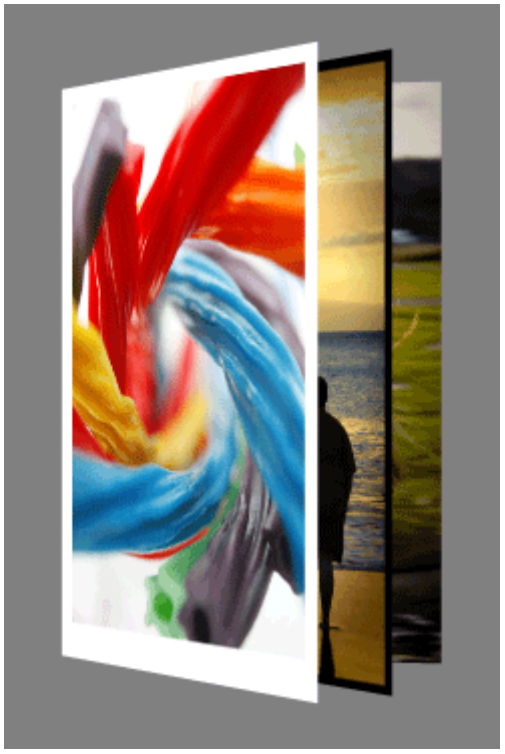
3-D perspective effects for XAML UI

Article • 11/26/2024

You can apply 3-D effects to content in your Windows Runtime apps using perspective transforms. For example, you can create the illusion that an object is rotated toward or away from you, as shown here.

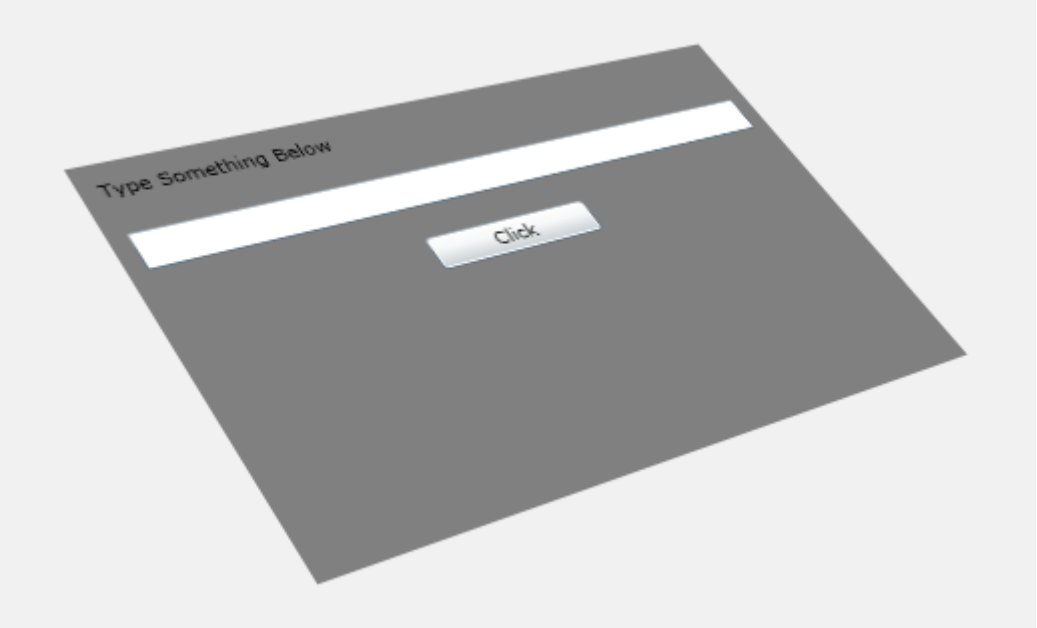
Another common usage for perspective transforms is to arrange objects in relation to one another to create a 3-D effect, as here.



Besides creating static 3-D effects, you can animate the perspective transform properties to create moving 3-D effects.

You just saw perspective transforms applied to images, but you can apply these effects to any **UIElement**, including controls. For example, you can apply a 3-D effect to an

entire container of controls like this:



Here is the XAML code used to create this sample:

XML

```
<StackPanel Margin="35" Background="Gray">
    <StackPanel.Projection>
        <PlaneProjection RotationX="-35" RotationY="-35" RotationZ="15"  />
    </StackPanel.Projection>
    <TextBlock Margin="10">Type Something Below</TextBlock>
    <TextBox Margin="10"></TextBox>
    <Button Margin="10" Content="Click" Width="100" />
</StackPanel>
```

Here we focus on the properties of **PlaneProjection** which is used to rotate and move objects in 3-D space. The next sample allows you to experiment with these properties and see their effect on an object.

PlaneProjection class

You can apply 3D effects can to any **UIElement**, by setting the UIElement's **Projection** property using a **PlaneProjection**. The **PlaneProjection** defines how the transform is rendered in space. The next example shows a simple case.

XML

```
<Image Source="kid.png">
    <Image.Projection>
        <PlaneProjection RotationX="-35"   />
```

```
    </Image.Projection>
</Image>
```

This figure shows what the image renders as. The x-axis, y-axis, and z-axis are shown as red lines. The image is rotated backward 35 degrees around the x-axis using the **RotationX** property.

The **RotationY** property rotates around the y-axis of the center of rotation.

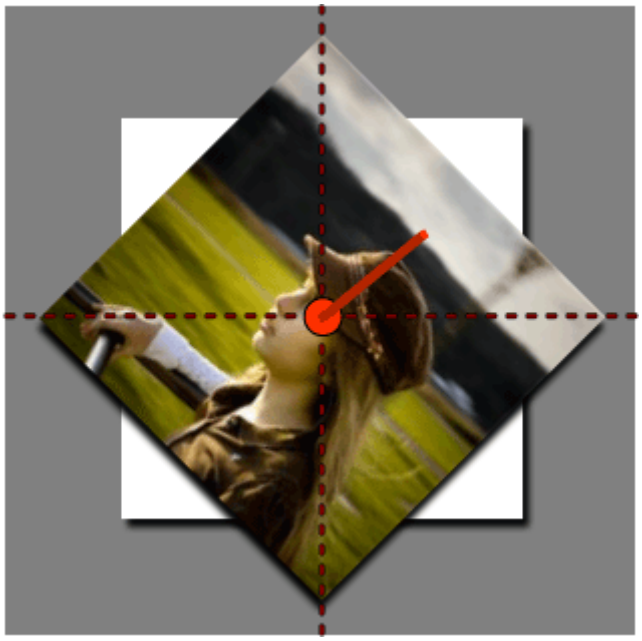
XML

```
<Image Source="kid.png">
    <Image.Projection>
        <PlaneProjection RotationY="-35"    />
    </Image.Projection>
</Image>
```

The **RotationZ** property rotates around the z-axis of the center of rotation (a line that is perpendicular to the plane of the object).

XML

```
<Image Source="kid.png">
    <Image.Projection>
        <PlaneProjection RotationZ="-45"/>
    </Image.Projection>
</Image>
```



The rotation properties can specify a positive or negative value to rotate in either direction. The absolute number can be greater than 360, which rotates the object more than one full rotation.

You can move the center of rotation by using the CenterOfRotationX, CenterOfRotationY, and CenterOfRotationZ properties. By default, the axes of rotation run directly through the center of the object, causing the object to rotate around its center. But if you move the center of rotation to the outer edge of the object, it will rotate around that edge. The default values for **CenterOfRotationX** and **CenterOfRotationY** are 0.5, and the default value for **CenterOfRotationZ** is 0. For **CenterOfRotationX** and **CenterOfRotationY**, values between 0 and 1 set the pivot point at some location within the object. A value of 0 denotes one object edge and 1 denotes the opposite edge. Values outside of this range are allowed and will move the center of rotation accordingly. Because the z-axis of the center of rotation is drawn through the plane of the object, you can move the center of rotation behind the object using a negative number and in front of the object (toward you) using a positive number.

CenterOfRotationX moves the center of rotation along the x-axis parallel to the object while CenterOfRotationY moves the center or rotation along the y-axis of the object. The next illustrations demonstrate using different values for **CenterOfRotationY**.

XML

```
<Image Source="kid.png">
    <Image.Projection>
        <PlaneProjection RotationX="-35" CenterOfRotationY="0.5" />
    </Image.Projection>
</Image>
```

CenterOfRotationY = "0.5" (default)

XML

```
<Image Source="kid.png">
    <Image.Projection>
        <PlaneProjection RotationX="-35" CenterOfRotationY="0.1"/>
    </Image.Projection>
</Image>
```

CenterOfRotationY = "0.1"

Notice how the image rotates around the center when the **CenterOfRotationY** property is set to the default value of 0.5 and rotates near the upper edge when set to 0.1. You

see similar behavior when changing the CenterOfRotationX property to move where the RotationY property rotates the object.

XML

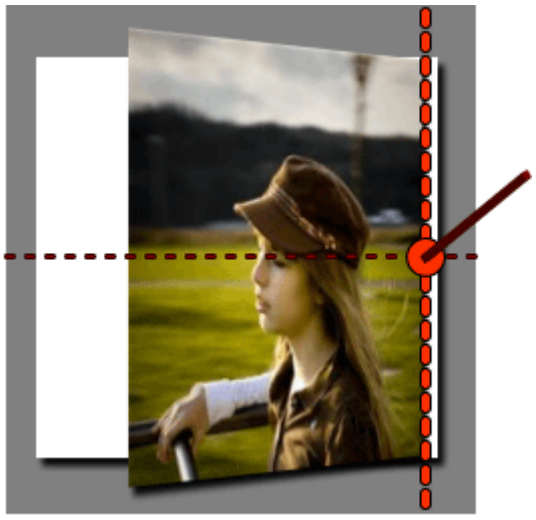
```
<Image Source="kid.png">
    <Image.Projection>
        <PlaneProjection RotationY="-35" CenterOfRotationX="0.5" />
    </Image.Projection>
</Image>
```

CenterOfRotationX = "0.5" (default)

XML

```
<Image Source="kid.png">
    <Image.Projection>
        <PlaneProjection RotationY="-35" CenterOfRotationX="0.5" />
    </Image.Projection>
</Image>
```

CenterOfRotationX = "0.9" (right-hand edge)



Use the CenterOfRotationZ to place the center of rotation above or below the plane of the object. This way, you can rotate the object around the point analogous to a planet orbiting around a star.

Positioning an object

So far, you learned how to rotate an object in space. You can position these rotated objects in space relative to one another by using these properties:

- LocalOffsetX moves an object along the x-axis of the plane of a rotated object.
- LocalOffsetY moves an object along the y-axis of the plane of a rotated object.
- LocalOffsetZ moves an object along the z-axis of the plane of a rotated object.
- GlobalOffsetX moves an object along the screen-aligned x-axis.
- GlobalOffsetY moves an object along the screen-aligned y-axis.
- GlobalOffsetZ moves an object along the screen-aligned z-axis.

Local offset

The LocalOffsetX, LocalOffsetY, and LocalOffsetZ properties translate an object along the respective axis of the plane of the object after it has been rotated. Therefore, the rotation of the object determines the direction that the object is translated. To demonstrate this concept, the next sample animates **LocalOffsetX** from 0 to 400 and RotationY from 0 to 65 degrees.

Notice in the preceding sample that the object is moving along its own x-axis. At the very beginning of the animation, when the RotationY value is near zero (parallel to the screen), the object moves along the screen in the x direction, but as the object rotates toward you, the object moves along the x-axis of the plane of the object toward you. On the other hand, if you animated the **RotationY** property to -65 degrees, the object would curve away from you.

LocalOffsetY works similarly to LocalOffsetX, except that it moves along the vertical axis, so changing RotationX affects the direction **LocalOffsetY** moves the object. In the next sample, **LocalOffsetY** is animated from 0 to 400 and **RotationX** from 0 to 65 degrees.

LocalOffsetZ translates the object perpendicular to the plane of the object as though a vector was drawn directly through the center from behind the object out toward you. To demonstrate how **LocalOffsetZ** works, the next sample animates **LocalOffsetZ** from 0 to 400 and RotationX from 0 to 65 degrees.

At the beginning of the animation, when the RotationX value is near zero (parallel to the screen), the object moves directly out toward you, but as the face of the object rotates down, the object moves down instead.

Global offset

The GlobalOffsetX, GlobalOffsetY, and GlobalOffsetZ properties translate the object along axes relative to the screen. That is, unlike the local offset properties, the axis the object moves along is independent of any rotation applied to the object. These properties are useful when you want to simply move the object along the x-, y-, or z-axis of the screen without worrying about the rotation applied to the object.

The next sample animates GlobalOffsetX from 0 to 400 and RotationY from 0 to 65 degrees.

Notice in this sample that the object does not change course as it rotates. That is because the object is being moved along the x-axis of the screen without regard to its rotation.

More complex semi-3D scenarios

You can use the Matrix3DProjection and Matrix3D types for more complex semi-3D scenarios than are possible with the PlaneProjection. **Matrix3DProjection** provides you with a complete 3D transform matrix to apply to any UIElement, so that you can apply arbitrary model transformation matrices and perspective matrices to elements. Keep in mind that these API are minimal and therefore if you use them, you will need to write the code that correctly creates the 3D transform matrices. Because of this, it is easier to use **PlaneProjection** for simple 3D scenarios.

Manage app windows (Windows App SDK)

Article • 07/09/2024

This topic contains a Code example section.

The Windows App SDK provides the easy-to-use **Microsoft.UI.Windowing.AppWindow** class. **AppWindow** is framework-agnostic, and available to all Windows apps including Win32, WPF, and WinForms. You can contrast the framework-agnostic nature of **AppWindow** to **Microsoft.UI.Xaml.Window**, which is the window class specifically for the WinUI 3 framework. **AppWindow** is also an evolution of the Universal Windows Platform's (UWP's) **Windows.UI.WindowManagement.AppWindow**.

The Windows App SDK version of **Microsoft.UI.Windowing.AppWindow** doesn't rely on asynchronous patterns; and it provides immediate feedback to your app about whether API calls have succeeded.

Also Get started with WinUI and Use the Windows App SDK in an existing project.

The AppWindow class

Microsoft.UI.Windowing.AppWindow is a high-level windowing API that allows for easy-to-use windowing scenarios. **AppWindow** integrates well with the Windows UI/UX, and with other apps.

AppWindow represents a high-level abstraction of a system-managed container for the content of an app. It's the container in which your content is hosted; and it represents the entity that users interact with when they resize and move your app on-screen. If you're familiar with Win32, the *app window* can be seen as a high-level abstraction of the **HWND**. If you're familiar with UWP, then the *app window* can be seen as a replacement for **CoreWindow**/**ApplicationView**/**Windows.UI.WindowManagement.AppWindow**.

For the Windows App SDK version of **Microsoft.UI.Windowing.AppWindow** we're supporting only top-level **HWND**s. There's a 1:1 mapping between an **AppWindow** and a top-level **HWND**.

The lifetime of an **AppWindow** object and an **HWND** is the same—the **AppWindow** is available immediately after the window has been created; and it's destroyed when the window is closed.

The AppWindowPresenter class, and subclasses

Each **AppWindow** has an **AppWindowPresenter** (presenter) applied to it. If you're a UWP developer who's worked with **Windows.UI.WindowManagement.AppWindow**, then this will be familiar; even if it's not a 1:1 mapping of functionality and behavior. Also see See Windowing functionality migration.

As a new concept to the Win32 application model, a presenter is akin to (but not the same as) a combination of window state and styles. Some presenters also have UI/UX behaviors defined in them that aren't inspectable from classic window state and style properties (such as an auto-hiding titlebar).

By default, a presenter is created by the system, and applied to an **AppWindow** at creation time. In the Windows App SDK 1.0, on Windows desktop, the type of presenter is **OverlappedPresenter**, which is a subclass of **AppWindowPresenter**. There's no need for your app to stash it, nor to keep a reference to it in order to go back to the default presenter for a window after having applied another presenter. That's because the system keeps the same instance of this presenter around for the lifetime of the **AppWindow** for which it was created; and your app can reapply it by calling the **AppWindow.SetPresenter** method with **AppWindowPresenterKind.Default** as a parameter.

A presenter can be applied to only a single window at a time. Trying to apply the same presenter to a second window throws an exception. That means that if you have multiple windows, and you want to switch each one into a specific presentation mode, then you need to create multiple presenters of the same kind, and then apply each to its own window.

Some presenters have functionality that allows a user to make changes outside of your app's own control. When such a change happens, your app is notified by an **AppWindow.Changed** event on the affected **AppWindow**, with the **AppWindowChangedEventArgs.DidPresenterChange** property set to `true`. Your app should then inspect the property of the applied presenter to see what changed.

The applied presenter is a live object. A change to any property of the **AppWindow.Presenter** object takes effect immediately.

A presenter can't be destroyed while it's applied to a window. To destroy a presenter object, first apply a different presenter object to the window; that way, the presenter that you intend to destroy is removed from the window. You can do that either by applying another specific presenter to the window, or by calling the **AppWindow.SetPresenter** method with **AppWindowPresenterKind.Default** as an argument, which will reapply the default system-created presenter to the window. If you

happened to keep a reference to the system-created presenter for the window, then it will be valid at this point (that is, the instance that was first created for the window is re-applied).

Available presenters

These **AppWindowPresenter**-derived presenters are provided, and they're available on all of the supported OS versions.

- **CompactOverlayPresenter**. Creates an *always-on-top* window of a fixed size, with a 16:9 aspect ratio to allow for *picture-in-picture*-like experiences.
- **FullScreenPresenter**. Allows a window to go into a full-screen experience.
- **OverlappedPresenter**. The system-created default presenter, which allows you to request and react to minimize/maximize/restore operations and state changes.

UI framework and HWND interop

The **AppWindow** class is available for *any* top-level **HWND** in your app. That means that when you're working with a desktop UI framework (including WinUI 3), you can continue to use that framework's entry point for creating a window, and attaching its content. And once you've created a window with that UI framework, you can use the windowing interop functions (see below) provided in the Windows App SDK to access the corresponding **AppWindow** and its methods, properties, and events.

Some of the benefits of using **AppWindow** (even when working with a UI framework) are:

- Easy title bar customization; which by default maintains the Windows 11 UI (rounded corners, snap group flyout).
- System-provided full-screen and compact overlay (picture-in-picture) experiences.
- Windows Runtime (WinRT) API surface for some of the core Win32 windowing concepts.

Code example

This code example demonstrates how to retrieve a **Microsoft.UI.Windowing.AppWindow** from a WinUI 3 window by using the **Microsoft.UI.Xaml.Window.AppWindow** property. To use the example, create a new **Blank App, Packaged (WinUI 3 in Desktop)** project, and paste the code in.

For additional details on how to work with **AppWindow**, see the Windowing gallery sample.

C#

```
// MainWindow.xaml.cs
private void myButton_Click(object sender, RoutedEventArgs e)
{
    // Retrieve the AppWindow for the current (XAML) WinUI 3 window.
    Microsoft.UI.Windowing.AppWindow appWindow = this.AppWindow;

    if (appWindow != null)
    {
        // With a non-null AppWindow object, you can call its methods
        // to manipulate the window. As an example, let's change the title
        // text of the window.
        appWindow.Title = "Title text updated via AppWindow!";
    }
}
```

Code example for versions of Windows App SDK prior to 1.3 (or other desktop app frameworks)

The **Microsoft.UI.Xaml.Window.AppWindow** property (used in the code example above) is available in Windows App SDK version 1.3 and later. For earlier versions, you can use the functionally equivalent code example in this section.

C#. .NET wrappers for the windowing interop functions are implemented as methods of the **Microsoft.UI.Win32Interop** class. Also see Call interop APIs from a .NET app.

C++. The interop functions are defined in the winrt/Microsoft.ui.interop.h header file.

The Code example section below shows actual source code; but here's the recipe for retrieving an **AppWindow** object given an existing window:

1. Retrieve the **HWND** for your existing window object (for your UI framework), if you don't already have it.
2. Pass that **HWND** to the **GetWindowIdFromWindow** interop function to retrieve a **WindowId**.
3. Pass that **WindowId** to the static **AppWindow.GetFromWindowId** method to retrieve the **AppWindow**.

C#

```
// MainWindow.xaml.cs
private void myButton_Click(object sender, RoutedEventArgs e)
{
    // Retrieve the window handle (HWND) of the current (XAML) WinUI 3
window.
    var hWnd =
        WinRT.Interop.WindowNative.GetWindowHandle(this);

    // Retrieve the WindowId that corresponds to hWnd.
    Microsoft.UI.WindowId windowId =
        Microsoft.UI.Win32Interop.GetWindowIdFromWindow(hWnd);

    // Lastly, retrieve the AppWindow for the current (XAML) WinUI 3 window.
    Microsoft.UI.Windowing.AppWindow appWindow =
        Microsoft.UI.Windowing.AppWindow.GetFromWindowId(windowId);

    if (appWindow != null)
    {
        // You now have an AppWindow object, and you can call its methods to
manipulate the window.
        // As an example, let's change the title text of the window.
        appWindow.Title = "Title text updated via AppWindow!";
    }
}
```

Limitations

- **AppWindow** is a WinUI 3 API. That means that it's available only to desktop apps (both packaged and unpackaged); and isn't available to UWP apps.
- The Windows App SDK doesn't currently provide methods for attaching UI framework content to an **AppWindow**. But see the Code example section.
- Title bar customization is supported in Windows 11 and later; and in Windows 10 for version 1.2 and later of the Windows App SDK. For details, see Title bar customization.

Retrieve a window handle (HWND)

Article • 08/28/2024

This topic shows you how, in a desktop app, to retrieve the window handle for a window. The scope covers WinUI 3, Windows Presentation Foundation (WPF), and Windows Forms (WinForms) apps; code examples are presented in C# and C++/WinRT.

The development and UI frameworks listed above are (behind the scenes) built on the Win32 API. In Win32, a window object is identified by a value known as a window handle. And the type of a window handle is an **HWND** (although it surfaces in C# as an **IntPtr**). In any case, you'll hear the term **HWND** used as a shorthand for *window handle*.

There are several reasons to retrieve the **HWND** for a window in your WinUI 3, WPF, or WinForms desktop app. One example is to use the **HWND** to interoperate with certain Windows Runtime (WinRT) objects that depend on a **CoreWindow** to display a user-interface (UI). For more info, see Display WinRT UI objects that depend on CoreWindow.

WinUI 3 with C#

The C# code below shows how to retrieve the window handle (HWND) for a WinUI 3 Window object. This example calls the **GetWindowHandle** method on the **WinRT.Interop.WindowNative** C# interop class. For more info about the C# interop classes, see Call interop APIs from a .NET app.

C#

```
// MainWindow.xaml.cs
private async void myButton_Click(object sender, RoutedEventArgs e)
{
    // Retrieve the window handle (HWND) of the current WinUI 3 window.
    var hWnd = WinRT.Interop.WindowNative.GetWindowHandle(this);
}
```

WinUI 3 with C++

The C++/WinRT code below shows how to retrieve the window handle (HWND) for a WinUI 3 Window object. This example calls the **IWindowNative::get_WindowHandle** method.

C++/WinRT

```
// pch.h
...
#include <microsoft.ui.xaml.window.h>

// MainWindow.xaml.cpp
void MainWindow::myButton_Click(IInspectable const&, RoutedEventArgs const&)
{
    // Retrieve the window handle (HWND) of the current WinUI 3 window.
    auto windowNative{ this->m_inner.as<::IWindowNative>() };
    HWND hWnd{ 0 };
    windowNative->get_WindowHandle(&hWnd);
}
```

WPF with C#

The C# code below shows how to retrieve the window handle (HWND) for a WPF window object. This example uses the **WindowInteropHelper** class.

C#

```
// MainWindow.xaml.cs
private void Button_Click(object sender, RoutedEventArgs e)
{
    var wih = new System.Windows.Interop.WindowInteropHelper(this);
    var hWnd = wih.Handle;
}
```

WinForms with C#

The C# code below shows how to retrieve the window handle (HWND) for a WinForms form object. This example uses the **NativeWindow.Handle** property.

C#

```
// Form1.cs
private void button1_Click(object sender, EventArgs e)
{
    var hWnd = this.Handle;
}
```

Determining the window that's hosting a visual element

From a visual element, you can access UIElement.XamlRoot; then XamlRoot.ContentIslandEnvironment; then the ContentIslandEnvironment.AppWindowId property contains the ID of the top-level Win32 HWND.

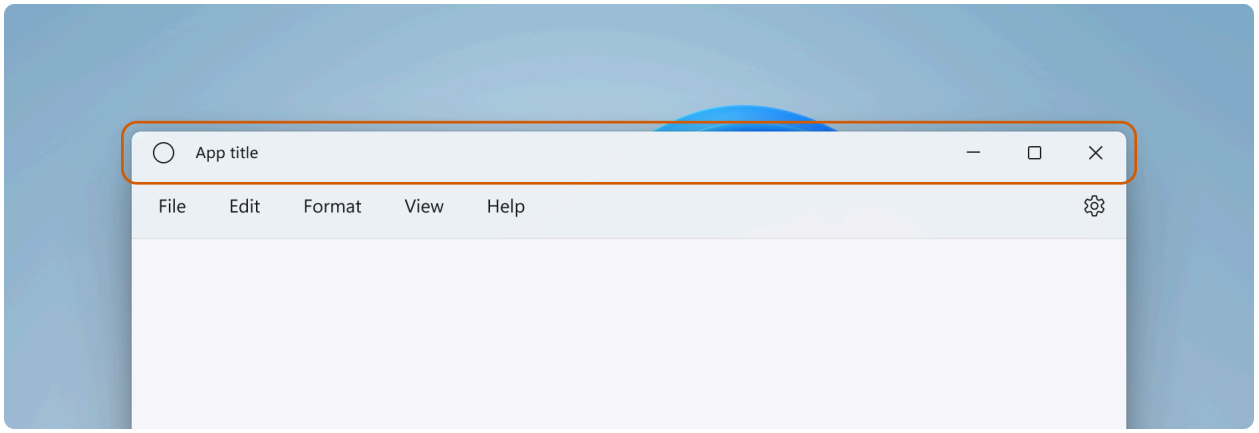
Title bar customization

Article • 11/21/2024

Windows provides a default title bar for every window and lets you customize it to match the personality of your app. The default title bar comes with some standard components and core functionality such as dragging and resizing the window.



See the Title bar design article for guidance on customizing your app's title bar, acceptable title bar area content, and recommended UI patterns.

See the Windows 11 Fluent Design guidance for title bar

> **Important**
>
> This article shows how to customize the title bar for apps that use the Windows App SDK, either with or without WinUI 3. For apps that use UWP and WinUI 2, see Title bar customization for UWP.

- **Applies to**: Windows App SDK, WinUI 3 desktop apps
- **Important APIs**: AppWindow.TitleBar property, AppWindowTitleBar class, AppWindow class, Microsoft.UI.Xaml.Window class, Window.ExtendsContentIntoTitleBar property, Window.SetTitleBar method

Title bar components

This list describes the components of the standard title bar.

- Title bar rectangle
- Title text
- System icon
- System menu - accessed by clicking the app icon or right-clicking the title bar

- Caption controls
  - Minimize button
  - Maximize/Restore button
  - Close button

Windowing

Windowing functionality in the Windows App SDK is through the Microsoft.UI.Windowing.AppWindow class, which is based on the Win32 HWND model. There's a 1:1 mapping between an AppWindow and a top-level HWND in your app. AppWindow and its related classes provide APIs that let you manage many aspects of your app's top-level windows, including customization of the title bar. You can modify the default title bar that Windows provides so that it blends with the rest of your UI, or extend your app canvas into the title bar area and provide your own title bar content.

Windowing functionality in WinUI 3 is through the Microsoft.UI.Xaml.Window class, which is also based on the Win32 HWND model. For XAML apps that use WinUI 3, XAML Window APIs provide a simpler way to customize the title bar, while still letting you access the AppWindow APIs when needed.

How to work with AppWindow

You can use AppWindow APIs with any UI framework that the Windows App SDK supports - Win32, WPF, WinForms, or WinUI 3 - and you can adopt them incrementally, using only the APIs you need.

If you use WinUI 3 XAML as your app's UI framework, both the Window and the AppWindow APIs are available to you. Starting in Windows App SDK 1.4, the XAML Window and AppWindow use the same AppWindowTitleBar object for title bar customization. Use the Window.AppWindow property to get an AppWindow object from an existing XAML window. With this AppWindow object you have access to the title bar customization APIs. To access additional features of the title bar, you can use the AppWindow APIs from your XAML Window like this: `AppWindow.TitleBar.ForegroundColor = Colors.White;`.

If you're not using WinUI 3 1.3 or later, use interop APIs to get the AppWindow and use the AppWindow APIs to customize the title bar. For more about the interop APIs, see Manage app windows - UI framework and HWND interop and the Windowing gallery sample.

How much to customize the title bar

There are two levels of customization that you can apply to the title bar: apply minor modifications to the default title bar, or extend your app canvas into the title bar area and provide completely custom content.

Simple

For simple customization, such as changing the title bar color, you can set properties on the AppWindowTitleBar object to specify the colors you want to use for title bar elements. In this case, the system retains responsibility for all other aspects of the title bar, such as drawing the app title and defining drag areas.

Full

Your other option is to hide the default system title bar and replace it with your own custom content. For example, you can place text, a search box, or custom menus in the title bar area. You will also need to use this option to extend a material backdrop, like Mica, into the title bar area.

When you opt for full customization, you are responsible for putting content in the title bar area, and you can define your own drag regions. The caption controls (system Close, Minimize, and Maximize buttons) are still available and handled by the system, but elements like the app title are not. You will need to create those elements yourself as needed by your app.

Simple customization

If you want only to customize the title bar title, colors, or icon, you can set properties on the title bar object for your app window.

Title

By default, the title bar shows the app type as the window title (for example, "WinUI Desktop"). You should update the window title to show a meaningful display name for your app.

A XAML app has a display name that's set in the `Package.appxmanifest` file. You can get this value and use it to set the `Title` property like this.

```
C#
```

```
Title = AppInfo.Current.DisplayInfo.DisplayName;
```

To change the window title, set the Window.Title property to a single-line text value, as shown here.

XAML

```
<Window
    ...
    Title="App title">
    ...
</Window>
```

C#

```
public MainWindow()
{
    InitializeComponent();
    Title = "App title";
}
```

To change the window title using AppWindow APIs, set the AppWindow.Title property to a single-line text value, as shown here. This example shows how to use interop APIs to get the AppWindow, which is needed of your app does not use WinUI 3 1.3 or later.

C#

```
using Microsoft.UI;           // Needed for WindowId.
using Microsoft.UI.Windowing; // Needed for AppWindow.
using WinRT.Interop;          // Needed for XAML/HWND interop.

private AppWindow m_AppWindow;

public MainWindow()
{
    this.InitializeComponent();

    m_AppWindow = GetAppWindowForCurrentWindow();
    m_AppWindow.Title = "App title";
}

private AppWindow GetAppWindowForCurrentWindow()
{
    IntPtr hWnd = WindowNative.GetWindowHandle(this);
    WindowId wndId = Win32Interop.GetWindowIdFromWindow(hWnd);
    return AppWindow.GetFromWindowId(wndId);
}
```

Colors

To customize the default title bar colors or to change the default window icon, you will need to use the AppWindow APIs or opt to fully customize your title bar.

This example shows how to get an instance of AppWindowTitleBar and set its color properties.

> **ⓘ Important**
>
> Color customization is ignored when the app runs on Windows 10.

C#

```
// Assumes "this" is a XAML Window. In projects that don't use
// WinUI 3 1.3 or later, use interop APIs to get the AppWindow.
AppWindow m_AppWindow = this.AppWindow;

private bool SetTitleBarColors()
{
    // Check to see if customization is supported.
    // The method returns true on Windows 10 since Windows App SDK 1.2,
    // and on all versions of Windows App SDK on Windows 11.
    if (AppWindowTitleBar.IsCustomizationSupported())
    {
        AppWindowTitleBar m_TitleBar = m_AppWindow.TitleBar;

        // Set active window colors.
        // Note: No effect when app is running on Windows 10
        // because color customization is not supported.
        m_TitleBar.ForegroundColor = Colors.White;
        m_TitleBar.BackgroundColor = Colors.Green;
        m_TitleBar.ButtonForegroundColor = Colors.White;
        m_TitleBar.ButtonBackgroundColor = Colors.SeaGreen;
        m_TitleBar.ButtonHoverForegroundColor = Colors.Gainsboro;
        m_TitleBar.ButtonHoverBackgroundColor = Colors.DarkSeaGreen;
        m_TitleBar.ButtonPressedForegroundColor = Colors.Gray;
        m_TitleBar.ButtonPressedBackgroundColor = Colors.LightGreen;

        // Set inactive window colors.
        // Note: No effect when app is running on Windows 10
        // because color customization is not supported.
        m_TitleBar.InactiveForegroundColor = Colors.Gainsboro;
        m_TitleBar.InactiveBackgroundColor = Colors.SeaGreen;
        m_TitleBar.ButtonInactiveForegroundColor = Colors.Gainsboro;
        m_TitleBar.ButtonInactiveBackgroundColor = Colors.SeaGreen;
        return true;
    }
```

```
    return false;
}
```

There are a few things to be aware of when setting title bar colors:

- The button background color is not applied to the close button *hover* and *pressed* states. The close button always uses the system-defined color for those states.
- Setting a color property to `null` resets it to the default system color.
- You can't set transparent colors. The color's alpha channel is ignored.

Windows gives a user the option to apply their selected accent color to the title bar. If you set any title bar color, we recommend that you explicitly set all the colors. This ensures that there are no unintended color combinations that occur because of user defined color settings.

Icon and system menu

You can hide the system icon, or replace it with a custom icon. The system icon shows the system menu when right clicked or tapped once. It closes the window when double clicked/tapped.

To show or hide the system icon and associated behaviors, set the title bar IconShowOptions property.

```
C#

m_TitleBar.IconShowOptions = IconShowOptions.HideIconAndSystemMenu;
```

To use a custom window icon, call one of the AppWindow.SetIcon methods to set the new icon.

- `SetIcon(String)`

  The SetIcon(String) method currently works only with .ico files. The string you pass to this method is the fully qualified path to the .ico file.

  ```
  C#

  m_AppWindow.SetIcon("iconPath/iconName.ico");
  ```

- `SetIcon(IconId)`

If you already have a handle to an icon (`HICON`) from one of the Icon functions like CreateIcon, you can use the GetIconIdFromIcon interop API to get an IconId. You can then pass the `IconId` to the SetIcon(IconId) method to set your window icon.

```
C#

m_AppWindow.SetIcon(iconId));
```

Full customization

When you opt-in to full title bar customization, your app's client area is extended to cover the entire window, including the title bar area. You are responsible for drawing and input-handling for the entire window except the caption buttons, which are still provided by the window.

To hide the system title bar and extend your content into the title bar area, set the property that extends app content into the title bar area to `true`. In a XAML app, this property can be set in your app's `OnLaunched` method (*App.xaml.cs*), or in your app's first page.

> **Tip**
>
> See the **Full customization example** section to see all the code at once.

This example shows how to set the Window.ExtendsContentIntoTitleBar property to `true`.

```
C#

public MainWindow()
{
    this.InitializeComponent();

    // Hide system title bar.
    ExtendsContentIntoTitleBar = true;
}
```

> **Caution**
>
> `ExtendsContentIntoTitleBar` shows in the XAML IntelliSense for `Window`, but setting it in XAML causes an error. Set this property in code instead.

This example shows how to get the AppWindowTitleBar and set the AppWindowTitleBar.ExtendsContentIntoTitleBar property to `true`. This example shows how to use interop APIs to get the AppWindow, which is needed if your app does not use WinUI 3 1.3 or later.

C#

```
using Microsoft.UI;           // Needed for WindowId.
using Microsoft.UI.Windowing; // Needed for AppWindow.
using WinRT.Interop;          // Needed for XAML/HWND interop.

private AppWindow m_AppWindow;

public MainWindow()
{
    this.InitializeComponent();

    m_AppWindow = GetAppWindowForCurrentWindow();
    var titleBar = m_AppWindow.TitleBar;
    // Hide system title bar.
    titleBar.ExtendsContentIntoTitleBar = true;
}

private AppWindow GetAppWindowForCurrentWindow()
{
    IntPtr hWnd = WindowNative.GetWindowHandle(this);
    WindowId wndId = Win32Interop.GetWindowIdFromWindow(hWnd);
    return AppWindow.GetFromWindowId(wndId);
}
```

Title bar content and the default drag region

When your app is extended into the title bar area, you're responsible for defining and managing the UI for the title bar. This typically includes, at a minimum, specifying title text and the drag region. The drag region of the title bar defines where the user can click and drag to move the window around. It's also where the user can right-click to show the system menu.

To learn more about acceptable title bar content and recommended UI patterns, see Title bar design.

This example shows the XAML for a custom title bar UI without interactive content.

XAML

```
<Grid x:Name="AppTitleBar"
      Height="32">
```

```
    <Grid.ColumnDefinitions>
        <ColumnDefinition x:Name="LeftPaddingColumn" Width="0"/>
        <ColumnDefinition/>
        <ColumnDefinition x:Name="RightPaddingColumn" Width="0"/>
    </Grid.ColumnDefinitions>
    <Image x:Name="TitleBarIcon" Source="ms-appx:///Assets/StoreLogo.png"
           Grid.Column="1"
           HorizontalAlignment="Left"
           Width="16" Height="16"
           Margin="8,0,0,0"/>
    <TextBlock x:Name="TitleBarTextBlock"
               Text="App title"
               Style="{StaticResource CaptionTextBlockStyle}"
               Grid.Column="1"
               VerticalAlignment="Center"
               Margin="28,0,0,0"/>
</Grid>
```

> **ⓘ Important**
>
> The `LeftPaddingColumn` and `RightPaddingColumn` are used to reserve space for the caption buttons. The `Width` values for these columns are set in code, which is shown later. See the ***System caption buttons*** section for the code and explanation.

A XAML app has a display name that's set in the Package.appxmanifest file. You can get this value and use it in your custom title bar like this.

C#

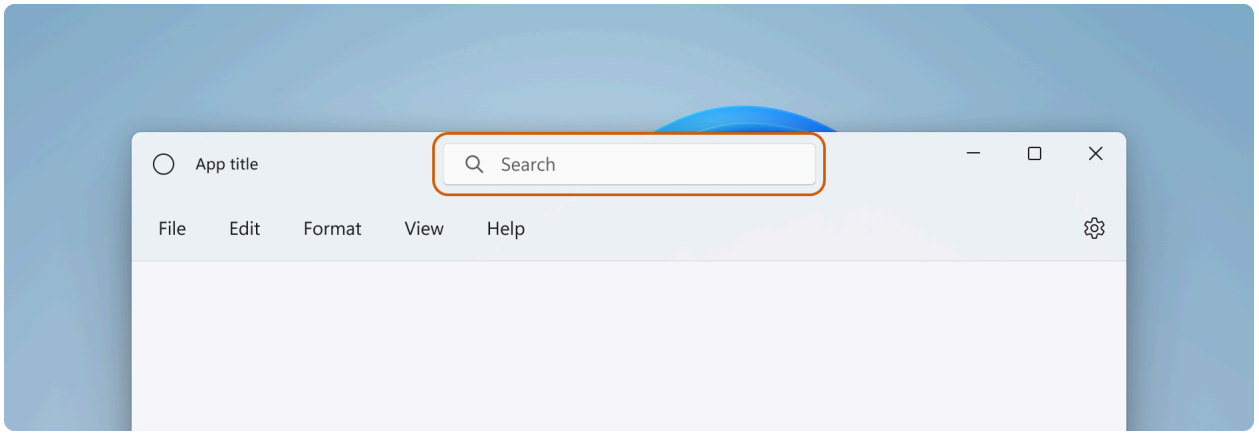
```
TitleBarTextBlock.Text = AppInfo.Current.DisplayInfo.DisplayName;
```

When you extend your content into the title bar area, the system title bar is hidden and a default AppWindowTitleBar is created that provides caption buttons and a drag region across the width of the screen, identical to the system title bar. If you don't place interactive content in your title bar, you can leave this default drag region as-is. If you place interactive content in your title bar, you need to specify the regions that are interactive, which we cover in the next section.

> **⊗ Caution**
>
> When you define custom drag regions, they don't have to be at the top of the window in the default title bar area; you can define any part of your UI as a drag region. However, placing drag regions in different places might make it difficult for your users to discover them.

Interactive content

You can place interactive controls, like buttons, menus, or a search box, in the top part of the app so they appear to be in the title bar. However, you need to specify which regions are interactive to ensure that your interactive elements receive user input while still allowing users to move your window around.



When you add interactive content in the title bar area, you need to use the InputNonClientPointerSource class to specify areas where input is passed through to the interactive control, rather than handled by the title bar. To set the interactive regions, call the InputNonClientPointerSource.SetRegionRects method. This method takes a value that specifies the kind of region being set (in this case, `Passthrough`), and an array of rectangles, each of which defines a `Passthrough` region. When the size of the title bar changes, you need to recalculate the interactive regions to match the new size, and call `SetRegionRects` with the new values.

This example shows a custom title bar UI with a search box and a PersonPicture account control. It demonstrates how to calculate and set the interactive rectangles for these controls so that input is passed through to them.

Here are a few important points to notice about this code:

- Set the `AppTitleBar` Grid height to 48 to follow the Title bar design guidance for interactive content.
- Set PreferredHeightOption to `Tall` so the caption buttons are the same height as the title bar.
- To make resizing controls and calculating regions easier, use a `Grid` with multiple named columns for the layout.
- Use *star* (*) sizing with `MinWidth` for the column that contains the `AutoSuggestBox` so that it will automatically resize with the window.
- Set `MinWidth` on the `RightDragColumn` to reserve a small area that is always draggable even when the window is resized.

- Set `ExtendsContentIntoTitleBar` to `true` in the MainWindow constructor. If you set it in code that gets called later, the default system title bar might be shown first, and then hidden.
- Make the initial call to calculate interactive regions after the `AppTitleBar` element has loaded. Otherwise, there's no guarantee that the elements used for the calculation will have their correct values.
- Update the interactive rectangle calculations only after the `AppTitleBar` element has changed size (`AppTitleBar_SizeChanged`). If you depend on the window `Changed` event, there will be situations (like window maximize/minimize) where the event occurs before `AppTitleBar` is resized and the calculations will use incorrect values.
- Set your custom drag/interactive areas only after you check `ExtendsContentIntoTitleBar` to confirm that a custom title bar is being used.

XAML

```
<Grid x:Name="AppTitleBar"
      Height="48">
    <Grid.ColumnDefinitions>
        <ColumnDefinition x:Name="LeftPaddingColumn" Width="0"/>
        <ColumnDefinition x:Name="IconColumn" Width="Auto"/>
        <ColumnDefinition x:Name="TitleColumn" Width="Auto"/>
        <ColumnDefinition x:Name="LeftDragColumn" Width="*"/>
        <ColumnDefinition x:Name="SearchColumn" Width="4*" MinWidth="220"/>
        <ColumnDefinition x:Name="RightDragColumn" Width="*" MinWidth="48"/>
        <ColumnDefinition x:Name="AccountColumn" Width="Auto"/>
        <ColumnDefinition x:Name="RightPaddingColumn" Width="0"/>
    </Grid.ColumnDefinitions>
    <Image x:Name="TitleBarIcon"
           Source="ms-appx:///Assets/StoreLogo.png"
           Grid.Column="1"
           Width="16" Height="16"
           Margin="8,0,4,0"/>
    <TextBlock x:Name="TitleBarTextBlock"
               Text="App title"
               Style="{StaticResource CaptionTextBlockStyle}"
               Grid.Column="2"
               VerticalAlignment="Center">
    </TextBlock>
    <AutoSuggestBox x:Name="TitleBarSearchBox"
                    Grid.Column="4"
                    QueryIcon="Find"
                    PlaceholderText="Search"
                    VerticalAlignment="Center"
                    MaxWidth="600"/>
    <PersonPicture x:Name="PersonPic"
                   Grid.Column="6"
```

```
                    Height="32" Margin="0,0,16,0"/>
</Grid>
```

This code shows how to calculate and set the interactive regions that correspond to the AutoSuggestBox and PersonPicture controls.

C#

```
public sealed partial class MainWindow : Window
{
    public MainWindow()
    {
        this.InitializeComponent();

        // Assumes "this" is a XAML Window. In projects that don't use
        // WinUI 3 1.3 or later, use interop APIs to get the AppWindow.
        m_AppWindow = this.AppWindow;
        AppTitleBar.Loaded += AppTitleBar_Loaded;
        AppTitleBar.SizeChanged += AppTitleBar_SizeChanged;
        ExtendsContentIntoTitleBar = true;
        TitleBarTextBlock.Text = AppInfo.Current.DisplayInfo.DisplayName;
    }

    private void AppTitleBar_Loaded(object sender, RoutedEventArgs e)
    {
        if (ExtendsContentIntoTitleBar == true)
        {
            // Set the initial interactive regions.
            SetRegionsForCustomTitleBar();
        }
    }

    private void AppTitleBar_SizeChanged(object sender, SizeChangedEventArgs
e)
    {
        if (ExtendsContentIntoTitleBar == true)
        {
            // Update interactive regions if the size of the window changes.
            SetRegionsForCustomTitleBar();
        }
    }

    private void SetRegionsForCustomTitleBar()
    {
        // Specify the interactive regions of the title bar.

        double scaleAdjustment = AppTitleBar.XamlRoot.RasterizationScale;

        RightPaddingColumn.Width = new
GridLength(m_AppWindow.TitleBar.RightInset / scaleAdjustment);
        LeftPaddingColumn.Width = new
GridLength(m_AppWindow.TitleBar.LeftInset / scaleAdjustment);
```

```
        GeneralTransform transform =
TitleBarSearchBox.TransformToVisual(null);
        Rect bounds = transform.TransformBounds(new Rect(0, 0,

TitleBarSearchBox.ActualWidth,

TitleBarSearchBox.ActualHeight));
        Windows.Graphics.RectInt32 SearchBoxRect = GetRect(bounds,
scaleAdjustment);

        transform = PersonPic.TransformToVisual(null);
        bounds = transform.TransformBounds(new Rect(0, 0,
                                                    PersonPic.ActualWidth,

PersonPic.ActualHeight));
        Windows.Graphics.RectInt32 PersonPicRect = GetRect(bounds,
scaleAdjustment);

        var rectArray = new Windows.Graphics.RectInt32[] { SearchBoxRect,
PersonPicRect };

        InputNonClientPointerSource nonClientInputSrc =
            InputNonClientPointerSource.GetForWindowId(this.AppWindow.Id);
        nonClientInputSrc.SetRegionRects(NonClientRegionKind.Passthrough,
rectArray);
    }

    private Windows.Graphics.RectInt32 GetRect(Rect bounds, double scale)
    {
        return new Windows.Graphics.RectInt32(
            _X: (int)Math.Round(bounds.X * scale),
            _Y: (int)Math.Round(bounds.Y * scale),
            _Width: (int)Math.Round(bounds.Width * scale),
            _Height: (int)Math.Round(bounds.Height * scale)
        );
    }
}
```

⚠ Warning

`AppWindow` uses physical pixels for compatibility with UI frameworks that don't use logical coordinates. If you use WPF or WinUI 3, `RightInset`, `LeftInset`, and the values used to calculate regions need to be adjusted if the display scale is not 100%. In this example, we get a `scaleAdjustment` value to account for the display scale setting.

- For WinUI 3, use the XamlRoot.RasterizationScale property to get the scale adjustment.

- For WPF, you can handle the Window.DpiChanged event to get the NewDpi value and calculate the scale adjustment.

System caption buttons

The system reserves the upper-left or upper-right corner of the app window for the system caption buttons (minimize, maximize/restore, close). The system retains control of the caption button area to guarantee that minimum functionality is provided for dragging, minimizing, maximizing, and closing the window. The system draws the Close button in the upper-right for left-to-right languages and the upper-left for right-to-left languages.

You can draw content underneath the caption control area, such as your app background, but you should not put any UI that you expect the user to be able to interact with. It does not receive any input because input for the caption controls is handled by the system.

These lines from the previous example show the padding columns in the XAML that defines the title bar. Using padding columns instead of margins ensures that the background paints the area under the caption control buttons (for transparent buttons). Using both right and left padding columns ensures that your title bar behaves correctly in both right-to-left and left-to-right layouts.

XAML

```
<Grid.ColumnDefinitions>
    <ColumnDefinition x:Name="LeftPaddingColumn" Width="0"/>
    <ColumnDefinition/>
    <ColumnDefinition x:Name="RightPaddingColumn" Width="0"/>
</Grid.ColumnDefinitions>
```

The dimensions and position of the caption control area is communicated by the AppWindowTitleBar class so that you can account for it in the layout of your title bar UI. The width of the reserved region on each side is given by the LeftInset or RightInset properties, and its height is given by the Height property.

Here's how the width of the padding columns is specified when the drag regions are calculated and set.

C#

```
RightPaddingColumn.Width =
    new GridLength(m_AppWindow.TitleBar.RightInset / scaleAdjustment);
```

```
LeftPaddingColumn.Width =
    new GridLength(m_AppWindow.TitleBar.LeftInset / scaleAdjustment);
```

> **ⓘ Important**
>
> See important information in the ***Interactive content*** section about how display scaling affects these values.

Tall title bar support for custom title bars

When you add interactive content like a search box or person picture in the title bar, we recommend that you increase the height of your title bar to provide more room for these elements. A taller title bar also makes touch manipulation easier. The AppWindowTitleBar.PreferredHeightOption property gives you the option of increasing your title bar height from the standard height, which is the default, to a taller height. When you select `Tall` title bar mode, the caption buttons that the system draws as an overlay in the client area are rendered taller with their min/max/close glyphs centered. If you haven't specified a drag region, the system will draw one that extends the width of your window and the height determined by the `PreferredHeightOption` value that you set.

This example shows how you can set the `PreferredHeightOption` property.

C#

```
// A taller title bar is only supported when drawing a fully custom title
bar.
if (ExtendsContentIntoTitleBar == true)
{
    m_AppWindow.TitleBar.PreferredHeightOption = TitleBarHeightOption.Tall;
}
```

> **⊗ Caution**
>
> The **AppWindowTitleBar.ExtendsContentIntoTitleBar** property must be `true` before you set the `PreferredHeightOption` property. If you attempt to set `PreferredHeightOption` while `ExtendsContentIntoTitleBar` is `false`, an exception is thrown.

Color and transparency in caption buttons

When you extend your app content into the title bar area, you can make the background of the caption buttons transparent to let your app background show through. You typically set the background to Colors.Transparent for full transparency. For partial transparency, set the alpha channel for the Color you set the property to.

These title bar properties can be transparent:

- ButtonBackgroundColor
- ButtonHoverBackgroundColor
- ButtonPressedBackgroundColor
- ButtonInactiveBackgroundColor

All other color properties will continue to ignore the alpha channel. If `ExtendsContentIntoTitleBar` is set to `false`, the alpha channel is always ignored for all `AppWindowTitleBar` color properties.

The button background color is not applied to the Close button *hover* and *pressed* states. The close button always uses the system-defined color for those states.

> **Tip**
>
> Mica is a delightful material that helps distinguish the window that's in focus. We recommend it as the background for long-lived windows in Windows 11. If you have applied Mica in the client area of your window, you can extend it into the title bar area and make your caption buttons transparent for the Mica to show through. See Mica material for more info.

Dim the title bar when the window is inactive

You should make it obvious when your window is active or inactive. At a minimum, you should change the color of the text, icons, and buttons in your title bar.

For XAML apps, handle the Window.Activated event to determine the activation state of the window, and update your title bar UI as needed.

C#

```
public MainWindow()
{
    ...
    Activated += MainWindow_Activated;
}

private void MainWindow_Activated(object sender, WindowActivatedEventArgs
```

```
args)
{
    if (args.WindowActivationState == WindowActivationState.Deactivated)
    {
        TitleBarTextBlock.Foreground =

(SolidColorBrush)App.Current.Resources["WindowCaptionForegroundDisabled"];
    }
    else
    {
        TitleBarTextBlock.Foreground =

(SolidColorBrush)App.Current.Resources["WindowCaptionForeground"];
    }
}
```

For other UI frameworks, handle an event to determine the activation state of the window, and update your title bar UI as needed. How you determine the state of the window depends on the UI framework you use for your app.

- **Win32**: Listen and respond to the WM_ACTIVATE message.
- **WPF**: Handle Window.Activated, Window.Deactivated.
- **WinForms**: Handle Form.Activated, Form.Deactivate.

Reset the title bar

To reset or switch to the system title bar while your app is running, you can call AppWindowTitleBar.ResetToDefault.

C#

```
m_AppWindow.TitleBar.ResetToDefault();
```

For XAML apps, you can also reset the title bar is these ways:

- Call SetTitleBar to switch to a new title bar element while your app is running.
- Call `SetTitleBar` with `null` as the parameter to reset to the default `AppWindowTitleBar` drag regions.
- Call `SetTitleBar` with `null` as the parameter and set ExtendsContentIntoTitleBar to `false` to revert to the default system title bar.

Show and hide the title bar

If you add support for *full screen* or *compact overlay* modes to your app, you might need to make changes to your title bar when your app switches between these modes. The

XAML Window does not provide any APIs to support full screen mode; you can use AppWindow APIs for this.

When your app runs in *full screen* mode, the system hides the title bar and caption control buttons. You can handle the AppWindow.Changed event and check the event args DidPresenterChange property to determine if you should show, hide, or change the title bar in response to a new window presentation.

This example shows how to handle the `Changed` event to show and hide the `AppTitleBar` element from previous examples. If the window is put in *compact overlay* mode, the title bar is reset to the default system title bar (or you could provide a custom title bar optimized for compact overlay).

C#

```
public MainWindow()
{
    this.InitializeComponent();

    m_AppWindow = this.AppWindow;
    m_AppWindow.Changed += AppWindow_Changed;
}

private void AppWindow_Changed(AppWindow sender, AppWindowChangedEventArgs
args)
{
    if (args.DidPresenterChange)
    {
        switch (sender.Presenter.Kind)
        {
            case AppWindowPresenterKind.CompactOverlay:
                // Compact overlay - hide custom title bar
                // and use the default system title bar instead.
                AppTitleBar.Visibility = Visibility.Collapsed;
                sender.TitleBar.ResetToDefault();
                break;

            case AppWindowPresenterKind.FullScreen:
                // Full screen - hide the custom title bar
                // and the default system title bar.
                AppTitleBar.Visibility = Visibility.Collapsed;
                sender.TitleBar.ExtendsContentIntoTitleBar = true;
                break;

            case AppWindowPresenterKind.Overlapped:
                // Normal - hide the system title bar
                // and use the custom title bar instead.
                AppTitleBar.Visibility = Visibility.Visible;
                sender.TitleBar.ExtendsContentIntoTitleBar = true;
                break;
```

```
            default:
                // Use the default system title bar.
                sender.TitleBar.ResetToDefault();
                break;
        }
    }
}
```

> **Note**
>
> *Full screen* and *compact overlay* modes can be entered only if supported by your app. See Manage app windows, FullScreenPresenter, and CompactOverlayPresenter for more info.

Do's and don'ts

- Do make it obvious when your window is active or inactive. At a minimum, change the color of the text, icons, and buttons in your title bar.
- Do define a drag region along the top edge of the app canvas. Matching the placement of system title bars makes it easier for users to find.
- Do define a drag region that matches the visual title bar (if any) on the app's canvas.

Full customization example

This examples shows all the code described in the Full customization section.

XAML

```

                    // and use the custom title bar instead.
                    AppTitleBar.Visibility = Visibility.Visible;
                    sender.TitleBar.ExtendsContentIntoTitleBar = true;
                    break;

                default:
                    // Use the default system title bar.
                    sender.TitleBar.ResetToDefault();
                    break;
            }
        }
    }

    private void SwitchPresenter(object sender, RoutedEventArgs e)
```

```
    {
        if (AppWindow != null)
        {
            AppWindowPresenterKind newPresenterKind;
            switch ((sender as Button).Name)
            {
                case "CompactoverlaytBtn":
                    newPresenterKind =
AppWindowPresenterKind.CompactOverlay;
                    break;

                case "FullscreenBtn":
                    newPresenterKind = AppWindowPresenterKind.FullScreen;
                    break;

                case "OverlappedBtn":
                    newPresenterKind = AppWindowPresenterKind.Overlapped;
                    break;

                default:
                    newPresenterKind = AppWindowPresenterKind.Default;
                    break;
            }

            // If the same presenter button was pressed as the
            // mode we're in, toggle the window back to Default.
            if (newPresenterKind == AppWindow.Presenter.Kind)
            {
                AppWindow.SetPresenter(AppWindowPresenterKind.Default);
            }
            else
            {
                // Else request a presenter of the selected kind
                // to be created and applied to the window.
                AppWindow.SetPresenter(newPresenterKind);
            }
        }
    }
}
```

Display WinRT UI objects that depend on CoreWindow

Article • 03/01/2023

Certain pickers, popups, dialogs, and other Windows Runtime (WinRT) objects depend on a CoreWindow; typically to display a user-interface (UI). Even though **CoreWindow** isn't supported in desktop apps (see Core unsupported classes), you can still use many of those WinRT classes in your desktop app by adding a little bit of interoperation code.

Your desktop app can be WinUI 3, Windows Presentation Foundation (WPF), or Windows Forms (WinForms) apps. Code examples are presented in C# and C++/WinRT.

Set the owner window handle (HWND) for a WinRT UI object

For classes that implement the **IInitializeWithWindow** interface (or the equivalent **IDataTransferManagerInterop** interface), you can use that interface to set an owner window on the object before you display it. It's a two-step process.

1. Decide which window will be the owner of the UI object that you want to display, and retrieve that window's HWND. For more details and code examples for this step, see Retrieve a window handle (HWND).
2. Then call the appropriate interoperatability API (for C# or C++/WinRT) to set an owner window handle (HWND) for the WinRT UI object.

For classes that implement IInitializeWithWindow

These classes implement **IInitializeWithWindow**:

- **Windows.ApplicationModel.Contacts.PinnedContactManager**
- **Windows.ApplicationModel.Payments.PaymentMediator**
- **Windows.Devices.Enumeration.DevicePicker**
- **Windows.Graphics.Capture.GraphicsCapturePicker**
- **Windows.Media.Casting.CastingDevicePicker**
- **Windows.Media.DialProtocol.DialDevicePicker**
- **Windows.Networking.NetworkOperators.ProvisioningAgent**
- **Windows.Security.Authentication.OnlineId.OnlineIdAuthenticator**

- Windows.Services.Store.StoreContext
- Windows.Storage.Pickers.FileOpenPicker
- Windows.Storage.Pickers.FileSavePicker
- Windows.Storage.Pickers.FolderPicker
- Windows.System.FolderLauncherOptions—Windows 10, version 1903 (10.0; Build 18362) and later
- Windows.System.LauncherOptions—Windows 10, version 1903 (10.0; Build 18362) and later
- Windows.UI.Core.CoreWindowDialog
- Windows.UI.Core.CoreWindowFlyout
- Windows.UI.Popups.MessageDialog. But for new apps we recommend using the ContentDialog control instead.
- Windows.UI.Popups.PopupMenu
- Windows.UI.StartScreen.SecondaryTile
- Windows.Web.Http.Filters.HttpBaseProtocolFilter

> ⓘ Note
>
> The list above is necessarily incomplete—refer to a type's documentation to see whether it implements **IInitializeWithWindow** (or an equivalent interop interface).

The next sections contain code examples to display a FolderPicker. But it's the same technique to display any of the APIs listed above.

WinUI 3 with C# (also WPF/WinForms with .NET 6 or later)

> ⓘ Note
>
> The code examples in this section use the **WinRT.Interop.WindowNative** C# interop class. If you target .NET 6 or later, then you can use that class in a WPF or WinForms project. For info about setting up your project to do that, see Call interop APIs from a .NET app.

The C# code below expects that you've already used the pattern documented in Retrieve a window handle (HWND). Then, to set the owner window for the UI object that you want to display, the code calls the **Initialize** method on the **WinRT.Interop.InitializeWithWindow** C# interop class. For more info about the C# interop classes, see Call interop APIs from a .NET app.

C#

```
// MainWindow.xaml.cs
private async void ShowFolderPickerAsync(IntPtr hWnd)
{
    // Create a folder picker.
    var folderPicker = new Windows.Storage.Pickers.FolderPicker();

    // Initialize the folder picker with the window handle (HWND).
    WinRT.Interop.InitializeWithWindow.Initialize(folderPicker, hWnd);

    // Use the folder picker as usual.
    folderPicker.FileTypeFilter.Add("*");
    var folder = await folderPicker.PickSingleFolderAsync();
}
```

WinUI 3 with C++

The C++/WinRT code below expects that you've already used the pattern documented in Retrieve a window handle (HWND). Then, to set the owner window for the UI object that you want to display, the code calls the interoperatability method **IInitializeWithWindow::Initialize**.

C++/WinRT

```
// pch.h
...
#include <microsoft.ui.xaml.window.h>
#include <Shobjidl.h>
#include <winrt/Windows.Storage.Pickers.h>

// MainWindow.xaml.cpp
winrt::fire_and_forget ShowFolderPickerAsync(HWND hWnd)
{
    // Create a folder picker.
    Windows::Storage::Pickers::FolderPicker folderPicker;

    // Initialize the folder picker with the window handle (HWND).
    auto initializeWithWindow{ folderPicker.as<::IInitializeWithWindow>() };
    initializeWithWindow->Initialize(hWnd);

    // Use the folder picker as usual.
    folderPicker.FileTypeFilter().Append(L"*");
    auto folder{ co_await folderPicker.PickSingleFolderAsync() };
}
```

For classes that implement IDataTransferManagerInterop

The **Windows.ApplicationModel.DataTransfer.DataTransferManager** class implements the **IDataTransferManagerInterop** interface (which, like **IInitializeWithWindow**, lets you set an owner window).

In a desktop app, instead of calling the **DataTransferManager.ShowShareUI** method, you call **IDataTransferManagerInterop::ShowShareUIForWindow**, as shown in the code examples below.

WinUI 3 with C# (also WPF/WinForms with .NET 6 or later)

C#

```
// MainWindow.xaml.cs
...
public sealed partial class MainWindow : Window
{
    ...

    [System.Runtime.InteropServices.ComImport]
    [System.Runtime.InteropServices.Guid("3A3DCD6C-3EAB-43DC-BCDE-
45671CE800C8")]
    [System.Runtime.InteropServices.InterfaceType(

System.Runtime.InteropServices.ComInterfaceType.InterfaceIsIUnknown)]
    interface IDataTransferManagerInterop
    {
        IntPtr GetForWindow([System.Runtime.InteropServices.In] IntPtr
appWindow,
            [System.Runtime.InteropServices.In] ref Guid riid);
        void ShowShareUIForWindow(IntPtr appWindow);
    }

    static readonly Guid _dtm_iid =
        new Guid(0xa5caee9b, 0x8708, 0x49d1, 0x8d, 0x36, 0x67, 0xd2, 0x5a,
0x8d, 0xa0, 0x0c);

    private void myButton_Click(object sender, RoutedEventArgs e)
    {
        // Retrieve the window handle (HWND) of the current WinUI 3 window.
        var hWnd = WinRT.Interop.WindowNative.GetWindowHandle(this);

        IDataTransferManagerInterop interop =
        Windows.ApplicationModel.DataTransfer.DataTransferManager.As
            <IDataTransferManagerInterop>();
```

```
        IntPtr result = interop.GetForWindow(hWnd, _dtm_iid);
        var dataTransferManager = WinRT.MarshalInterface

<Windows.ApplicationModel.DataTransfer.DataTransferManager>.FromAbi(result);

        dataTransferManager.DataRequested += (sender, args) =>
        {
            args.Request.Data.Properties.Title = "In a desktop app...";
            args.Request.Data.SetText("...display WinRT UI objects that
depend on CoreWindow.");
            args.Request.Data.RequestedOperation =

Windows.ApplicationModel.DataTransfer.DataPackageOperation.Copy;
        };

        // Show the Share UI
        interop.ShowShareUIForWindow(hWnd);
    }
}
...
```

WinUI 3 with C++

C++/WinRT

```
// pch.h in a Windows App SDK app
...
#include <shobjidl_core.h>
#include <microsoft.ui.xaml.window.h>
#include <winrt/Windows.ApplicationModel.DataTransfer.h>
...

// MainWindow.xaml.cpp
...
void MainWindow::myButton_Click(IInspectable const&, RoutedEventArgs const&)
{
    // Retrieve the window handle (HWND) of the current WinUI 3 window.
    auto windowNative{ this->m_inner.as<::IWindowNative>() };
    HWND hWnd{ 0 };
    windowNative->get_WindowHandle(&hWnd);

    winrt::com_ptr<IDataTransferManagerInterop> interop =

winrt::get_activation_factory<Windows::ApplicationModel::DataTransfer::DataT
ransferManager,
        IDataTransferManagerInterop>();

    winrt::guid _dtm_iid{ 0xa5caee9b, 0x8708, 0x49d1, { 0x8d, 0x36, 0x67,
0xd2, 0x5a, 0x8d, 0xa0, 0x0c } };
    Windows::ApplicationModel::DataTransfer::DataTransferManager
dataTransferManager{ nullptr };
    interop->GetForWindow(hWnd, _dtm_iid,
```

```
winrt::put_abi(dataTransferManager));

    dataTransferManager.DataRequested([]
(Windows::ApplicationModel::DataTransfer::DataTransferManager const& /*
sender */,
        Windows::ApplicationModel::DataTransfer::DataRequestedEventArgs
const& args)
    {
        args.Request().Data().Properties().Title(L"In a desktop app...");
        args.Request().Data().SetText(L"...display WinRT UI objects that
depend on CoreWindow.");

args.Request().Data().RequestedOperation(Windows::ApplicationModel::DataTran
sfer::DataPackageOperation::Copy);
    });

    interop->ShowShareUIForWindow(hWnd);
}
...
```

For classes that implement IUserConsentVerifierInterop

The **Windows.Security.Credentials.UI.UserConsentVerifier** class implements the **IUserConsentVerifierInterop** interface (which, like **IInitializeWithWindow**, lets you set an owner window).

In a desktop app, instead of calling the **UserConsentVerifier.RequestVerificationAsync** method:

- **C#**. Call the **RequestVerificationForWindowAsync** method of the **Windows.Security.Credentials.UI.UserConsentVerifierInterop** C# interop class. For more info about the C# interop classes, see Call interop APIs from a .NET app.
- **C++/WinRT**. Call **IUserConsentVerifierInterop::RequestVerificationForWindowAsync**.

For more info, and code examples, see **UserConsentVerifier**.

For classes that implement other interop interfaces

These interfaces have **XxxForWindow** methods, which let you set an owner window handle (HWND). You can use these interfaces directly from C++/WinRT. Versions of the

interfaces also exist in the form of C# classes—for more details, see Call interop APIs from a .NET app.

- IAccountsSettingsPaneInterop
- IDragDropManagerInterop
- IInputPaneInterop
- IPlayToManagerInterop
- IPrintManagerInterop
- IRadialControllerConfigurationInterop
- IRadialControllerIndependentInputSourceInterop
- IRadialControllerInterop
- ISpatialInteractionManagerInterop
- ISystemMediaTransportControlsInterop
- IUIViewSettingsInterop
- IWebAuthenticationCoreManagerInterop

Choose the right visual tree viewer for your Windows app

Article • 03/03/2025

A visual tree viewer, also known as a UI visualizer, is a tool used to inspect and interact with UI components in a Windows app at run time.

This can be helpful for prototyping, improving user experiences, and debugging UI issues through capabilities such as viewing and traversing component hierarchy, component highlighting, getting and setting state, and deep-linking to associated code.

Recommended tools

The following table identifies several UI visualization tools and the UI frameworks and Windows app platforms they support. A summary of each tool can be found after the table.

Expand table

UI platform/framework	Visual Studio - Live Visual Tree	Spy++	Accessibility Insights	Chromium UI DevTools
WinUI in the Windows App SDK	**Supported**	Not supported	**Supported**	Not supported
WPF	**Supported**	Not supported	**Supported**	Not supported
React Native for Desktop	**Supported**	Not supported	**Supported**	**Supported**
.NET MAUI	**Supported**	Not supported	**Supported**	Not supported
WinForms	**Supported**	**Supported**	**Supported**	Not supported
WinUI 2 for UWP	**Supported**	Not supported	**Supported**	Not supported
Classic Visual Basic apps	Not supported	**Supported**	Not supported	Not supported
Classic Win32 apps	Not supported	**Supported**	Not supported	Not supported
Chromium-based apps	Not supported	Not supported	Not supported	**Supported**

Visual Studio - Live Visual Tree

The Live Visual Tree and Live Property Explorer features ship with Visual Studio and work in tandem to provide an interactive runtime view of the UI elements in your app.

When to use Live Visual Tree

Use these tools when building apps with WinUI in the Windows App SDK, WinUI 2 for UWP, WPF, .NET MAUI, WinForms, or React Native for Desktop.

- For more information on WinUI in the Windows App SDK, WinUI 2 for UWP, and WPF, see Inspect XAML properties while debugging.
- For more information on .NET MAUI, see Inspect the visual tree of a .NET MAUI app.

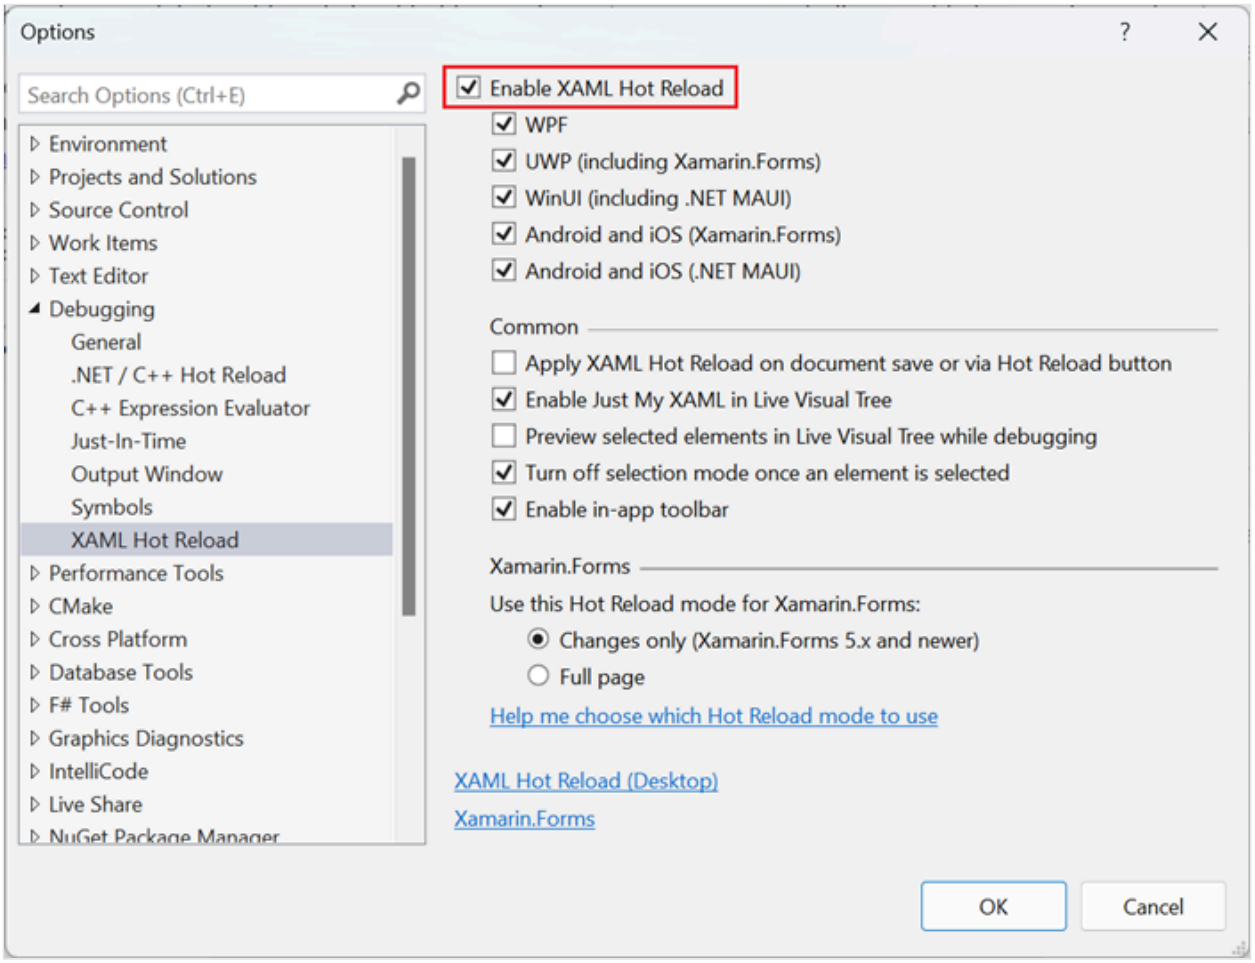
> **Note**
>
> The **WPF Tree Visualizer** is a legacy feature and is not in active development. You can use the WPF Tree visualizer to explore the visual tree of a WPF object, and to view the WPF dependency properties for the objects that are contained in that tree.

How to use Live Visual Tree

XAML Hot Reload must be enabled to view the Live Visual Tree (this feature is enabled by default in Visual Studio 2019 and later).

To check if XAML Hot Reload is enabled, run your app with the Visual Studio debugger attached (**F5** or **Debug -> Start Debugging**). When the app starts, you should see the in-app toolbar, which confirms that XAML Hot Reload is available (as shown in the following image).

If you don't see the in-app toolbar, select **Debug** > **Options** > **XAML Hot Reload** from the Visual Studio menu bar. In the **Options** dialog box, make sure that the **Enable XAML Hot Reload** option is selected.



Once your app is running in debug configuration (with the debugger attached), navigate to the Visual Studio menu bar (**Debug** > **Windows** > **Live Visual Tree**). This opens the Live Visual Tree pane with a real-time view of your XAML code.

By default, the **Just My XAML** option for the Live Visual Tree is selected. This provides a simplified view of the XAML element collection in your app and can be toggled on or off through the **Show Just My XAML** button as shown in the following image.

Capabilities of Live Visual Tree

The Live Visual Tree toolbar provides several options for selecting elements to examine through your application's UI at runtime.

- **Select Element in the Running Application**. With this mode on, when you select a UI element in the application, the Live Visual Tree automatically updates to show the node and it's properties in the tree corresponding to that element.

- **Display Layout Adorners in the Running Application**. With this mode on, the application window shows horizontal and vertical lines along the bounds of a selected object and a rectangle outlining its margins.

- **Preview selection**. With this mode on, Visual Studio shows the XAML where the element is declared (if you have access to the application source code).

Spy++

Spy++ (SPYXX.EXE) is a Win32-based utility that ships with Visual Studio and provides a graphical view of the system's processes, threads, windows, and window messages.

When to use Spy++

Use Spy++ when building a classic Win32 application or one that uses Win32 APIs to draw its UI elements, such as WinForms and Classic Visual Basic apps.

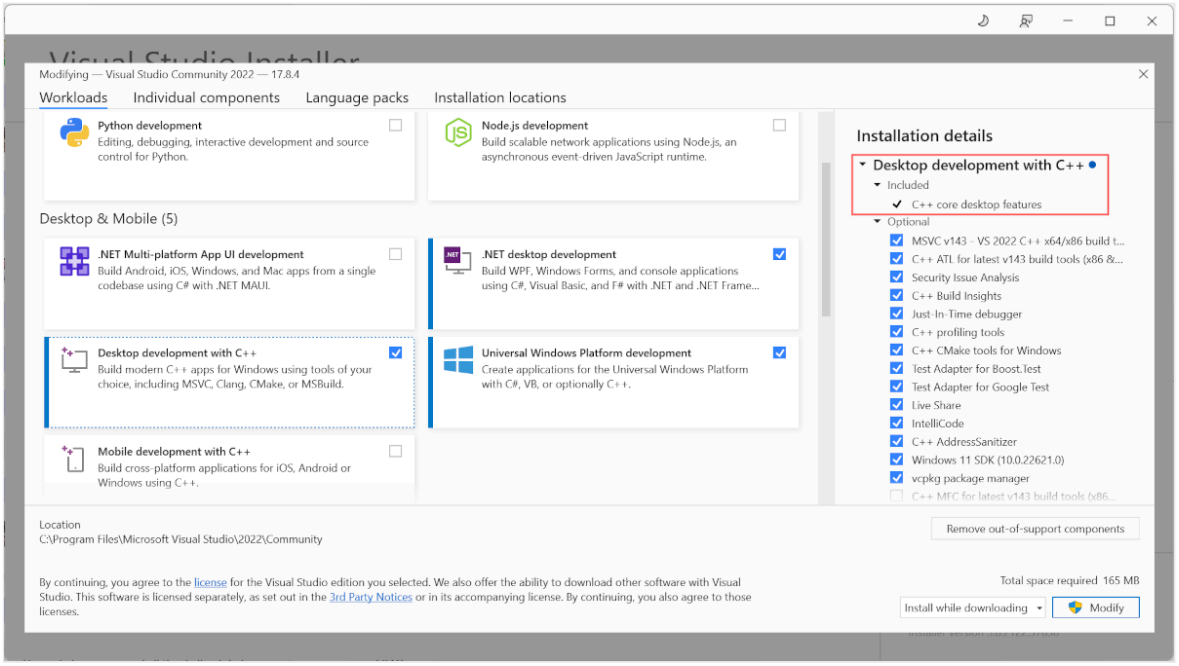
> **Note**
>
> For .NET framework apps, Spy++ is of limited usefulness as the window messages and classes intercepted by Spy++ don't correspond to managed events and property values.

How to use Spy++

Spy++ can be started from either Visual Studio or the Developer Command Prompt for Visual Studio.

To start Spy++ from Visual Studio:

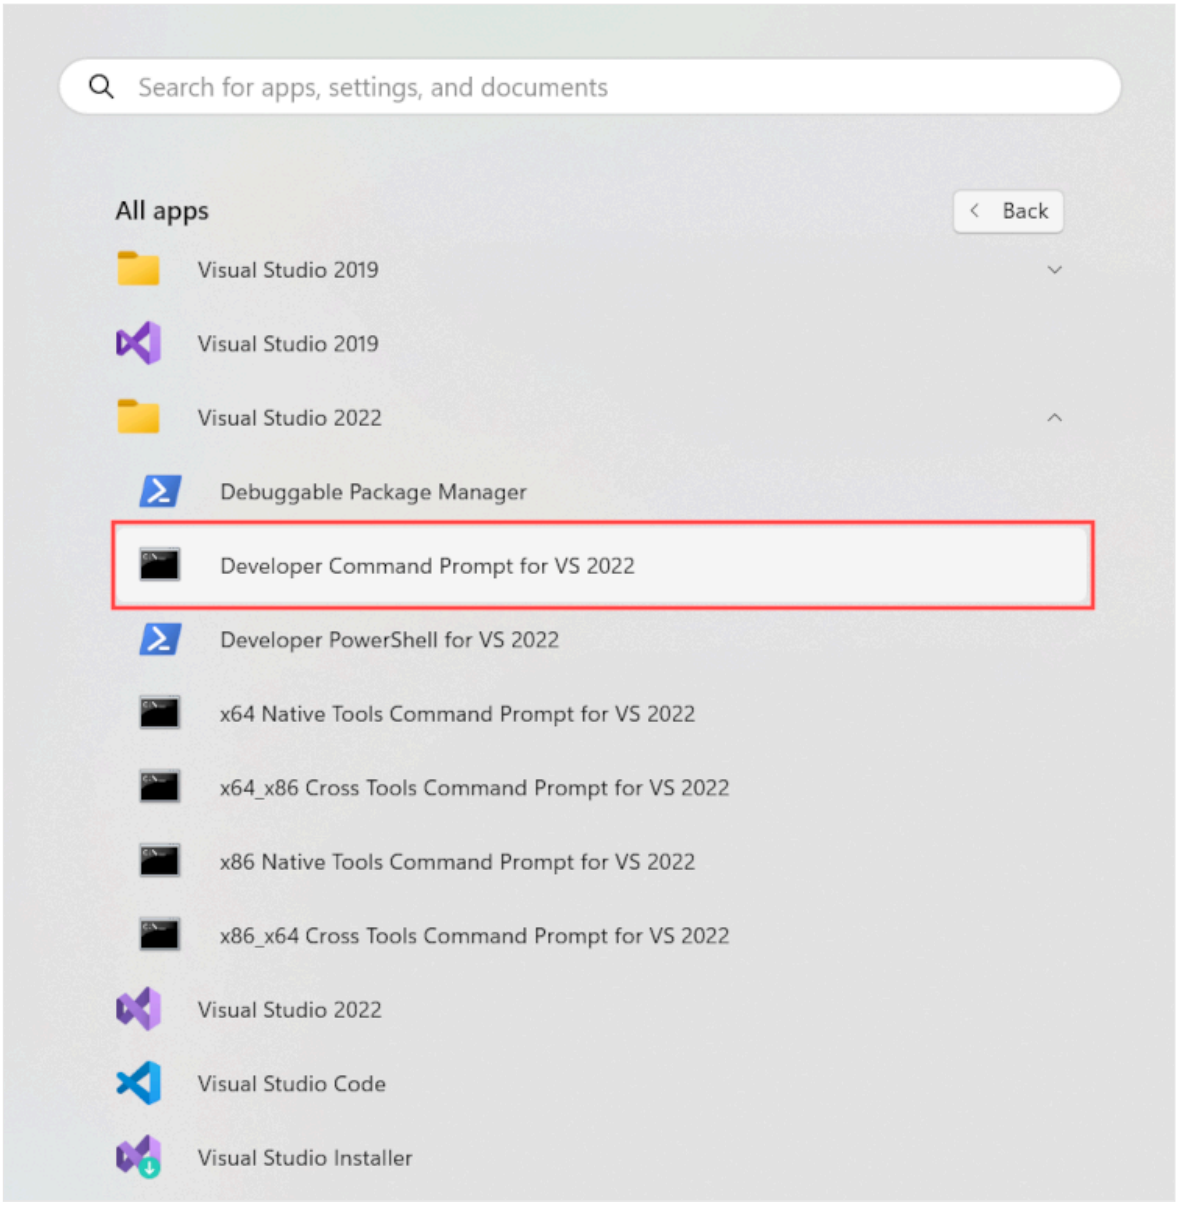
- Confirm that your Visual Studio installation includes the **C++ core desktop features** component from the **Desktop development with C++** workload. (This is installed by default with Visual Studio 2022.)



- When installed, Spy++ is available from the **Tools** menu.
- Spy++ runs independently of Visual Studio, which can be closed if no longer required.

To start Spy++ from the Developer Command Prompt for Visual Studio:

- Launch **Developer Command Prompt for Visual Studio** from the Windows **Start** menu.

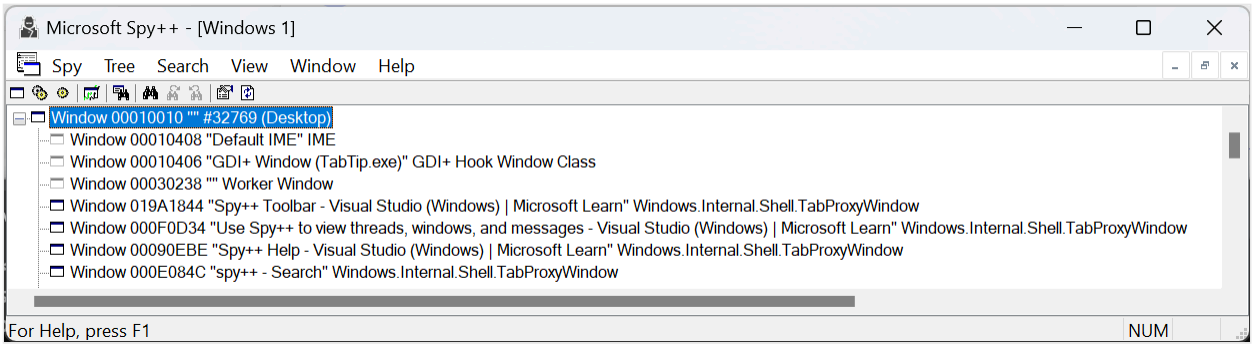


- At the command prompt, enter spyxx.exe (or spyxx_amd64.exe for the 64-bit version) and press Enter.

For more specific information on how to use Spy++ from Visual Studio, see Spy++ Toolbar.

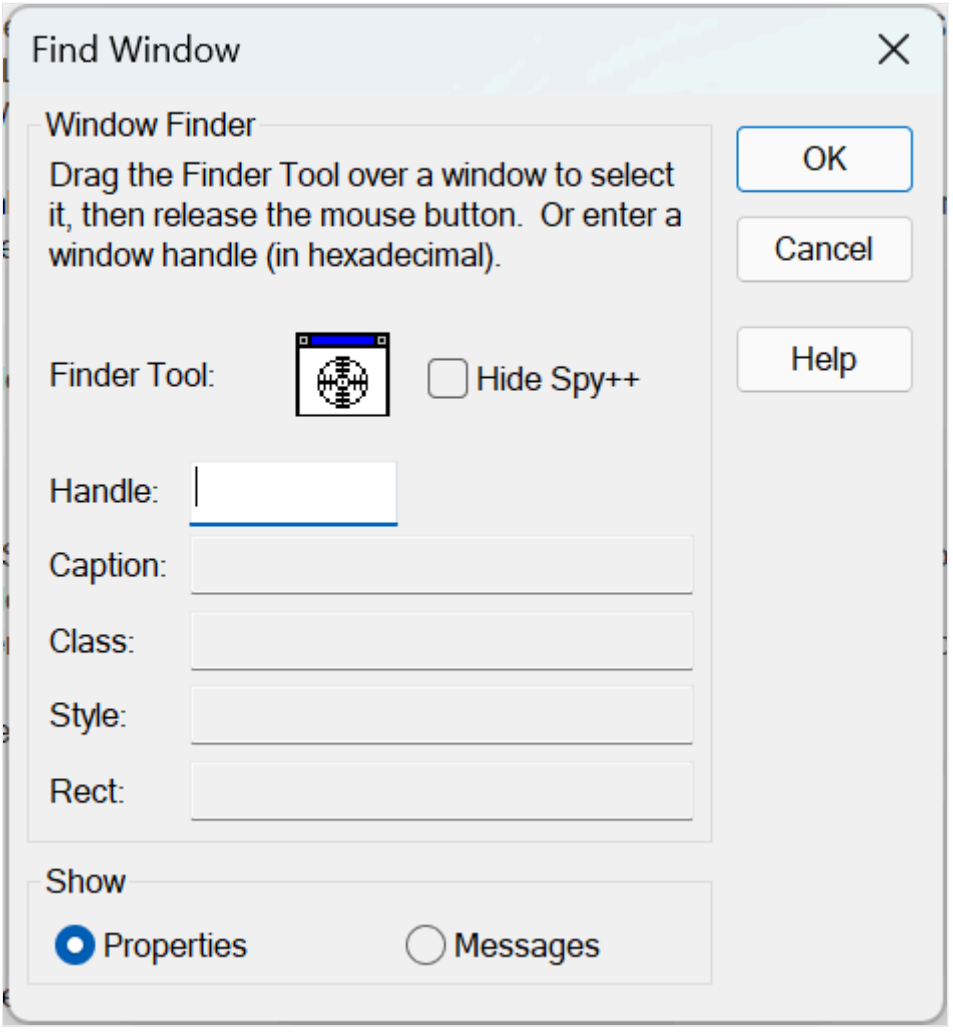
Capabilities of Spy++

Spy++ displays a graphical tree of relationships among system objects, with the current desktop window at the top of the tree and child nodes representing all other windows listed according to the standard window hierarchy. It can provide valuable insight into an application's behavior that is not available through the Visual C++ debugger.



With Spy++ you can:

- Search for specific windows, threads, processes, or messages.
- View the properties of selected threads processes or messages.
- Select a window, thread, process, or message directly in the tree view.
- Use the **Finder Tool** to select a window using the mouse pointer (**Search** -> **Find Window**).



- Set a message option by using a complex message log selection parameter.

For Spy++ documentation, see Spy++ Help.

Accessibility Insights for Windows - Live Inspect

Accessibility Insights for Windows - Live Inspect is a downloadable Microsoft application that can help developers find and fix accessibility issues in Windows apps that support UI Automation. It helps developers verify that an element in an app has the correct UI Automation properties simply by hovering over the element or setting keyboard focus to it.

When to use Accessibility Insights - Live Inspect

Live Inspect is typically used in conjunction with Live Visual Tree, Spy++, and other tools when building apps with WinUI in the Windows App SDK, WinUI 2 for UWP, WPF, .NET MAUI, WinForms, or React Native for Desktop.

How to use Accessibility Insights - Live Inspect

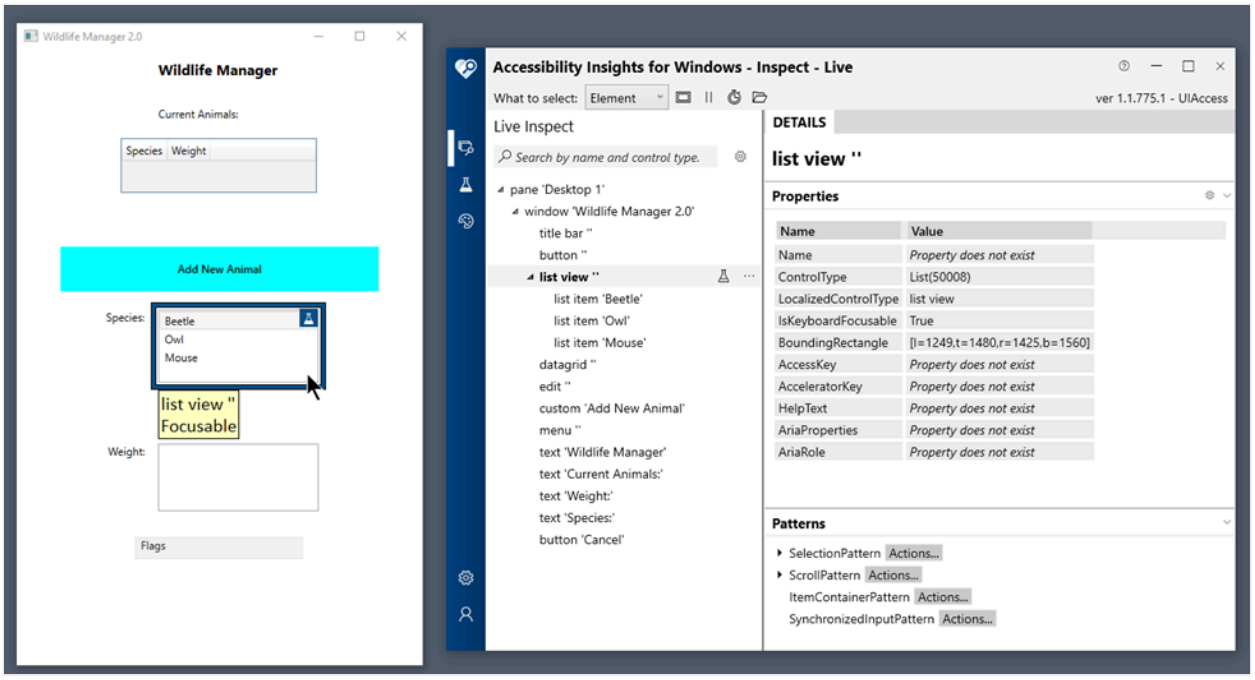
Accessibility Insights must be downloaded and installed from Download Accessibility Insights.

Capabilities of Accessibility Insights - Live Inspect

Live Inspect displays a graphical tree of relationships among system objects with detail panes containing the UI Automation properties and patterns corresponding to the selected element. The current desktop window is displayed at the top of the tree and child nodes representing all other windows listed according to the standard window hierarchy.

With Live Inspect you can:

- Verify that an element in an app has the right UI Automation properties simply by hovering over the element or setting keyboard focus on it.
- Visually highlights elements in the target application.
- Test controls or patterns with manual or automated checks for compliance with numerous accessibility rules and guidelines.



To learn more about UI Automation, see UI Automation Overview.

To learn more about Accessibility Insights, see Accessibility Insights for Windows

Chromium UI DevTools for Windows

Chromium UI DevTools for Windows is a tool from Google that lets you inspect the UI system like a webpage using the frontend DevTools Inspector.

When to use Chromium UI DevTools for Windows

Use Chrome UI DevTools if you're developing a Chromium project, including progressive web apps or Electron desktop apps. For more information on Electron, see the DevTools extension on GitHub.

How to use Chromium UI DevTools for Windows

The Chromium UI DevTools for Windows codebase must be downloaded from GitHub and built with Visual Studio. For more information, see the UI DevTools Overview.

Capabilities of Chromium UI DevTools for Windows

Chromium UI DevTools for Windows uses a webpage front end to display and traverse views, windows, and other UI elements.

With Chromium UI DevTools for Windows you can:

- Use a hierarchical UI element tree to inspect UI elements and their properties.
- Use Inspect mode, which highlights a UI element when you hover over it and reveals the element's nodes in the UI element tree.
- Use the Elements panel to open a search bar and find an element in the UI element tree using name, tag, and style properties.
- Use the Sources panel to open the class header file in Chromium code search and pull in the code from local files.

An overview of Package Identity in Windows apps

Article • 02/10/2023

Package identity is a unique identifier across space and time. Just as your DNA uniquely identifies you, package identity uniquely identifies a package.

A package has an associated set of bits (files etc). No two packages have the same identity, and any changes to the bits associated with a package requires a different identity.

What is package identity?

A package identity is a logical construct, uniquely identifying a package. The identity has 5 parts:

- **Name:** This is a name chosen by the app developer. The Microsoft Store enforces uniqueness of all app names across all app developers within the Store, but names are not guaranteed to be unique in the general ecosystem.
- **Version:** Version number of the package. The app developer can choose arbitrary version numbers but must ensure version numbers increase with updates.
- **Architecture:** The processor architecture being targeted by the package. The same app can be built targeting different processor architectures, with each build residing in its own package.
- **ResourceId:** A string chosen by the app developer to uniquely identify resource packages, for example different languages or different display scales. Resource packages are typically architecture-neutral. For bundles, the **ResourceId** is always `~`.
- **Publisher:** The app developer's subject name as identified by their signing certificate. This is theoretically unique for each app developer, because reputable certification authorities use unique real-world names and identities to populate the certificate's subject name field.

This construct is sometimes referred to as the *5-part tuple*.

> **Note**
>
> **Unsigned packages** (1) still require a **Publisher**, (2) the **Publisher** must contain the Unsigned marker (OID.2.25.311729368913984317654407730594956997722=1), (3)

the Unsigned marker *must* be the last field in the **Publisher** string, and (4) there is no certificate or signing for an Unsigned package.

Package identity fields limits

Field	Data type	Limits	Comments
Name	Package String	Min: 3 Max: 50	Allowed values per Validate API (see Package String)
Version	DotQuad	Min: 0.0.0.0 Max: 65535.65535.65535.65535	String form uses base-10 dotted notation, "Major.Minor.Build.Revision"
Architecture	Enumeration	Min: N/A Max: N/A	Allowed values are "neutral", "x86", "x64", "arm", "arm64", "x86a64"
ResourceId	Package String	Min: 0 Max: 30	Allowed values per Validate API (see Package String)
Publisher	String	Min: 1 Max: 8192	Allowed values per X.509
PublisherId	String	Min: 13 Max: 13	Base32 encoded, Crockford variant, i.e. [a-hjkmnp-tv-z0-9]

What is a 'Package String'?

A **package string** is a string that allows the following characters:

- Allowed Input Characters (ASCII subset)
  - Uppercase letters (U+0041 thru U+005A)
  - Lowercase letters (U+0061 thru U+007A)
  - Numbers (U+0030 thru U+0039)
  - Dot (U+002E)
  - Dash (U+002D)

The following values are prohibited from being used as package strings:

Condition	Prohibited values
Cannot equal	".", "..", "con", "prn", "aux", "nul", "com1", "com2", "com3", "com4", "com5", "com6", "com7", "com8", "com9", "lpt1", "lpt2", "lpt3", "lpt4", "lpt5", "lpt6", "lpt7", "lpt8", "lpt9"

Condition	Prohibited values
Cannot begin with	"con.", "prn.", "aux.", "nul.", "com1.", "com2.", "com3.", "com4.", "com5.", "com6.", "com7.", "com8.", "com9.", "lpt1.", "lpt2.", "lpt3.", "lpt4.", "lpt5.", "lpt6.", "lpt7.", "lpt8.", "lpt9.", "xn--"
Cannot end with	"."
Cannot contain	".xn--"

A **package string** must be compared using an ordinal case-insensitive string comparison APIs (e.g. _wcsicmp).

Package Identity's `name` and `resourceid` fields are package strings.

PackageId object

A PackageId is an object containing the 5-part tuple as individual fields (`Name`, `Version`, `Architecture`, `ResourceId`, `Publisher`).

Package Full Name

A **Package Full Name** is an opaque string derived from all 5 part of a package's identity (name, version, architecture, resourceid, publisher)

`<Name>_<Version>_<Architecture>_<ResourceId>_<PublisherId>`

For example, one package full name for the Windows Photos app is "Microsoft.Windows.Photos_2020.20090.1002.0_x64__8wekyb3d8bbwe", where "Microsoft.Windows.Photos" is the name, "2020.20090.1002.0" is the version number, "x64" is the target processor architecture, the resource ID is empty (no content between the last two underscores), and "8wekyb3d8bbwe" is the publisher ID for Microsoft.

The **Package Full Name** uniquely identifies an **MSIX** package or bundle. It is an error to have two packages or bundles with different contents but with the same Package Full Name.

> ⓘ **Note**
>
> **MSIX** is the new name for the previous term **APPX**. For more information, see **What is MSIX?**

Package Family Name

A **Package Family Name** is an opaque string derived from only two parts of a package identity - *name* and *publisher*:

`<Name>_<PublisherId>`

For example, the Package Family Name of the Windows Photos app is "Microsoft.Windows.Photos_8wekyb3d8bbwe", where "Microsoft.Windows.Photos" is the name and "8wekyb3d8bbwe" is the publisher ID for Microsoft.

Package Family Name is often referred to as a 'version-less Package Full Name'.

> ⓘ **Note**
>
> This isn't strictly true, as Package Family Name also lacks architecture and Resource ID.

> ⓘ **Note**
>
> Data and security are typically scoped to a package family. For example, it would be a poor experience if you configured the Notepad app installed from a Notepad version 1.0.0.0 package to enable Wordwrap. Then Notepad was subsequently updated to 1.0.0.1 and your configuration data wasn't carried over to the newer version of the package.

Publisher Id

A Package Family Name is a string with the format:

`<name>_<publisherid>`

where Publisher Id has some very specific properties:

- Derived from Publisher
- MinLength = MaxLength = 13 chars [fixed-size]
- Allowed Characters (as regex) = a-hj-km-np-tv-z0-9
  - Base-32, Crockford Variant, i.e. alphanumeric (A-Z0-9) except no I (eye), L (ell), O (oh) or U (you)
- Ordinal case-insensitive for comparisons --- ABCDEFABCDEFG == abcdefabcdefg

So you'll never see % : \ / " ? or other characters in a Publisher Id.

See PackageFamilyNameFromId and PackageNameAndPublisherIdFromFamilyName for more details.

Publisher Id is often referred to as PublisherId.

Why does Publisher Id exist?

Publisher Id exists because Publisher needs to match your cert's X.509 name/signer, thus:

- It can be very big (length <= 8192 chars)
- It can include characters that are awkward or restricted (backslash, etc.)

These issues can make some X.509 strings awkward or impossible to use in the filesystem, registry, URLs, and other contexts.

How do I create a PublisherId?

Use PackageNameAndPublisherIdFromFamilyName to extract the `PublisherId` from a `PackageFamilyName`.

Use PackageIdFromFullName to extract the `PublisherId` from a `PackageFullName`.

It's rare to need to create a `PublisherId` from `Publisher`, but it can be done with the use of available APIs:

C++

```
#include <appmodel.h>

HRESULT PublisherIdFromPublisher(
    _In_ PCWSTR publisher,
    _Out_writes_(PACKAGE_PUBLISHERID_MAX_LENGTH + 1) PWSTR publisherId)
{
    PCWSTR name{ L"xyz" };
    const size_t nameLength{ ARRAYSIZE(L"xyz") - 1 };
    const size_t offsetToPublisherId{ name + 1 }; // xyz_...publisherid...
    PACKAGE_ID id{};
    id.name = name;
    id.publisher = publisher;

    WCHAR familyName[PACKAGE_PUBLISHERID_MAX_LENGTH + 1]{};
    UINT32 n{ ARRAYSIZE(familyName) };
    RETURN_IF_WIN32_ERROR(PackageFamilyNameFromId(&id, &n, familyName);
    RETURN_IF_FAILED(StringCchCopyW(publisherId,
PACKAGE_PUBLISHERID_MAX_LENGTH + 1, familyName + offsetToPublisherId));
    return S_OK;
}
```

The following is a classic Windows C implementation of the same operation:

C

```
#include <appmodel.h>

HRESULT PublisherIdFromPublisher(
    _In_ PCWSTR publisher,
    _Out_writes_(PACKAGE_PUBLISHERID_MAX_LENGTH + 1) PWSTR publisherId)
{
    const WCHAR c_name[]{ L"xyz" };
    const UINT32 c_nameLength{ ARRAYSIZE(c_nameForPublisherToPublisherId) -
1 };

    PACKAGE_ID id{};
    id.name = c_name;
    id.publisher = publisher;
    WCHAR familyName[PACKAGE_PUBLISHERID_MAX_LENGTH + 1]{};
    UINT32 n{ ARRAYSIZE(familyName) };
    RETURN_IF_WIN32_ERROR(PackageFamilyNameFromId(&id, &n, familyName));
    RETURN_IF_FAILED(StringCchCopyW(publisherId,
PACKAGE_PUBLISHERID_MAX_LENGTH + 1,  familyName + c_nameLength + 1);
    return S_OK;
}
```

This creates the PublisherId by converting a Package Id to a Package Family Name with the resulting format `xyz_<publisherid>`. This recipe is stable and reliable.

This only requires you compile with appmodel.h from the SDK and link with kernel32.lib (or kernelbase.lib, onecore.lib, or api-ms-win-appmodel-runtime-l1.lib if using APIsets).

Understanding processor architecture in package identity

A common misunderstanding is that `Architecture=x64` means the package can only contain x64 code. This is not true. It means that the package works on systems supporting x64 code, and can be used by x64 apps. You could make a package containing only PDF files but declare it with `<Identity Architecture=x64...>` because it is only intended to be installed on x64-compatible systems (e.g. x64 packages can only be installed on x64 and (as of Windows 11) Arm64 systems, because x86, Arm, and Windows 10 Arm64 systems don't support x64).

Even more misunderstood, `Architecture=neutral` does *not* mean the package contains no executable code. It means the package works on all architectures. For example, you could make a package containing an AES encryption API written in JavaScript, Python,

C#, etc. but the performance is not acceptable on Arm64 systems. So, you include an optimized Arm64 binary and implement the API to handle it:

C++

```
void Encrypt(...)
{
    HANDLE h{};
    if (GetCpu() == arm64)
    {
        h = LoadLibrary(GetCurrentPackagePath() + "\bin\encrypt-arm64.dll")
        p = GetProcAddress(h, "Encrypt")
        return (*p)(...)
    }
    else
    {
        // ...call other implementation...
    }
}
```

Or you can make a neutral package with multiple variants:

YAML

```
\
    bin\
        encrypt-x86.dll
        encrypt-x64.dll
        encrypt-arm.dll
        encrypt-arm64.dll
```

Developers can then `LoadLibrary("bin\encrypt-" + cpu + ".dll")` to get the appropriate binary for their process at runtime.

Typically, neutral packages have no per-architecture content, but they can. There are limits to what one can do (e.g. you could make a Notepad package containing notepad.exe compiled for x86 + x64 + arm + arm64 but **appxmanifest.xml** can only declare `<Application Executable=...>` pointing to one of them). Given that there are bundles that let you install only the needed bits, this is a very uncommon thing to do. It's not illegal, just advanced and exotic.

Also, `Architecture=x86` (or x64|arm|arm64) doesn't mean the package only contains executable code for the specified architecture. It's just the overwhelmingly common case.

> ⓘ Note

When discussing "code" or "executable code" in this context, we are referring to portable executable (PE) files.

Is package identity case sensitive?

Mostly, no, but `Publisher` is case-sensitive.

The remaining fields (`Name`, `ResourceId`, `PublisherId`, `PackageFullName` and `PackageFamilyName`) are not. These fields will preserve case but compare case-insensitively.

PackageNameAndPublisherIdFromFamilyName

Windows apps: packaging, deployment, and process

Article • 08/19/2024

> **Note**
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

This topic discusses your options concerning:

- Whether or not your app will be packaged.
- How you'll deploy/distribute your app, and how it'll be installed.
- Your app's run-time process—how isolated it'll be; and what APIs will be available to it.

You can make those decisions for both new and existing apps. But if you're still in the planning stage for a new app, then before you start to think about the considerations above, first decide what development platform and user interface (UI) framework you'll use for your app. And for that decision, see An overview of Windows development options.

Packaged or unpackaged

The decision to make your app either packaged or unpackaged is first determined by a concept known as *package identity*, which we'll describe in this section. If you don't need that, then the decision comes down to the desired installer experience for yourself and for your users. Let's drill into the details of those things.

Many Windows extensibility features—including background tasks, notifications, live tiles, custom context menu extensions, and share targets—can be used by an app only if that app has package identity at runtime. That's because the operating system (OS) needs to be able to identify the caller of the corresponding API. See Features that require package identity.

- If you need to use any of those features, then your app needs package identity. And therefore it *needs* to be a packaged app (packaged apps are the only kind that

have package identity). A packaged app is packaged by using MSIX technology (see What is MSIX?).
    - For a new app, the packaging process is straightfoward (and at the end of this section there's info about how to do it).
    - For some existing apps, you can follow the same packaging process as for a new app. But because some existing apps aren't yet ready for all of their content to be present inside an MSIX package, there's an option for your app to be *packaged with external location*. That enables your app to have package identity; thereby being able to use those features that require it. For more info, see Grant package identity by packaging with external location.
- Even if you *don't* need to use any of those features, then creating a packaged app is still a good idea. It gives your users the easiest way to install, uninstall, and update your app. For more info, see Deployment/distribution/installation in this topic.
- But creating an unpackaged app is an option.

The takeaway is that packaged apps are the only kind that have package identity (and they have the best install experience). An unpackaged app doesn't have package identity; so it can't use the APIs/features mentioned above.

For more details about packaged versus unpackaged, see Deployment overview; in particular, the **Advantages and disadvantages of packaging your app** section in that topic. That topic also mentions the *packaged with external location* option.

For info about how to configure your app as packaged or unpackaged:

- **WinUI 3 apps (Windows App SDK)**. See the `AppxPackage` Visual Studio project property in Project properties; and see Create your first WinUI 3 (Windows App SDK) project.
- **Desktop apps**. See Set up your desktop app for MSIX packaging.
- **Universal Windows Platform (UWP) apps**. UWP apps are already configured as packaged; and that configuration can't be changed.

Also see the Windows Package Manager and the WinGet client section in this topic.

Deployment/distribution/installation

- A packaged app is packaged by using MSIX technology.
    - A packaged app is *installed* by using MSIX, also. But if you choose to *package with external location*, then you can think of that as a "bring-your-own-installer" model. So there *will* be some installer work for you to do with that option. For more info, see Grant package identity by packaging with external location.

- An unpackaged app doesn't involve MSIX at all.

So, why does it matter whether or not your app is packaged?

- Well, MSIX gives your users an easy way to install, uninstall, and update your app. Uninstall is clean—when your app is uninstalled, the system is restored to the same state it was in before installation; no artifacts are left behind.
- This kind of app also supports incremental and automatic updates.
- The Microsoft Store optimizes for apps of this kind (although they can be used in or out of the Store).
- It's an easy path for use via MSIX app attach (for Azure Virtual Desktop virtual machines). For more info, see What is MSIX app attach?.
- A signed package benefits from strong anti-tampering. This benefit is even greater than for an unpackaged app installed under **Program Files**.

Also see the Windows Package Manager and the WinGet client section in this topic.

AppContainer or Medium IL

The option to run your app in an AppContainer, or not, is a question of security. An AppContainer app's process and its child processes run inside a lightweight app container where they can access only the resources that are specifically granted to them. And they're isolated using file system and registry virtualization. As a result, apps implemented in an AppContainer can't be hacked to allow malicious actions outside of the limited assigned resources.

Packaged or unpackaged apps can be configured to run in an AppContainer. But the process is more straightforward for packaged apps. If an app isn't an AppContainer app, then it's a *Medium IL* app.

For more info, see AppContainer for legacy apps and MSIX AppContainer apps.

For info about how to configure your app to run in an AppContainer or Medium IL:

- **WinUI 3 apps (Windows App SDK)**. See the `uap10:TrustLevel` app package manifest attribute in Configure a WinUI 3 project for AppContainer.
- **Desktop apps**. See the `TrustLevel` Visual Studio project property in MSIX AppContainer apps (in the section that's appropriate for your kind of app).
- **Universal Windows Platform (UWP) apps**. UWP apps are already configured to run in an AppContainer; and that configuration can't be changed.

Remember that unpackaged apps don't have an app package manifest. So for unpackaged apps, you declare your AppContainer-or-Medium-IL decision in your

project file instead of in an app package manifest.

Win32 app isolation

> **Important**
>
> The feature described in this section is available in pre-release versions of the Windows Insider Preview.

Win32 app isolation is an upcoming security feature in Windows which, in the event of an app being compromised, helps contain the damage, and safeguard user privacy choices. This feature is built on the foundation of AppContainers and components that virtualize resources and provide brokered access to other resources. For documentation and tools to help you isolate your apps, see Welcome to the Win32 app isolation repo.

App capabilities

App capabilities (for example, internetClient, location, microphone, and bluetooth) are relevant mostly to *packaged apps that run in an AppContainer*. So that includes *all* Universal Windows Platform (UWP) apps, and *some* desktop apps.

But there are some scenarios where even a Medium IL app (that is, *not* an AppContainer app) should declare a capability. One example is the *runFullTrust* restricted capability.

For more details about app capabilities, what kinds of apps they apply to, and how to configure them, see App capability declarations. You configure capabilities in your app package manifest; and that's why they apply only to packaged apps.

Kinds of apps

Desktop apps and Universal Windows Platform (UWP) apps are the two main kinds of apps—although, there are several kinds of apps in the *desktop apps* family. Choosing a user interface (UI) framework—WinForms, WPF, Win32, Direct 2D/3D, UWP, or WinUI 3—is one option that's to some degree independent of the configurations described in this topic.

But let's take a look at how those app kinds can differ from one another in terms of packaging, deployment, and process.

First off, all UWP apps are packaged, and run in an AppContainer. But for desktop apps, things are more flexible. You can choose to package your desktop app, or not. And, independently of that decision, you can choose to configure your desktop app as either an AppContainer or a Medium IL app.

Expand table

	Packaged	Unpackaged
AppContainer	Desktop apps UWP apps	Desktop apps
Medium IL	Desktop apps	Desktop apps

For packaged apps, to configure the kind of app you want, you use the `uap10:RuntimeBehavior` attribute in your app package manifest (see Application (Windows 10)).

- **Desktop apps** are Windows `.exe`s, typically with a **main** or **WinMain** entry-point function. To configure your app as a desktop app, set `uap10:RuntimeBehavior` to either "packagedClassicApp" or "win32App".
  - The value "packagedClassicApp" indicates either a WinUI 3 app (Windows App SDK) or a Desktop Bridge app (Centennial). The difference is that a Centennial app runs in an AppContainer.
  - And "win32App" indicates any other kind of Win32 app (including an app packaged with external location).
- Lastly, setting `uap10:RuntimeBehavior` to "windowsApp" gives you a UWP app.

For all of the options for the kinds of apps you can develop, see Windows app development: options and features.

Windows App SDK—framework-dependent or self-contained

If you're developing or maintaining an app that makes use of the Windows App SDK, then you have a further decision to make. Because there are the following two ways in which you can deploy the Windows App SDK that your app depends on:

- Framework-dependent (the default). Your app needs the Windows App SDK runtime and/or Framework package to be present on the target machine.
- Self-contained. Your app carries with it its Windows App SDK dependencies.

For more info, see Windows App SDK deployment overview.

Windows Package Manager and the WinGet client

A package manager can help your users to install/upgrade/configure your software by automating the workflow. Package managers can help install any software, but they tend to be used mostly to install developer tools. So if you're building a developer tool, then you might be particuarly interested in this option. But here's how it works:

- You, as the software developer, define to the package manager (in the form of declarative instructions) all of the pieces necessary for a successful install of your product.
- And then when a user installs your software, the package manager follows your declarative instructions to automate the install-and-configure workflow.

The result is a reduction in time spent getting a user's environment ready, and better compatibility between the components installed. And you can use Windows Package Manager to distribute your packaged or unpackaged apps in formats such as `.msix`, `.msi`, and `.exe`.

For more info, see Windows Package Manager.

Features that require package identity

Article • 05/26/2023

Some modern Windows experiences require your app to have package identity at runtime (in other words, your app needs to be *packaged*). Those experiences include certain Windows features, certain Windows Runtime APIs, package extensions, and UWP components.

Universal Windows Platform (UWP) apps receive package identity by default because they can be distributed only via MSIX packages. Other types of Windows apps, including WPF apps, can also be deployed via MSIX packages to obtain package identity. But apps *packaged with external location* also has package identity. For more info about these terms, see Advantages and disadvantages of packaging your app.

Only packaged apps (including apps packaged with external location) have package identity at runtime. If your app has package identity, then you can use the following features in your app.

Notifications

The Windows App SDK notifications APIs require your app to have package identity.

Integrate with package extensions

If your app needs to integrate with the system (for example, establish firewall rules), then describe those things in the package manifest of your app, and the system will do the rest. For most of these tasks, you won't have to write any code at all. With a bit of XML in the manifest, you can do things such as: start a process when the user logs on; integrate your app into File Explorer; and add your app a list of print targets that appear in other apps.

For more info, see Integrate your desktop app with package extensions.

Get activation info for packaged apps

Starting in Windows 10, version 1809, packaged apps can retrieve certain kinds of activation info during startup. For example, you can get info related to app activation from opening a file, from clicking an interactive toast, or from using a protocol.

For more info, see Get activation info for packaged apps.

Extend with UWP components

Some Windows experiences (for example, a touch-enabled UI page) must run inside of an AppContainer. In general, you should first determine whether you can add your experience by enhancing your existing desktop app with Windows Runtime APIs. If you have to use a UWP component to achieve the experience, then you can add a UWP project to your solution, and use app services to communicate between your desktop app and the UWP component.

For more information, see Extend your desktop app with UWP components.

Distribute

If you package your app in an MSIX package, then it's very easy to distribute it by publishing it the Microsoft Store, or by sideloading it onto systems.

For more info, see Distribute your packaged desktop app.

Integrate your desktop app with Windows by using packaging extensions

Article • 05/07/2024

If your desktop app is packaged (has package identity at runtime), then you can use extensions to integrate your app with Windows by using predefined extensions in the package manifest. Also see Features that require package identity.

For example, use an extension to create a firewall exception; make your app the default application for a file type; or point Start tiles to your app. To use an extension, just add some XML to your app's package manifest file. No code is required.

This topic describes those extensions and the tasks that you can perform by using them.

> **Note**
>
> The features described in this topic require that your app is packaged (has package identity at runtime). That includes packaged apps (see Create a new project for a packaged WinUI 3 desktop app) and packaged apps with external location (see Grant package identity by packaging with external location). Also see Features that require package identity.

Transition users to your app

Help users transition to your packaged app.

- Redirect your existing desktop app to your packaged app
- Point existing Start tiles and taskbar buttons to your packaged app
- Make your packaged app open files instead of your desktop app
- Associate your packaged app with a set of file types
- Add options to the context menus of files that have a certain file type
- Open certain types of files directly by using a URL

Redirect your existing desktop app to your packaged app

When users start your existing unpackaged desktop app, you can configure your packaged app to be opened instead.

> **Note**

This feature is supported in Windows Insider Preview Build 21313 and later versions.

To enable this behavior:

1. Add registry entries to redirect your unpackaged desktop app executable to your packaged app.
2. Register your packaged app to be launched when your unpackaged desktop app executable is launched.

Add registry entries to redirect your unpackaged desktop app executable

1. In the registry, create a subkey with the name of your desktop app executable file under the **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options** key.
2. Under this subkey, add the following values:

    - **AppExecutionAliasRedirect** (DWORD): If set to 1, the system will check for an AppExecutionAlias package extension with the same name as the executable. If the **AppExecutionAlias** extension is enabled, the packaged app will be activated using that value.
    - **AppExecutionAliasRedirectPackages** (REG_SZ): The system will redirect only to the listed packages. Packages are listed by their package family name, separated by semicolons. If the special value * is used, the system will redirect to an **AppExecutionAlias** from any package.

For example:

```ini
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\contosoapp.exe
    AppExecutionAliasRedirect = 1
    AppExecutionAliasRedirectPackages = "Microsoft.WindowsNotepad_8weky8webbe"
```

Register your packaged app to be launched

In your package manifest, add an AppExecutionAlias extension that registers the name of your unpackaged desktop app executable. For example:

XML

```
<Package
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"
  IgnorableNamespaces="uap3">
  <Applications>
    <Application>
      <Extensions>
        <uap3:Extension Category="windows.appExecutionAlias" EntryPoint="Win
dows.FullTrustApplication">
          <uap3:AppExecutionAlias>
            <desktop:ExecutionAlias Alias="contosoapp.exe" />
          </uap3:AppExecutionAlias>
        </uap3:Extension>
      </Extensions>
    </Application>
  </Applications>
</Package>
```

Disable the redirection

Users can turn off the redirection and launch your unpackaged app executable via these options:

- They can uninstall the packaged version of your app.
- The user can disable the **AppExecutionAlias** entry for your packaged app in the **App execution aliases** page in **Settings**.

XML namespaces

- `http://schemas.microsoft.com/appx/manifest/uap/windows10/3`
- `http://schemas.microsoft.com/appx/manifest/desktop/windows10`

Elements and attributes of this extension

XML

```
<uap3:Extension
    Category="windows.appExecutionAlias"
    EntryPoint="Windows.FullTrustApplication">
    <uap3:AppExecutionAlias>
        <desktop:ExecutionAlias Alias="[AliasName]" />
    </uap3:AppExecutionAlias>
</uap3:Extension>
```

Expand table

Name	Description
Category	Always `windows.appExecutionAlias`.
Executable	The relative path to the executable to start when the alias is invoked.
Alias	The short name for your app. It must always end with the ".exe" extension.

Point existing Start tiles and taskbar buttons to your packaged app

Your users might have pinned your desktop application to the taskbar or the Start menu. You can point those shortcuts to your new packaged app.

XML namespace

`http://schemas.microsoft.com/appx/manifest/foundation/windows10/restrictedcapabilities/3`

Elements and attributes of this extension

XML

```xml
<Extension Category="windows.desktopAppMigration">
    <DesktopAppMigration>
        <DesktopApp AumId="[your_app_aumid]" />
        <DesktopApp ShortcutPath="[path]" />
    </DesktopAppMigration>
</Extension>
```

Find the complete schema reference here.

Expand table

Name	Description
Category	Always `windows.desktopAppMigration`.
AumID	The Application User Model ID of your packaged app.
ShortcutPath	The path to .lnk files that start the desktop version of your app.

Example

Make your packaged application open files instead of your desktop app

You can make sure that users open your new packaged application by default for specific types of files instead of opening the desktop version of your app.

To do that, you'll specify the programmatic identifier (ProgID) of each application from which you want to inherit file associations.

XML namespaces

- `http://schemas.microsoft.com/appx/manifest/uap/windows10/3`

- `http://schemas.microsoft.com/appx/manifest/foundation/windows10/restrictedcapabilities/3`

Elements and attributes of this extension

XML

```
<Extension Category="windows.fileTypeAssociation">
    <FileTypeAssociation Name="[Name]">
         <MigrationProgIds>
            <MigrationProgId>"[ProgID]"</MigrationProgId>
        </MigrationProgIds>
    </FileTypeAssociation>
</Extension>
```

Find the complete schema reference here.

Expand table

Name	Description
Category	Always `windows.fileTypeAssociation`.
Name	The name of the file type association. You can use this name to organize and group file types. The name must be all lower case characters with no spaces.
MigrationProgId	The programmatic identifier (ProgID) that describes the application, component, and version of the desktop application from which you want to inherit file associations.

Example

XML

```
<Package
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"

xmlns:rescap3="http://schemas.microsoft.com/appx/manifest/foundation/windows10/restrictedcapabilities/3"
  IgnorableNamespaces="uap3, rescap3">
  <Applications>
    <Application>
      <Extensions>
        <uap:Extension Category="windows.fileTypeAssociation">
          <uap3:FileTypeAssociation Name="myfiletypes">
            <rescap3:MigrationProgIds>
              <rescap3:MigrationProgId>Foo.Bar.1</rescap3:MigrationProgId>
              <rescap3:MigrationProgId>Foo.Bar.2</rescap3:MigrationProgId>
```

```
            </rescap3:MigrationProgIds>
          </uap3:FileTypeAssociation>
        </uap:Extension>
      </Extensions>
    </Application>
  </Applications>
</Package>
```

Add options to the context menus of files that have a certain file type

This extension enables you to add options to the context menu that displays when users right-click a file in File Explorer.These options give users other ways to interact with your file such as print, edit, or preview the file. For more information about using this extension, see Integrate a packaged desktop app with File Explorer.

Expand table

Name	Description
Category	Always `windows.fileTypeAssociation`.
Name	The name of the file type association. You can use this name to organize and group file types. The name must be all lower case characters with no spaces.
Verb	The name that appears in the File Explorer context menu. This string is localizable that uses `ms-resource`.
Id	The unique Id of the verb. If your application is a UWP app, this is passed to your app as part of its activation event args so it can handle the user's selection appropriately. If your application is a full-trust packaged app, it receives parameters instead (see the next bullet).
Parameters	The list of argument parameters and values associated with the verb. If your application is a full-trust packaged app, these parameters are passed to the application as event args when the application is activated. You can customize the behavior of your application based on different activation verbs. If a variable can contain a file path, wrap the parameter value in quotes. That will avoid any issues that happen in cases where the path includes spaces. If your application is a UWP app, you can't pass parameters. The app receives the Id instead (see the previous bullet).
Extended	Specifies that the verb appears only if the user shows the context menu by holding the **Shift** key before right-clicking the file. This attribute is optional and defaults to a

Name	Description
	value of **False** (for example, always show the verb) if not listed. You specify this behavior individually for each verb (except for "Open," which is always **False**).

Example

XML

```
<Package
  xmlns:uap="http://schemas.microsoft.com/appx/manifest/uap/windows10"

Perform setup tasks

- Create firewall exception for your app
- Place your DLL files into any folder of the package

Create firewall exception for your app

If your application requires communication through a port, you can add your application to the list of firewall exceptions.

> ⓘ Note
>
> To use the "windows.firewallRules" extension category (see below), your package needs the **Full Trust Permission Level** restricted capability. See Restricted capability list.

XML namespace

`http://schemas.microsoft.com/appx/manifest/desktop/windows10/2`

Elements and attributes of this extension

XML

```
<Extension Category="windows.firewallRules">
  <FirewallRules Executable="[executable file name]">
    <Rule
      Direction="[Direction]"
      IPProtocol="[Protocol]"
      LocalPortMin="[LocalPortMin]"
      LocalPortMax="LocalPortMax"
      RemotePortMin="RemotePortMin"
      RemotePortMax="RemotePortMax"
      Profile="[Profile]"/>
  </FirewallRules>
</Extension>
```

Find the complete schema reference here.

Expand table

Name	Description
Category	Always `windows.firewallRules`
Executable	The name of the executable file that you want to add to the list of firewall exceptions
Direction	Indicates whether the rule is an inbound or outbound rule
IPProtocol	The communication protocol
LocalPortMin	The lower port number in a range of local port numbers.
LocalPortMax	The highest port number of a range of local port numbers.
RemotePortMax	The lower port number in a range of remote port numbers.
RemotePortMax	The highest port number of a range of remote port numbers.
Profile	The network type

Example

XML

```
<Package

          <desktop2:Rule Direction="in" IPProtocol="TCP" Profile="all"/>
          <desktop2:Rule Direction="in" IPProtocol="UDP" LocalPortMin="1337"
LocalPortMax="1338" Profile="domain"/>
          <desktop2:Rule Direction="in" IPProtocol="UDP" LocalPortMin="1337"
LocalPortMax="1338" Profile="public"/>
          <desktop2:Rule Direction="out" IPProtocol="UDP"
LocalPortMin="1339" LocalPortMax="1340" RemotePortMin="15"
                         RemotePortMax="19" Profile="domainAndPrivate"/>
          <desktop2:Rule Direction="out" IPProtocol="GRE"
Profile="private"/>
      </desktop2:FirewallRules>
  </desktop2:Extension>
```

```
</Extensions>
</Package>
```

Place your DLL files into any folder of the package

Use the uap6:LoaderSearchPathOverride extension to declare up to five folder paths in the app package, relative to the app package root path, to be used in the loader search path for the app's processes.

The DLL search order for Windows apps includes packages in the package dependency graph if the packages have execution rights. By default, this includes main, optional and framework packages, although this can be overwritten by the uap6:AllowExecution element in the package manifest.

A package that is included in the DLL search order will, by default, include its *effective path*. For more information about effective paths, see the EffectivePath property (WinRT) and the PackagePathType enumeration (Win32).

If a package specifies uap6:LoaderSearchPathOverride, then this information is used instead of the package's effective path.

Each package can contain only one uap6:LoaderSearchPathOverride extension. That means that you can add one of them to your main package, and then add one to each of your optional packages, and related sets.

XML namespace

`http://schemas.microsoft.com/appx/manifest/uap/windows10/6`

Elements and attributes of this extension

Declare this extension at the package-level of your app manifest.

XML

```
<Extension Category="windows.loaderSearchPathOverride">
  <LoaderSearchPathOverride>
    <LoaderSearchPathEntry FolderPath="[path]"/>
  </LoaderSearchPathOverride>
</Extension>
```

Expand table

Name	Description
Category	Always `windows.loaderSearchPathOverride`.
FolderPath	The path of the folder that contains your DLL files. Specify a path that is relative to the root folder of the package. You can specify up to five paths in one extension. If you want the system to search for files in the root folder of the package, use an empty string for one of these paths. Don't include duplicate paths, and make sure that your paths don't contain leading and trailing slashes or backslashes. The system won't search subfolders, so make sure to explicitly list each folder that contains DLL files that you want the system to load.

Example

XML

```
<Package
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/6"
  IgnorableNamespaces="uap6">
  ...
    <Extensions>
      <uap6:Extension Category="windows.loaderSearchPathOverride">
        <uap6:LoaderSearchPathOverride>
          <uap6:LoaderSearchPathEntry FolderPath=""/>
          <uap6:LoaderSearchPathEntry FolderPath="folder1/subfolder1"/>
          <uap6:LoaderSearchPathEntry FolderPath="folder2/subfolder2"/>
        </uap6:LoaderSearchPathOverride>
      </uap6:Extension>
    </Extensions>
...
</Package>
```

Integrate with File Explorer

Help users organize your files and interact with them in familiar ways.

- Define how your application behaves when users select and open multiple files at the same time
- Show file contents in a thumbnail image within File Explorer
- Show file contents in a Preview pane of File Explorer
- Enable users to group files by using the Kind column in File Explorer
- Make file properties available to search, index, property dialogs, and the details pane

- Specify a context menu handler for a file type
- Make files from your cloud service appear in File Explorer

Define how your application behaves when users select and open multiple files at the same time

Specify how your application behaves when a user opens multiple files simultaneously.

XML namespaces

- `http://schemas.microsoft.com/appx/manifest/uap/windows10`
- `http://schemas.microsoft.com/appx/manifest/uap/windows10/2`
- `http://schemas.microsoft.com/appx/manifest/uap/windows10/3`

Elements and attributes of this extension

Expand table

Name	Description
Category	Always `windows.fileTypeAssociation`.
Name	The name of the file type association. You can use this name to organize and group file types. The name must be all lower case characters with no spaces.
MultiSelectModel	See below
FileType	The relevant file extensions.

MultiSelectModel

packaged desktop apps have the same three options as regular desktop apps.

- `Player`: Your application is activated one time. All of the selected files are passed to your application as argument parameters.
- `Single`: Your application is activated one time for the first selected file. Other files are ignored.
- `Document`: A new, separate instance of your application is activated for each selected file.

You can set different preferences for different file types and actions. For example, you may wish to open *Documents* in *Document* mode and *Images* in *Player* mode.

Example

XML

```
<Package
  xmlns:uap="http://schemas.microsoft.com/appx/manifest/uap/windows10"
  xmlns:uap2="http://schemas.microsoft.com/appx/manifest/uap/windows10/2"
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"
  IgnorableNamespaces="uap, uap2, uap3">
  <Applications>
    <Application>
      <Extensions>
        <uap:Extension Category="windows.fileTypeAssociation">
          <uap3:FileTypeAssociation Name="myfiletypes"
MultiSelectModel="Document">
            <uap2:SupportedVerbs>
              <uap3:Verb Id="Edit"
MultiSelectModel="Player">Edit</uap3:Verb>
              <uap3:Verb Id="Preview"
MultiSelectModel="Document">Preview</uap3:Verb>
            </uap2:SupportedVerbs>
            <uap:SupportedFileTypes>
              <uap:FileType>.txt</uap:FileType>
            </uap:SupportedFileTypes>
        </uap:Extension>
      </Extensions>
    </Application>
  </Applications>
</Package>
```

If the user opens 15 or fewer files, the default choice for the **MultiSelectModel** attribute is *Player*. Otherwise, the default is *Document*. UWP apps are always started as *Player*.

Show file contents in a thumbnail image within File Explorer

Enable users to view a thumbnail image of the file's contents when the icon of the file appears in the medium, large, or extra large size.

Enable users to group files by using the Kind column in File Explorer

You can associate one or more predefined values for your file types with the **Kind** field.

In File Explorer, users can group those files by using that field. System components also use this field for various purposes such as indexing.

For more information about the **Kind** field and the values that you can use for this field, see Using Kind Names.

Instructions

To register your context menu handler, follow these instructions.

1. In your desktop application, implement a context menu handler by implementing the IExplorerCommand or IExplorerCommandState interface. For a sample, see the ExplorerCommandVerb code sample. Make sure that you define a class GUID for each of your implementation objects. For example, the following code defines a class ID for an implementation of IExplorerCommand.

   C++

```
class __declspec(uuid("00001111-aaaa-2222-bbbb-3333cccc4444"))
CExplorerCommandVerb;
```

2. In your package manifest, specify a com:ComServer application extension that registers a COM surrogate server with the class ID of your context menu handler implementation.

```
XML

<com:Extension Category="windows.comServer">
    <com:ComServer>
        <com:SurrogateServer AppId="00001111-aaaa-2222-bbbb-
3333cccc4444" DisplayName="ContosoHandler">
            <com:Class Id="00001111-aaaa-2222-bbbb-3333cccc4444"
Path="ExplorerCommandVerb.dll" ThreadingModel="STA"/>
        </com:SurrogateServer>
    </com:ComServer>
</com:Extension>
```

3. In your package manifest, specify a desktop4:FileExplorerContextMenus application extension that registers your context menu handler implementation.

```
XML

<desktop4:Extension Category="windows.fileExplorerContextMenus">
    <desktop4:FileExplorerContextMenus>
        <desktop4:ItemType Type=".rar">
            <desktop4:Verb Id="Command1" Clsid="00001111-aaaa-2222-
bbbb-3333cccc4444" />
        </desktop4:ItemType>
    </desktop4:FileExplorerContextMenus>
</desktop4:Extension>
```

Example

```
XML

<Package
  xmlns="http://schemas.microsoft.com/appx/manifest/foundation/windows10"

xmlns:desktop4="http://schemas.microsoft.com/appx/manifest/desktop/windows10
/4"
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"
  IgnorableNamespaces="desktop4">
  <Applications>
    <Application>
      <Extensions>
```

```
        <com:Extension Category="windows.comServer">
          <com:ComServer>
            <com:SurrogateServer AppId="00001111-aaaa-2222-bbbb-
3333cccc4444" DisplayName="ContosoHandler">
              <com:Class Id="00001111-aaaa-2222-bbbb-3333cccc4444"
Path="ExplorerCommandVerb.dll" ThreadingModel="STA"/>
            </com:SurrogateServer>
          </com:ComServer>
        </com:Extension>
        <desktop4:Extension Category="windows.fileExplorerContextMenus">
          <desktop4:FileExplorerContextMenus>
            <desktop4:ItemType Type=".contoso">
              <desktop4:Verb Id="Command1" Clsid="00001111-aaaa-2222-bbbb-
3333cccc4444" />
            </desktop4:ItemType>
          </desktop4:FileExplorerContextMenus>
        </desktop4:Extension>
      </Extensions>
    </Application>
  </Applications>
</Package>
```

Make files from your cloud service appear in File Explorer

Register the handlers that you implement in your application. You can also add context menu options that appear when you users right-click your cloud-based files in File Explorer.

XML namespace

- `http://schemas.microsoft.com/appx/manifest/desktop/windows10`

Elements and attributes of this extension

XML

```
<Extension Category="windows.cloudfiles" >
    <CloudFiles IconResource="[Icon]">
        <CustomStateHandler Clsid ="[Clsid]"/>
        <ThumbnailProviderHandler Clsid ="[Clsid]"/>
        <ExtendedPropertyhandler Clsid ="[Clsid]"/>
        <CloudFilesContextMenus>
            <Verb Id ="Command3" Clsid= "[GUID]">[Verb Label]</Verb>
        </CloudFilesContextMenus>
    </CloudFiles>
</Extension>
```

Expand table

Name	Description
Category	Always `windows.cloudfiles`.
iconResource	The icon that represents your cloud file provider service. This icon appears in the Navigation pane of File Explorer. Users choose this icon to show files from your cloud service.
CustomStateHandler Clsid	The class ID of the application that implements the CustomStateHandler. The system uses this Class ID to request custom states and columns for cloud files.
ThumbnailProviderHandler Clsid	The class ID of the application that implements the ThumbnailProviderHandler. The system uses this Class ID to request thumbnail images for cloud files.
ExtendedPropertyHandler Clsid	The class ID of the application that implements the ExtendedPropertyHandler. The system uses this Class ID to request extended properties for a cloud file.
Verb	The name that appears in the File Explorer context menu for files provided by your cloud service.
Id	The unique ID of the verb.

Example

XML

```
<Package

xmlns:desktop="http://schemas.microsoft.com/appx/manifest/desktop/windows10"
    IgnorableNamespaces="desktop">
  <Applications>
    <Application>
      <Extensions>
        <Extension Category="windows.cloudfiles" >
            <CloudFiles IconResource="images\Wide310x150Logo.png">
                <CustomStateHandler Clsid ="20000000-0000-0000-0000-
000000000001"/>
                <ThumbnailProviderHandler Clsid ="20000000-0000-0000-0000-
000000000001"/>
                <ExtendedPropertyhandler Clsid ="20000000-0000-0000-0000-
000000000001"/>
                <desktop:CloudFilesContextMenus>
                    <desktop:Verb Id ="keep" Clsid=
                       "20000000-0000-0000-0000-000000000001">
                       Always keep on this device</desktop:Verb>
                </desktop:CloudFilesContextMenus>
```

```
            </CloudFiles>
          </Extension>
        </Extensions>
      </Application>
    </Applications>
</Package>
```

Start your application in different ways

- Start your application by using a protocol
- Start your application by using an alias
- Start an executable file when users log into Windows
- Enable users to start your application when they connect a device to their PC
- Restart automatically after receiving an update from the Microsoft Store

Start your application by using a protocol

Protocol associations can enable other programs and system components to interoperate with your packaged app. When your packaged application is started by using a protocol, you can specify specific parameters to pass to its activation event arguments so it can behave accordingly. Parameters are supported only for packaged, full-trust apps. UWP apps can't use parameters.

XML namespace

`http://schemas.microsoft.com/appx/manifest/uap/windows10/3`

Elements and attributes of this extension

XML

```
<Extension
    Category="windows.protocol">
  <Protocol
      Name="[Protocol name]"
      Parameters="[Parameters]" />
</Extension>
```

Find the complete schema reference here.

Expand table

Name	Description
Category	Always `windows.protocol`.
Name	The name of the protocol.
Parameters	The list of parameters and values to pass to your application as event arguments when the application is activated. If a variable can contain a file path, wrap the parameter value in quotes. That will avoid any issues that happen in cases where the path includes spaces.

Example

XML

```
<Package
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"

xmlns:desktop="http://schemas.microsoft.com/appx/manifest/desktop/windows10"
  IgnorableNamespaces="uap3, desktop">
  <Applications>
    <Application>
      <Extensions>
        <uap3:Extension
          Category="windows.protocol">
          <uap3:Protocol
            Name="myapp-cmd"
            Parameters="/p &amp;quot;%1&amp;quot;" />
        </uap3:Extension>
      </Extensions>
    </Application>
  </Applications>
</Package>
```

Start your application by using an alias

Users and other processes can use an alias to start your application without having to specify the full path to your app. You can specify that alias name.

XML namespaces

- `http://schemas.microsoft.com/appx/manifest/uap/windows10/3`
- `http://schemas.microsoft.com/appx/manifest/desktop/windows10`

Elements and attributes of this extension

XML

```xml
<uap3:Extension
    Category="windows.appExecutionAlias"
    Executable="[ExecutableName]"
    EntryPoint="Windows.FullTrustApplication">
    <uap3:AppExecutionAlias>
        <desktop:ExecutionAlias Alias="[AliasName]" />
    </uap3:AppExecutionAlias>
</uap3:Extension>
```

Expand table

Name	Description
Category	Always `windows.appExecutionAlias`.
Executable	The relative path to the executable to start when the alias is invoked.
Alias	The short name for your app. It must always end with the ".exe" extension. You can only specify a single app execution alias for each application in the package. If multiple apps register for the same alias, the system will invoke the last one that was registered, so make sure to choose a unique alias other apps are unlikely to override.

Example

XML

```xml
<Package
  xmlns:uap3="http://schemas.microsoft.com/appx/manifest/uap/windows10/3"
  IgnorableNamespaces="uap3">
  <Applications>
    <Application>
      <Extensions>
         <uap3:Extension
                Category="windows.appExecutionAlias"
                Executable="exes\launcher.exe"
                EntryPoint="Windows.FullTrustApplication">
            <uap3:AppExecutionAlias>
                <desktop:ExecutionAlias Alias="Contoso.exe" />
            </uap3:AppExecutionAlias>
        </uap3:Extension>
      </Extensions>
    </Application>
  </Applications>
</Package>
```

Find the complete schema reference here.

Start an executable file when users log into Windows

Startup tasks allow your application to run an executable automatically whenever a user logs on.

> **Note**
>
> The user has to start your application at least one time to register this startup task.

Your application can declare multiple startup tasks. Each task starts independently. All startup tasks will appear in Task Manager under the **Startup** tab with the name that you specify in your app's manifest and your app's icon. Task Manager will automatically analyze the startup impact of your tasks.

Users can manually disable your app's startup task by using Task Manager. If a user disables a task, you can't programmatically re-enable it.

XML namespace

`http://schemas.microsoft.com/appx/manifest/desktop/windows10`

Elements and attributes of this extension

XML

```xml
<Extension
    Category="windows.startupTask"
    Executable="[ExecutableName]"
    EntryPoint="Windows.FullTrustApplication">
  <StartupTask
      TaskId="[TaskID]"
      Enabled="true"
      DisplayName="[DisplayName]" />
</Extension>
```

Expand table

Name	Description
Category	Always `windows.startupTask`.
Executable	The relative path to the executable file to start.

Name	Description
TaskId	A unique identifier for your task. Using this identifier, your application can call the APIs in the Windows.ApplicationModel.StartupTask class to programmatically enable or disable a startup task.
Enabled	Indicates whether the task first starts enabled or disabled. Enabled tasks will run the next time the user logs on (unless the user disables it).
DisplayName	The name of the task that appears in Task Manager. You can localize this string by using `ms-resource`.

Example

XML

```
<Package

xmlns:desktop="http://schemas.microsoft.com/appx/manifest/desktop/windows10"
  IgnorableNamespaces="desktop">
  <Applications>
    <Application>
      <Extensions>
        <desktop:Extension
          Category="windows.startupTask"
          Executable="bin\MyStartupTask.exe"
          EntryPoint="Windows.FullTrustApplication">
        <desktop:StartupTask
          TaskId="MyStartupTask"
          Enabled="true"
          DisplayName="My App Service" />
        </desktop:Extension>
      </Extensions>
    </Application>
  </Applications>
 </Package>
```

Enable users to start your application when they connect a device to their PC

AutoPlay can present your application as an option when a user connects a device to their PC.

XML namespace

`http://schemas.microsoft.com/appx/manifest/desktop/windows10/3`

Elements and attributes of this extension

XML

```
<Extension Category="windows.autoPlayHandler">
  <AutoPlayHandler>
    <InvokeAction ActionDisplayName="[action string]" ProviderDisplayName="
[name of your app/service]">
      <Content ContentEvent="[Content event]" Verb="[any string]"
DropTargetHandler="[Clsid]" />
      <Content ContentEvent="[Content event]" Verb="[any string]"
Parameters="[Initialization parameter]"/>
      <Device DeviceEvent="[Device event]" HWEventHandler="[Clsid]"
InitCmdLine="[Initialization parameter]"/>
    </InvokeAction>
  </AutoPlayHandler>
```

Expand table

Name	Description
Category	Always `windows.autoPlayHandler`.
ActionDisplayName	A string that represents the action that users can take with a device that they connect to a PC (For example: "Import files", or "Play video").
ProviderDisplayName	A string that represents your application or service (For example: "Contoso video player").
ContentEvent	The name of a content event that causes users to be prompted with your `ActionDisplayName` and `ProviderDisplayName`. A content event is raised when a volume device such as a camera memory card, thumb drive, or DVD is inserted into the PC. You can find the full list of those events here.
Verb	The Verb setting identifies a value that is passed to your application for the selected option. You can specify multiple launch actions for an AutoPlay event and use the Verb setting to determine which option a user has selected for your app. You can tell which option the user selected by checking the verb property of the startup event arguments passed to your app. You can use any value for the Verb setting except, open, which is reserved.
DropTargetHandler	The class ID of the application that implements the IDropTarget interface. Files from the removable media are passed to the Drop method of your IDropTarget implementation.
Parameters	You don't have to implement the IDropTarget interface for all content events. For any of the content events, you could provide command line parameters instead of implementing the IDropTarget interface. For those events, AutoPlay will start your application by using those command line

Name	Description
	parameters. You can parse those parameters in your app's initialization code to determine if it was started by AutoPlay and then provide your custom implementation.
DeviceEvent	The name of a device event that causes users to be prompted with your `ActionDisplayName` and `ProviderDisplayName`. A device event is raised when a device is connected to the PC. Device events begin with the string `WPD` and you can find them listed here.
HWEventHandler	The Class ID of the application that implements the IHWEventHandler interface.
InitCmdLine	The string parameter that you want to pass into the Initialize method of the IHWEventHandler interface.

Example

XML

```
<Package

xmlns:desktop3="http://schemas.microsoft.com/appx/manifest/desktop/windows10
/3"
  IgnorableNamespaces="desktop3">
  <Applications>
    <Application>
      <Extensions>
        <desktop3:Extension Category="windows.autoPlayHandler">
          <desktop3:AutoPlayHandler>
            <desktop3:InvokeAction ActionDisplayName="Import my files"
ProviderDisplayName="ms-resource:AutoPlayDisplayName">
              <desktop3:Content ContentEvent="ShowPicturesOnArrival"
Verb="show" DropTargetHandler="CD041BAE-0DEA-4472-9B7B-C98043D26EA8"/>
              <desktop3:Content ContentEvent="PlayVideoFilesOnArrival"
Verb="play" Parameters="%1" />
              <desktop3:Device DeviceEvent="WPD\ImageSource"
HWEventHandler="CD041BAE-0DEA-4472-9B7B-C98043D26EA8"
InitCmdLine="/autoplay"/>
            </desktop3:InvokeAction>
          </desktop3:AutoPlayHandler>
      </Extensions>
    </Application>
  </Applications>
</Package>
```

Restart automatically after receiving an update from the Microsoft Store

If your application is open when users install an update to it, the application closes.

If you want that application to restart after the update completes, call the RegisterApplicationRestart function in every process that you want to restart.

Each active window in your application receives a WM_QUERYENDSESSION message. At this point, your application can call the RegisterApplicationRestart function again to update the command line if necessary.

When each active window in your application receives the WM_ENDSESSION message, your application should save data and shut down.

> **Note**
>
> Your active windows also receive the **WM_CLOSE** message in case the application doesn't handle the **WM_ENDSESSION** message.

At this point, your application has 30 seconds to close it's own processes or the platform terminates them forcefully.

After the update is complete, your application restarts.

Work with other applications

Integrate with other apps, start other processes or share information.

- Make your application appear as the print target in applications that support printing
- Share fonts with other Windows applications
- Start a Win32 process from a Universal Windows Platform (UWP) app

Make your application appear as the print target in applications that support printing

When users want to print data from another application such as Notepad, you can make your application appear as a print target in the app's list of available print targets.

You'll have to modify your application so that it receives print data in XML Paper Specification (XPS) format.

XML namespaces

                  <desktop:ParameterGroup GroupId="SyncGroup"
Parameters="/Sync"/>
                  <desktop:ParameterGroup GroupId="OtherGroup"
Parameters="/Other"/>
              </desktop:FullTrustProcess>
           </desktop:Extension>
      </Extensions>
    </Application>
  </Applications>
</Package>
```

This extension might be useful if you want to create a Universal Windows Platform User interface that runs on all devices, but you want components of your Win32 application to continue running in full-trust.

Just create a Windows app package for your Win32 app. Then, add this extension to the package file of your UWP app. This extensions indicates that you want to start an executable file in the Windows app package. If you want to communicate between your UWP app and your Win32 app, you can set up one or more app services to do that. You can read more about this scenario here.

Integrate a packaged desktop app with File Explorer

Article • 05/03/2022

Some Windows apps define File Explorer extensions that add context menu entries that enable customers to perform options related to the app. Older Windows app deployment technologies such MSI and ClickOnce define File Explorer extensions through the registry. The registry has a series of hives which control File Explorer extensions and other types of Shell extensions. These installers typically create a series of registry keys to configure the various items to include in the context menu.

If you package your Windows app using MSIX, the registry is virtualized, and therefore your app can't register File Explorer extensions via the registry. Instead, you must define your File Explorer extensions via package extensions, which you define in the package manifest. This article describes several ways to do this.

You can find the complete sample code used in this article on GitHub.

Add a context menu entry that supports startup parameters

One of the simplest ways to integrate with File Explorer is to define a package extension that adds your app to the list of available apps in the context menu when a user right-clicks a specific file type in File Explorer. If the user opens your app, your extension can pass parameters to your app.

This scenario has several limitations:

- It works only in combination with the file type association feature. You can display additional options in the context menu only for file types which are associated with the main app (for example, your app supports opening a file by double-clicking it in File Explorer).
- The options in the context menu will be displayed only if your app is set as default for that file type.
- The only supported action is to launch the main executable of the app (that is, the same executable that is connected to the Start menu entry). However, every action can specify different parameters, which you can use when the apps start to understand which action triggered the execution and perform different tasks.

Despite these limitations, this approach is sufficient for many scenarios. For example, if you're building an image editor, you can easily add an entry in the context menu to resize an image, which will launch the image editor directly with a wizard to start the resizing process.

Implement the context menu entry

To support this scenario, add an Extension element with the category `windows.fileTypeAssociation` to your package manifest. This element must be added as a child of the Extensions element under the Application element.

The following example demonstrates a registration for an app that enables context menus for files with the `.foo` extension. This example specifies the `.foo` extension because this is a fake extension that is typically not registered to other apps on any given computer. If you need to manage a file type which might already be taken (like .txt or .jpg), remember that you won't be able to see the option until your app is set as default for that file type. This example is an excerpt from the Package.appxmanifest file in the related sample on GitHub.

XML

```
<Extensions>
  <uap3:Extension Category="windows.fileTypeAssociation">
    <uap3:FileTypeAssociation Name="foo" Parameters="&quot;%1&quot;">
      <uap:SupportedFileTypes>
        <uap:FileType>.foo</uap:FileType>
      </uap:SupportedFileTypes>
      <uap2:SupportedVerbs>
        <uap3:Verb Id="Resize" Parameters="&quot;%1&quot; /p">Resize
file</uap3:Verb>
      </uap2:SupportedVerbs>
    </uap3:FileTypeAssociation>
  </uap3:Extension>
</Extensions>
```

This example assumes that the following namespaces and aliases are declared in the root `<Package>` element in the manifest.

XML

```
<Package
  xmlns="http://schemas.microsoft.com/appx/manifest/foundation/windows10"
  xmlns:uap="http://schemas.microsoft.com/appx/manifest/uap/windows10"
  xmlns:uap2="http://schemas.microsoft.com/appx/manifest/uap/windows10/2"

  ...
</Package>
```

The FileTypeAssociation element associates your app with the file type(s) you want to support. For more details, see Associate your packaged application with a set of file types. Here are the most important items related to this element.

Attribute or element	Description
`Name` attribute	Matches the name of the extension you want to register minus the dot (in the previous example, `foo`).
`Parameters` attribute	Contains the parameters you want to pass to your application when the user double-clicks a file with such extension. Typically, at least, you pass `%1`, which is a special parameter that contains the path of the selected file. This way, when you double click on a file, the application knows its full path and can load it.
SupportedFileTypes element	Specifies the name(s) of the extension you want to register, including the dot (in this example, `.foo`). You can specify multiple `<FileType>` entries you want to support more file types.

To define the context menu integration, you must also add the SupportedVerbs child element. This element contains one or more Verb elements that define the options that will be listed when a user right-clicks a file with the .foo extension in File Explorer. For more details, see Add options to the context menus of files that have a certain file type. Here are the most important items related to the Verb element.

Attribute or element	Description
`Id` attribute	Specifies the unique identifier for the action.
`Parameters` attribute	Similar to the FileTypeAssociation element, this attribute for the Verb element contains the parameters that are passed to your application when the user clicks the context menu entry. Typically, other than the `%1` special parameter to get the path of the selected file, you pass also one or more parameters to get the context. This enables your app to understand that it was opened from a context menu entry.
Element value	The value of the Verb element contains the label to display in the context menu entry (in this example, **Resize file**).

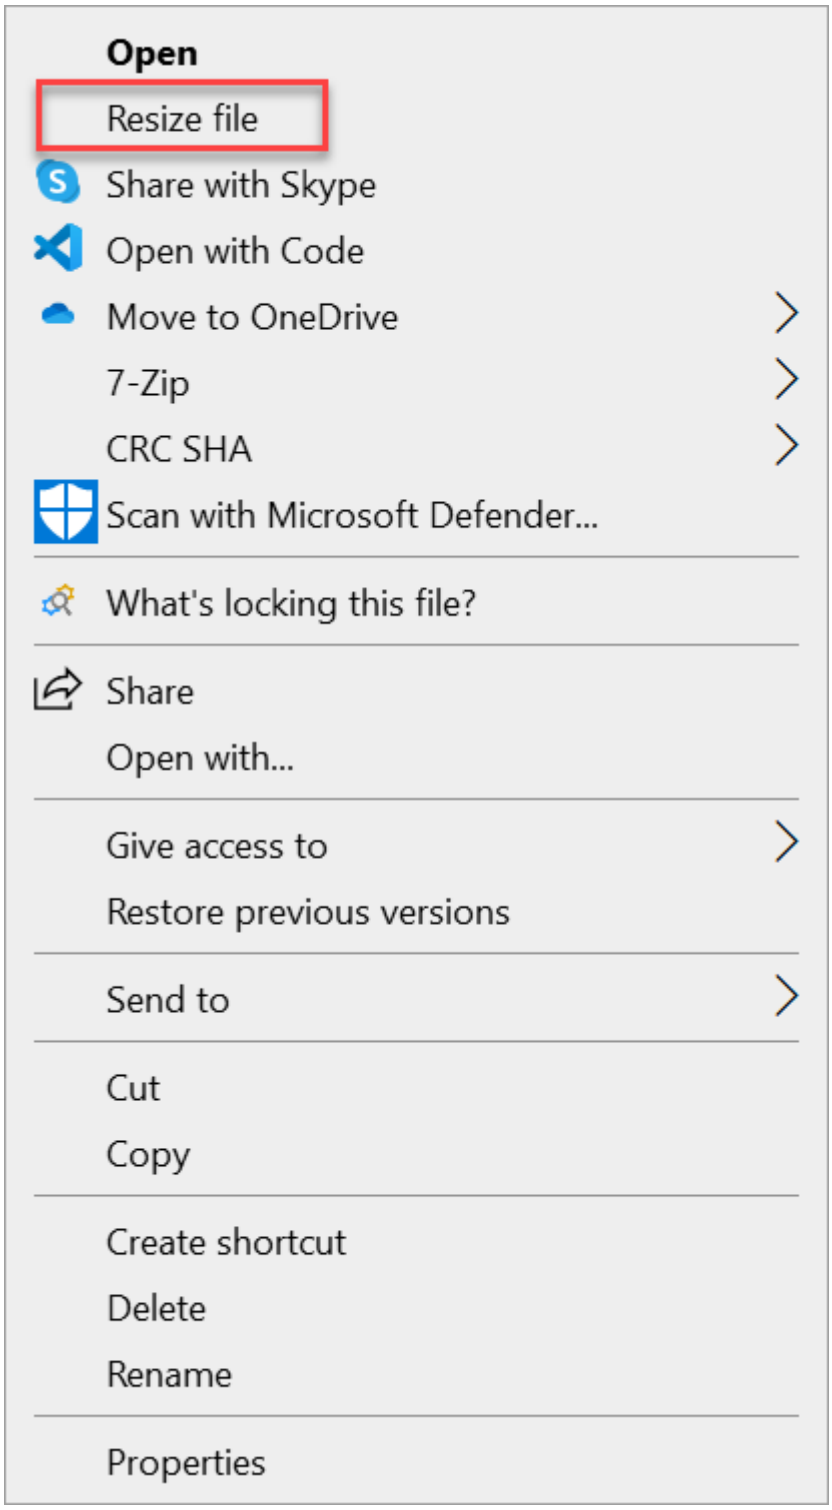
Access the startup parameters in your app code

The way your app receives the parameters depends on the type of app you have created. For example, a WPF app typically processes startup event args in the `OnStartup` method of the `App` class. You can check if there are startup parameters and, based on the outcome, take the most appropriate action (like opening a specific window of the application instead of the main one).

C#

```
public partial class App : Application
{
    protected override void OnStartup(StartupEventArgs e)
    {
        if (e.Args.Contains("Resize"))
        {
            // Open a specific window of the app.
        }
        else
        {
            MainWindow main = new MainWindow();
            main.Show();
        }
    }
}
```

The following screenshot demonstrates the **Resize File** context menu entry created by the previous example.



Support generic files or folders and perform complex tasks

Although using the FileTypeAssociation extension in the package manifest as described in the previous section is sufficient for many scenarios, you may find it limiting. The two biggest challenges are:

- You can handle only file types you are associated with. For example, you can't handle a generic folder.

- You can only launch the app with a series of parameters. You can't perform advanced operations, like launching another executable or performing a task without opening the main app.

To achieve these goals, you must create a Shell extension, which provides more powerful ways to integrate with File Explorer. In this scenario, you create a DLL that contains everything required to manage the file context menu, including the label, icon, state, and tasks to perform. Because this functionality is implemented in a DLL, you can do nearly everything that you can do with a normal app. After you implement the DLL, you must register it via extensions you define in your package manifest.

> **Note**
>
> The process described in this section has one limitation. After the MSIX package that contains the extension is installed on a target computer, File Explorer must be restarted before the Shell extension can be loaded. To accomplish this, the user can restart the computer, or they can restart the **explorer.exe** process using **Task Manager**.

Implement the Shell extension

Shell extensions are based on COM (Component Object Model). Your DLL exposes one or more COM objects that are registered in the system registry. Windows discovers these COM objects and integrates your extension with File Explorer. Because you're integrating your code with the Windows Shell, performance and memory footprint is important. Therefore, these kinds of extensions are typically built with C++.

For sample code that illustrates how to implement Shell extensions, see the ExplorerCommandVerb project in the related sample on GitHub. This project is based on this sample in the Windows desktop samples, and it has several revisions to make the sample more easy to use with the latest versions of Visual Studio.

This project contains a lot of boilerplate code for different tasks, such as dynamic vs static menus and manual registration of the DLL. Most of this code isn't needed if you're packaging your app using MSIX, because the packaging support will take care of these tasks for you. The ExplorerCommandVerb.cpp file contains the implementation of the context menu, and this is the main code file of interest for this walkthrough.

The key function is `CExplorerCommandVerb::Invoke`. This is the function that is invoked when a user clicks on the entry in the context menu. In the sample, to minimize the

impact on the performance, the operation is performed on another thread, so you will actually find the real implementation in `CExplorerCommandVerb::_ThreadProc`.

C++

```
DWORD CExplorerCommandVerb::_ThreadProc()
{
    IShellItemArray* psia;
    HRESULT hr = CoGetInterfaceAndReleaseStream(_pstmShellItemArray,
IID_PPV_ARGS(&psia));
    _pstmShellItemArray = NULL;
    if (SUCCEEDED(hr))
    {
        DWORD count;
        psia->GetCount(&count);

        IShellItem2* psi;
        HRESULT hr = GetItemAt(psia, 0, IID_PPV_ARGS(&psi));
        if (SUCCEEDED(hr))
        {
            PWSTR pszName;
            hr = psi->GetDisplayName(SIGDN_DESKTOPABSOLUTEPARSING,
&pszName);
            if (SUCCEEDED(hr))
            {
                WCHAR szMsg[128];
                StringCchPrintf(szMsg, ARRAYSIZE(szMsg), L"%d item(s), first
item is named %s", count, pszName);

                MessageBox(_hwnd, szMsg, L"ExplorerCommand Sample Verb",
MB_OK);

                CoTaskMemFree(pszName);
            }

            psi->Release();
        }
        psia->Release();
    }

    return 0;
}
```

When a user right-clicks on a file or folder, this function displays a message box with the full path of the selected file or folder. If you want to customize the Shell extension in other ways, you can extend the following functions in the sample:

- You can change the GetTitle function to customize the label of the entry in the context menu.

- You can change the GetIcon function to customize the icon displayed near the entry in the context menu.
- You can change the GetTooltip function to customize the tooltip which is displayed when you hover the entry in the context menu.

Register the Shell extension

Because the Shell extension is based on COM, the implementation DLL must be exposed as a COM server so that Windows can integrate it with File Explorer. Typically, this is done by assigning a unique ID (called CLSID) to the COM server and by registering it in a specific hive of the system registry. In the ExplorerCommandVerb project, the CLSID for the `CExplorerCommandVerb` extension is defined in the Dll.h file.

C++

```
class __declspec(uuid("CC19E147-7757-483C-B27F-3D81BCEB38FE"))
CExplorerCommandVerb;
```

When you package a Shell extension DLL in an MSIX package, you follow a similar approach. However, the GUID must registered inside the package manifest instead of the registry, as explained here.

In your package manifest, start by adding the following namespaces to your **Package** element.

XML

```
<Package

xmlns:desktop="http://schemas.microsoft.com/appx/manifest/desktop/windows10"

xmlns:desktop4="http://schemas.microsoft.com/appx/manifest/desktop/windows10
/4"

xmlns:desktop5="http://schemas.microsoft.com/appx/manifest/desktop/windows10
/5"
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"
  IgnorableNamespaces="desktop desktop4 desktop5 com">

    ...
</Package>
```

To register the CLSID, add a com.Extension element with the category `windows.comServer` to your package manifest. This element must be added as a child of

the Extensions element under the Application element. This example is an excerpt from the Package.appxmanifest file in the related sample on GitHub.

XML

```
<com:Extension Category="windows.comServer">
  <com:ComServer>
    <com:SurrogateServer DisplayName="ContextMenuSample">
      <com:Class Id="CC19E147-7757-483C-B27F-3D81BCEB38FE"
Path="ExplorerCommandVerb.dll" ThreadingModel="STA"/>
    </com:SurrogateServer>
  </com:ComServer>
</com:Extension>
```

There are two critical attributes to configure in the com:Class element.

Attribute	Description
`Id` attribute	This must match with the CLSID of the object you want to register. In this example, this is the CLSID declared in the `Dll.h` file associated to the `CExplorerCommandVerb` class.
`Path` attribute	This must contain the name of the DLL that exposes the COM object. This example includes the DLL in the root of the package, so it can just specify the name of the DLL generated by the `ExplorerCommandVerb` project.

Next, add another extension that registers the file context menu. To do this, add a desktop4:Extension element with the category `windows.fileExplorerContextMenus` to your package manifest. This element must also be added as a child of the Extensions element under the Application element.

XML

```
<desktop4:Extension Category="windows.fileExplorerContextMenus">
  <desktop4:FileExplorerContextMenus>
    <desktop5:ItemType Type="Directory">
      <desktop5:Verb Id="Command1" Clsid="CC19E147-7757-483C-B27F-
3D81BCEB38FE" />
    </desktop5:ItemType>
  </desktop4:FileExplorerContextMenus>
</desktop4:Extension>
```

There are two critical attributes to configure under the desktop4:Extension element.

Attribute or element	Description

Attribute or element	Description
`Type` attribute of desktop5:ItemType	This defines the type of items you want to associate with the context menu. It could be a star (`*`) if you want to display it for all the files; it could be a specific file extension (`.foo`); or it can be available for folders (`Directory`).
`Clsid` attribute of desktop5:Verb	This must match the CLSID that you have previously registered as COM server in the package manifest file.

Configure the DLL in the package

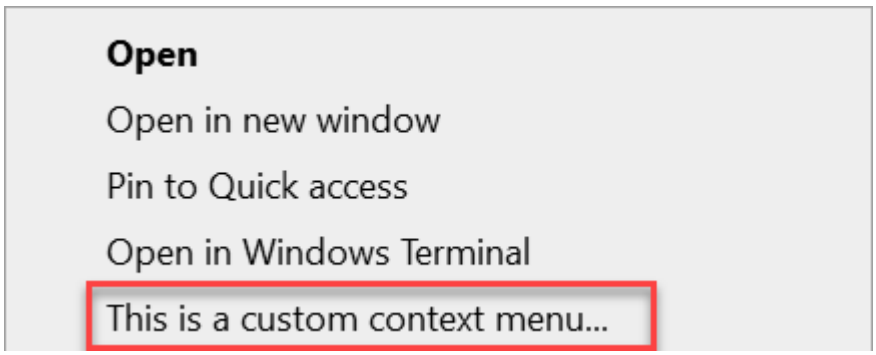
Include the DLL that implements the Shell extension (in this sample, **ExplorerCommandVerb.dll**) in the root of the MSIX package. If you're using the Windows Application Packaging Project, the easiest solution is to copy and paste the DLL into the project and make sure that the **Copy to Output Directory** option for the DLL file properties is set to **Copy if newer**.

To make sure that the package always includes the most recent version of the DLL, you can add a post-build event to the Shell extension project so that, every time you build it, the DLL is copied to the Windows Application Packaging Project.

Restart File Explorer

After you install the Shell extension package, you must restart File Explorer before the Shell extension can be loaded. This is a limitation of Shell extensions that are deployed and registered via MSIX packages.

To test the Shell extension, restart your PC or restart the **explorer.exe** process using **Task Manager**. After you do to that, you should be able to see the entry in the context menu.



If you click on it, the `CExplorerCommandVerb::_ThreadProc` function will be called to display the message box with the path of the selected folder.

Get activation info for packaged apps

Article • 10/24/2022

Starting in Windows 10, version 1809, packaged desktop apps can call the AppInstance.GetActivatedEventArgs method to retrieve certain kinds of app activation info during startup. For example, you can call this method to get info related to app activation from opening a file, clicking an interactive toast, or using a protocol. Starting in Windows 10, version 2004, this feature is also supported in packaged apps with external location (see Grant package identity by packaging with external location).

> **Note**
>
> In addition to retrieving certain types of activation info by using the AppInstance.GetActivatedEventArgs method as described in this article, you can also retrieve activation info for background tasks by defining a COM class. For more info, see Create and register a winmain COM background task.

Code example

The following code example demonstrates how to call the AppInstance.GetActivatedEventArgs method from the **Main** function in a Windows Forms app. For each activation type your app supports, cast the `args` return value to the corresponding event args type. In this code example, the `Handlexxx` methods are assumed to be dedicated activation handler code that you have defined elsewhere.

C#

```
static void Main()
{
    Application.EnableVisualStyles();
    Application.SetCompatibleTextRenderingDefault(false);

    var args = AppInstance.GetActivatedEventArgs();
    switch (args.Kind)
    {
        case ActivationKind.Launch:
            HandleLaunch(args as LaunchActivatedEventArgs);
            break;
        case ActivationKind.ToastNotification:
            HandleToastNotification(args as
ToastNotificationActivatedEventArgs);
            break;
        case ActivationKind.VoiceCommand:
```

```
            HandleVoiceCommand(args as VoiceCommandActivatedEventArgs);
            break;
        case ActivationKind.File:
            HandleFile(args as FileActivatedEventArgs);
            break;
        case ActivationKind.Protocol:
            HandleProtocol(args as ProtocolActivatedEventArgs);
            break;
        case ActivationKind.StartupTask:
            HandleStartupTask(args as StartupTaskActivatedEventArgs);
            break;
        default:
            HandleLaunch(null);
            break;
    }
```

Supported activation types

You can use the AppInstance.GetActivatedEventArgs method to retrieve activation info from the supported set of event args objects listed in the following table. Some of these activation types require the use of a package extension in the package manifest.

ShareTargetActivatedEventArgs activation info is supported only on Windows 10, version 2004, and later. All other activation info types are supported on Windows 10, version 1809, and later.

Expand table

Event args type	Package extension	Related docs
ShareTargetActivatedEventArgs	uap:ShareTarget	Making your desktop application a share target
ProtocolActivatedEventArgs	uap:Protocol	Start your application by using a protocol
ToastNotificationActivatedEventArgs	desktop:ToastNotificationActivation	Toast notifications from desktop apps.
StartupTaskActivatedEventArgs	desktop:StartupTask	Start an executable file when users log into Windows
FileActivatedEventArgs	uap:FileTypeAssociation	Associate your packaged

Event args type	Package extension	Related docs
		application with a set of file types
VoiceCommandActivatedEventArgs	None	Activate a foreground app with voice commands through Cortana
LaunchActivatedEventArgs	None

Extend your desktop app with modern UWP components

Article • 01/03/2023

Some Windows experiences (For example, a touch-enabled UI page) must run inside of an AppContainer. If you want to add such experiences, then extend your desktop app with UWP projects and Windows Runtime components.

In many cases you can call Windows Runtime APIs directly from your desktop application, so before you review this guide, see Enhance for Windows.

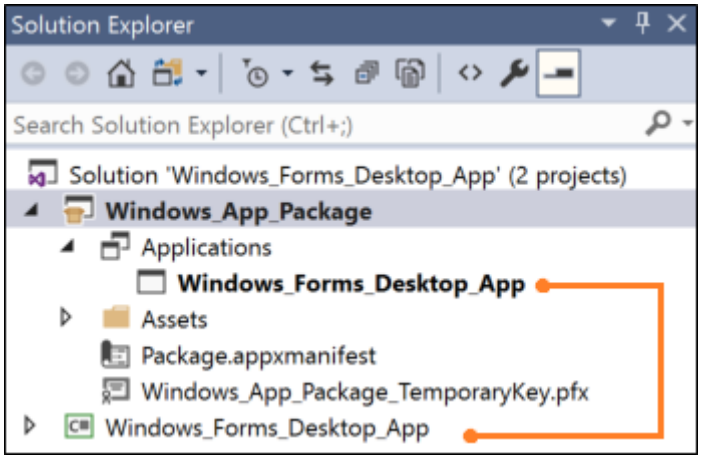
> **Note**
>
> The features described in this topic require that your app is packaged (has package identity at runtime). That includes packaged apps (see Create a new project for a packaged WinUI 3 desktop app) and packaged apps with external location (see Grant package identity by packaging with external location). Also see Features that require package identity.

First, set up your solution

Add one or more UWP projects and runtime components to your solution.

Start with a solution that contains a **Windows Application Packaging Project** with a reference to your desktop application.

This image shows an example solution.



If your solution doesn't contain a packaging project, see Package your desktop application by using Visual Studio.

Configure the desktop application

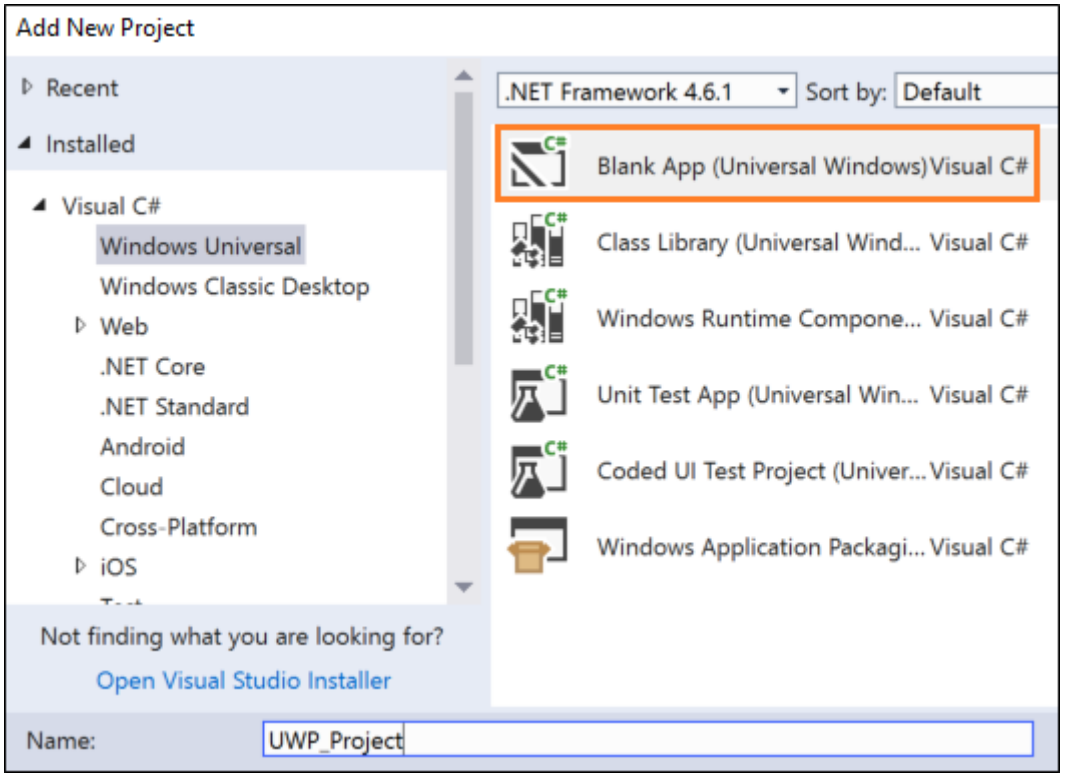
Make sure that your desktop application has references to the files that you need to call Windows Runtime APIs.

To do this, see Call Windows Runtime APIs in desktop apps.

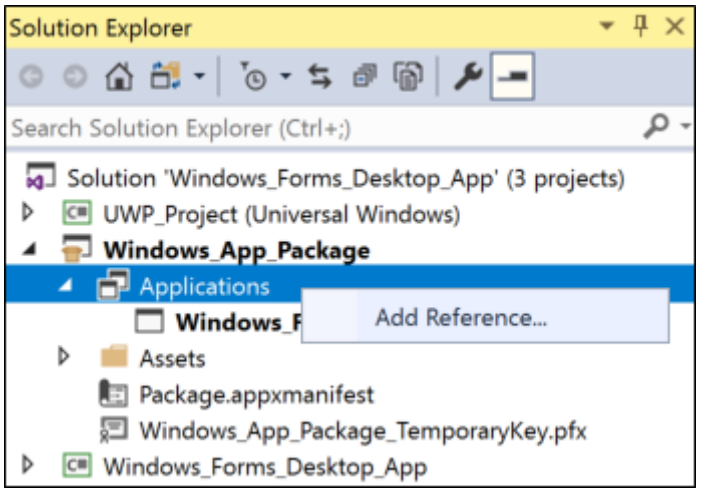
Add a UWP project

Add a **Blank App (Universal Windows)** to your solution.

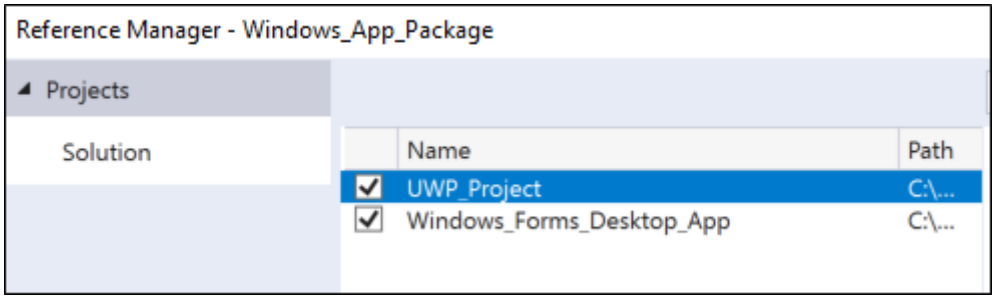
This is where you'll build a modern XAML UI or use APIs that run only within a UWP process.



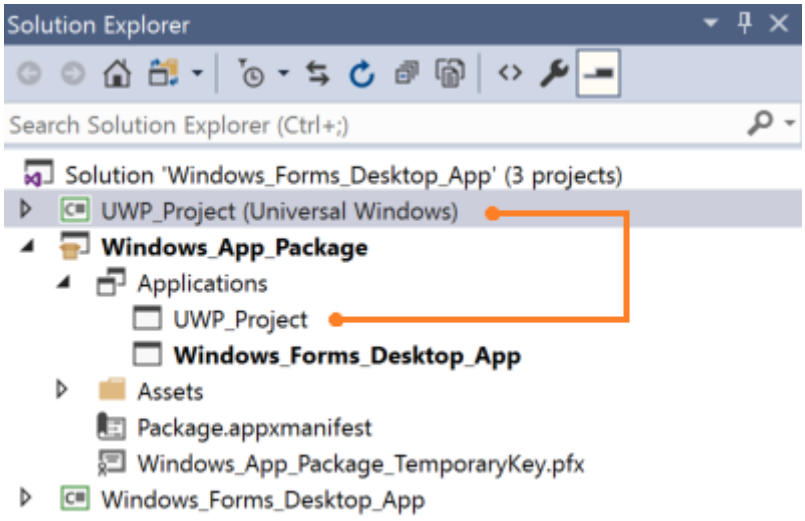
In your packaging project, right-click the **Applications** node, and then click **Add Reference**.



Then, add a reference the UWP project.

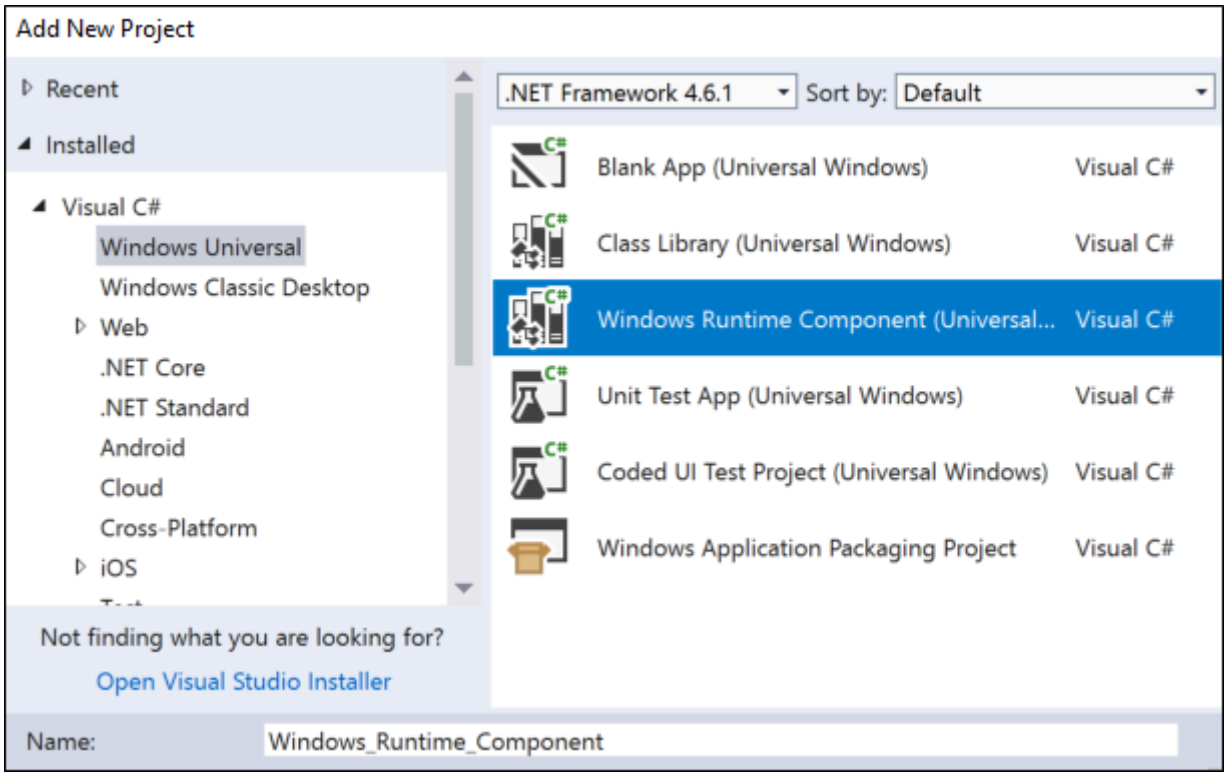


Your solution will look something like this:

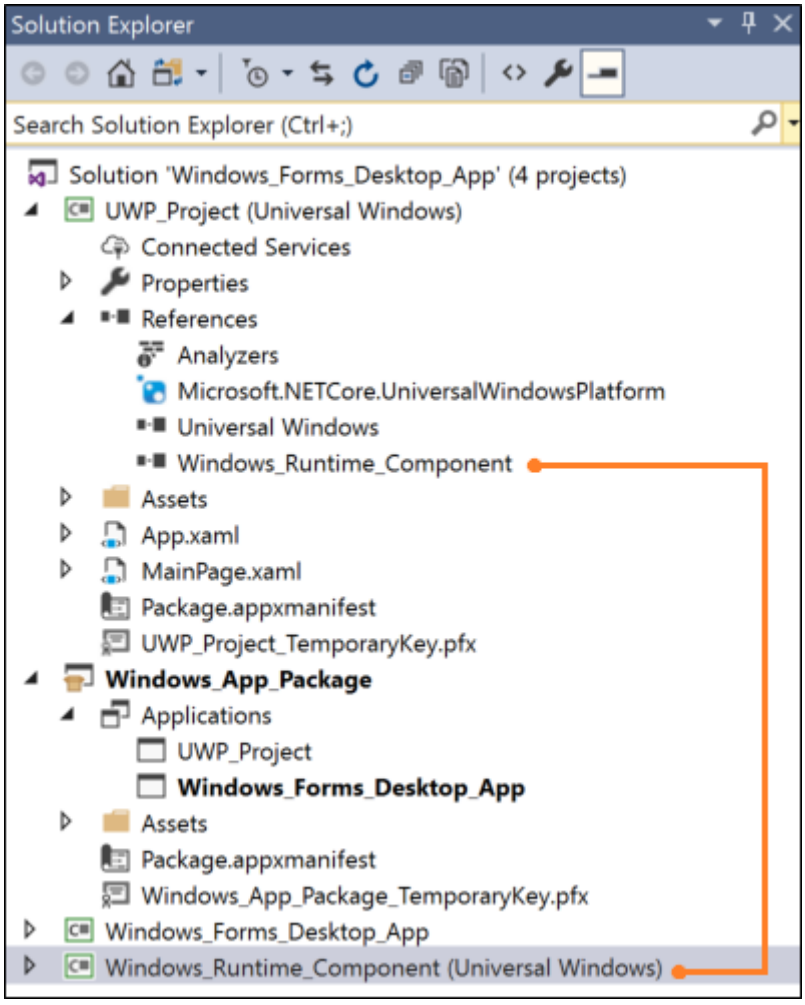


(Optional) Add a Windows Runtime component

To accomplish some scenarios, you'll have to add code to a Windows Runtime component.

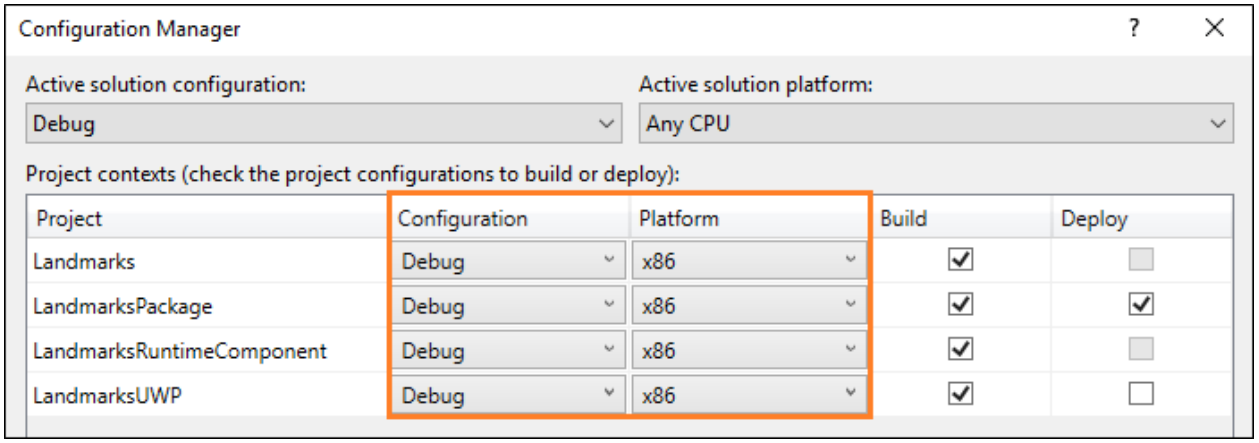


Then, from your UWP project, add a reference to the runtime component. Your solution will look something like this:



Build your solution

Build your solution to ensure that no errors appear. If you receive errors, open **Configuration Manager** and ensure that your projects target the same platform.



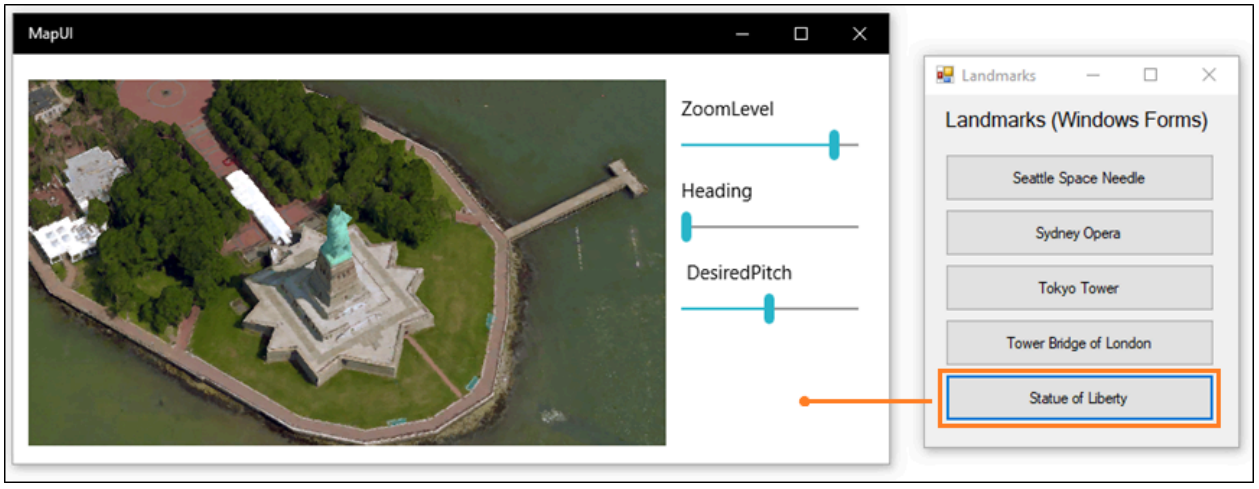
Let's take a look at a few things you can do with your UWP projects and runtime components.

Show a modern XAML UI

As part of your application flow, you can incorporate modern XAML-based user interfaces into your desktop application. These user interfaces are naturally adaptive to different screen sizes and resolutions and support modern interactive models such as touch and ink.

For example, with a small amount of XAML markup, you can give users with powerful map-related visualization features.

This image shows a Windows Forms application that opens a XAML-based modern UI that contains a map control.



Note

This example shows a XAML UI by adding a UWP project to the solution. That is the stable supported approach to showing XAML UIs in a desktop application. The alternative to this approach is to add UWP XAML controls directly to your desktop application by using a XAML Island. XAML Islands are currently available as a developer preview. Although we encourage you to try them out in your own prototype code now, we do not recommend that you use them in production code at this time. These APIs and controls will continue to mature and stabilize in future Windows releases. To learn more about XAML Islands, see UWP controls in desktop applications

The design pattern

To show a XAML-based UI, do these things:

1 Set up your solution

2 Create a XAML UI

3 Add a protocol extension to the UWP project

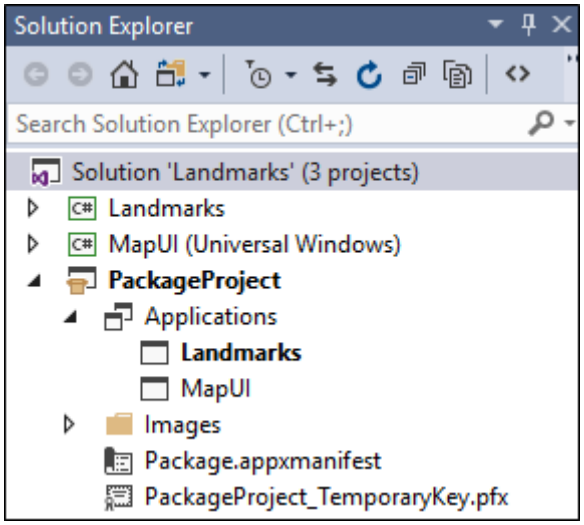
4 Start the UWP app from your desktop app

5 In the UWP project, show the page that you want

Set up your solution

For general guidance on how to set up your solution, see the First, set up your solution section at the beginning of this guide.

Your solution would look something like this:



In this example, the Windows Forms project is named **Landmarks** and the UWP project that contains the XAML UI is named **MapUI**.

Create a XAML UI

Add a XAML UI to your UWP project. Here's the XAML for a basic map.

XML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}"
Margin="12,20,12,14">
    <Grid.ColumnDefinitions>
        <ColumnDefinition Width="Auto"/>
        <ColumnDefinition Width="*"/>
    </Grid.ColumnDefinitions>
    <maps:MapControl x:Name="myMap" Grid.Column="0" Width="500" Height="500"
                     ZoomLevel="{Binding ElementName=zoomSlider,Path=Value,
Mode=TwoWay}"
                     Heading="{Binding ElementName=headingSlider,Path=Value,
Mode=TwoWay}"
                     DesiredPitch="{Binding
ElementName=desiredPitchSlider,Path=Value, Mode=TwoWay}"
                     HorizontalAlignment="Left"
                     MapServiceToken="<Your Key Goes Here" />
    <Grid Grid.Column="1" Margin="12">
        <StackPanel>
            <Slider Minimum="1" Maximum="20" Header="ZoomLevel"
Name="zoomSlider" Value="17.5"/>
            <Slider Minimum="0" Maximum="360" Header="Heading"
Name="headingSlider" Value="0"/>
            <Slider Minimum="0" Maximum="64" Header=" DesiredPitch"
Name="desiredPitchSlider" Value="32"/>
        </StackPanel>
    </Grid>
</Grid>
```

Add a protocol extension

In **Solution Explorer**, open the **package.appxmanifest** file of the Packaging project in your solution, and add this extension.

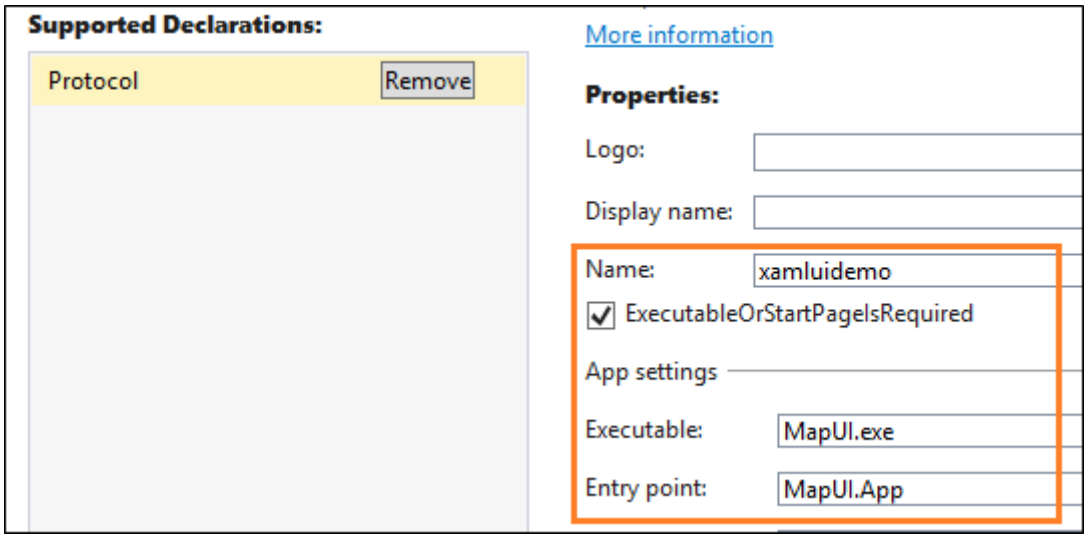
XML

```
<Extensions>
  <uap:Extension Category="windows.protocol" Executable="MapUI.exe"
EntryPoint="MapUI.App">
    <uap:Protocol Name="xamluidemo" />
```

```
  </uap:Extension>
</Extensions>
```

Give the protocol a name, provide the name of the executable produced by the UWP project, and the name of the entry point class.

You can also open the **package.appxmanifest** in the designer, choose the **Declarations** tab, and then add the extension there.



> ⓘ Note
>
> Map controls download data from the internet so if you use one, you'll have to add the "internet client" capability to your manifest as well.

Start the UWP app

First, from your desktop application, create a Uri that includes the protocol name and any parameters you want to pass into the UWP app. Then, call the LaunchUriAsync method.

C#

```
private void Statue_Of_Liberty_Click(object sender, EventArgs e)
{
    ShowMap(40.689247, -74.044502);
}

private async void ShowMap(double lat, double lon)
{
    string str = "xamluidemo://";

    Uri uri = new Uri(str + "location?lat=" +
```

```
        lat.ToString() + "&?lon=" + lon.ToString());

    var success = await Windows.System.Launcher.LaunchUriAsync(uri);

}
```

Parse parameters and show a page

In the **App** class of your UWP project, override the **OnActivated** event handler. If the app is activated by your protocol, parse the parameters and then open the page that you want.

C#

```
protected override void
OnActivated(Windows.ApplicationModel.Activation.IActivatedEventArgs e)
{
    if (e.Kind == ActivationKind.Protocol)
    {
        ProtocolActivatedEventArgs protocolArgs =
(ProtocolActivatedEventArgs)e;
        Uri uri = protocolArgs.Uri;
        if (uri.Scheme == "xamluidemo")
        {
            Frame rootFrame = new Frame();
            Window.Current.Content = rootFrame;
            rootFrame.Navigate(typeof(MainPage), uri.Query);
            Window.Current.Activate();
        }
    }
}
```

In the code behind your XAML page, override the `OnNavigatedTo` method to use the parameters passed into the page. In this case, we'll use the latitude and longitude that were passed into this page to show a location in a map.

C#

```
protected override void OnNavigatedTo(NavigationEventArgs e)
 {
     if (e.Parameter != null)
     {
         WwwFormUrlDecoder decoder = new
WwwFormUrlDecoder(e.Parameter.ToString());

         double lat = Convert.ToDouble(decoder[0].Value);
         double lon = Convert.ToDouble(decoder[1].Value);

         BasicGeoposition pos = new BasicGeoposition();
```

```
            pos.Latitude = lat;
            pos.Longitude = lon;

            myMap.Center = new Geopoint(pos);

            myMap.Style = MapStyle.Aerial3D;

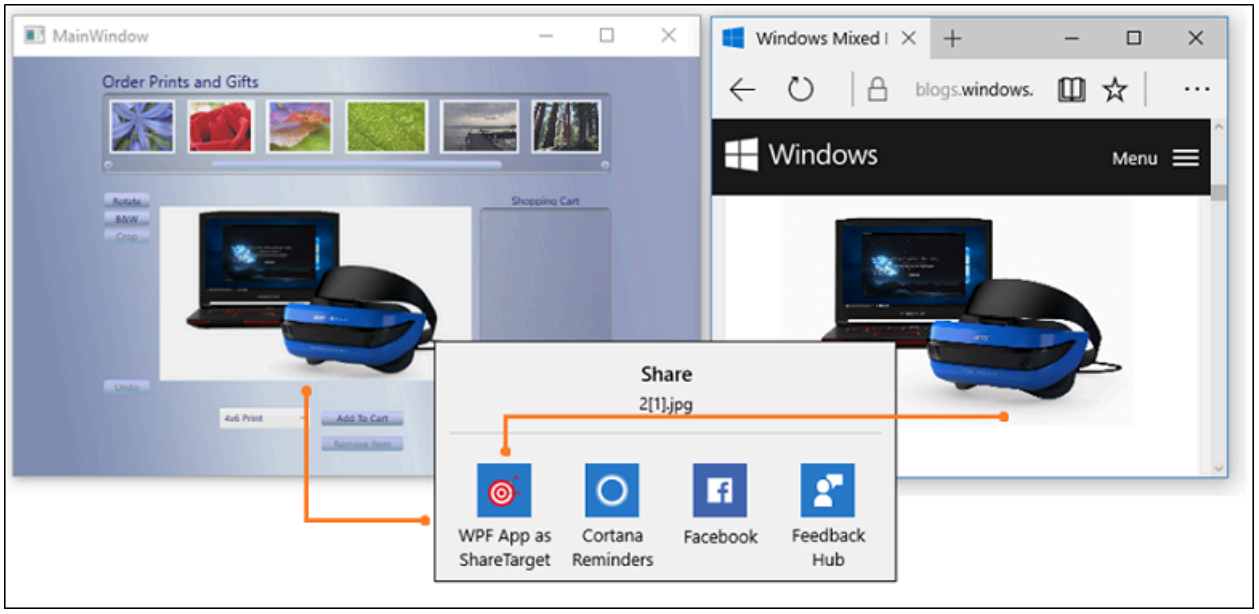
        }

        base.OnNavigatedTo(e);
    }
```

Making your desktop application a share target

You can make your desktop application a share target so that users can easily share data such as pictures from other apps that support sharing.

For example, users could choose your application to share pictures from Microsoft Edge, the Photos app. Here's a WPF sample application that has that capability.



.

See the complete sample here

The design pattern

To make your application a share target, do these things:

[1] Add a share target extension

[2] Override the OnShareTargetActivated event handler

3 Add desktop extensions to the UWP project

4 Add the full trust process extension

5 Modify the desktop application to get the shared file

The following steps

Add a share target extension

In **Solution Explorer**, open the **package.appxmanifest** file of the Packaging project in your solution and add the share target extension.

XML

```
<Extensions>
      <uap:Extension
          Category="windows.shareTarget"
          Executable="ShareTarget.exe"
          EntryPoint="App">
        <uap:ShareTarget>
          <uap:SupportedFileTypes>
            <uap:SupportsAnyFileType />
          </uap:SupportedFileTypes>
          <uap:DataFormat>Bitmap</uap:DataFormat>
        </uap:ShareTarget>
      </uap:Extension>
</Extensions>
```

Provide the name of the executable produced by the UWP project, and the name of the entry point class. This markup assumes that the name of the executable for your UWP app is `ShareTarget.exe`.

You'll also have to specify what types of files can be shared with your app. In this example, we are making the WPF PhotoStoreDemo desktop application a share target for bitmap images so we specify `Bitmap` for the supported file type.

Override the OnShareTargetActivated event handler

Override the **OnShareTargetActivated** event handler in the **App** class of your UWP project.

This event handler is called when users choose your app to share their files.

C#

```
protected override void OnShareTargetActivated(ShareTargetActivatedEventArgs
args)
{
    shareWithDesktopApplication(args.ShareOperation);
}

private async void shareWithDesktopApplication(ShareOperation
shareOperation)
{
    if (shareOperation.Data.Contains(StandardDataFormats.StorageItems))
    {
        var items = await shareOperation.Data.GetStorageItemsAsync();
        StorageFile file = items[0] as StorageFile;
        IRandomAccessStreamWithContentType stream = await
file.OpenReadAsync();

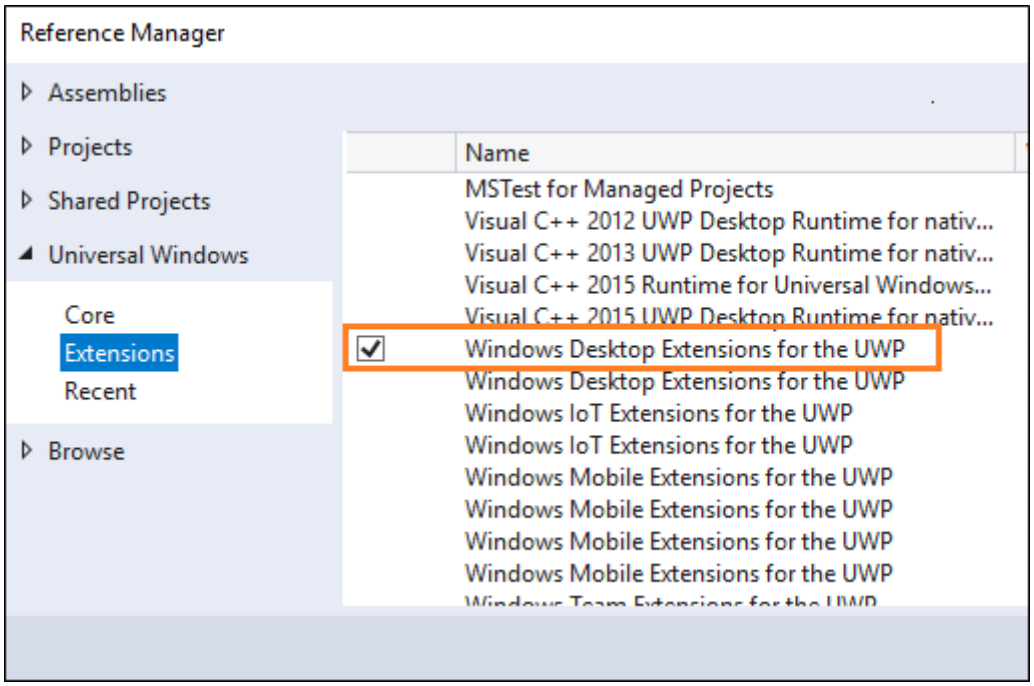
        await file.CopyAsync(ApplicationData.Current.LocalFolder);
            shareOperation.ReportCompleted();

        await
FullTrustProcessLauncher.LaunchFullTrustProcessForCurrentAppAsync();
    }
}
```

In this code, we save the image that is being shared by the user into a apps local storage folder. Later, we'll modify the desktop application to pull images from that same folder. The desktop application can do that because it is included in the same package as the UWP app.

Add desktop extensions to the UWP project

Add the **Windows Desktop Extensions for the UWP** extension to the UWP app project. You'll see more than one version of the extension (for example, 10.0.18362.0 and 10.0.19041.0). For info about how to choose a version, see Extension SDKs, and how to reference them.



Add the full trust process extension

In **Solution Explorer**, open the **package.appxmanifest** file of the Packaging project in your solution, and then add the full trust process extension next to the share target extension that you add this file earlier.

XML

```
<Extensions>
  ...
      <desktop:Extension Category="windows.fullTrustProcess"
Executable="PhotoStoreDemo\PhotoStoreDemo.exe" />
  ...
</Extensions>
```

This extension will enable the UWP app to start the desktop application to which you would like the share a file. In example, we refer to the executable of the WPF PhotoStoreDemo desktop application.

Modify the desktop application to get the shared file

Modify your desktop application to find and process the shared file. In this example, the UWP app stored the shared file in the local app data folder. Therefore, we would modify the WPF PhotoStoreDemo desktop application to pull photos from that folder.

C#

```
Photos.Path = Windows.Storage.ApplicationData.Current.LocalFolder.Path;
```

For instances of the desktop application that are already open by the user, we might also handle the FileSystemWatcher event and pass in the path to the file location. That way any open instances of the desktop application will show the shared photo.

C#

```
...

   FileSystemWatcher watcher = new FileSystemWatcher(Photos.Path);

...

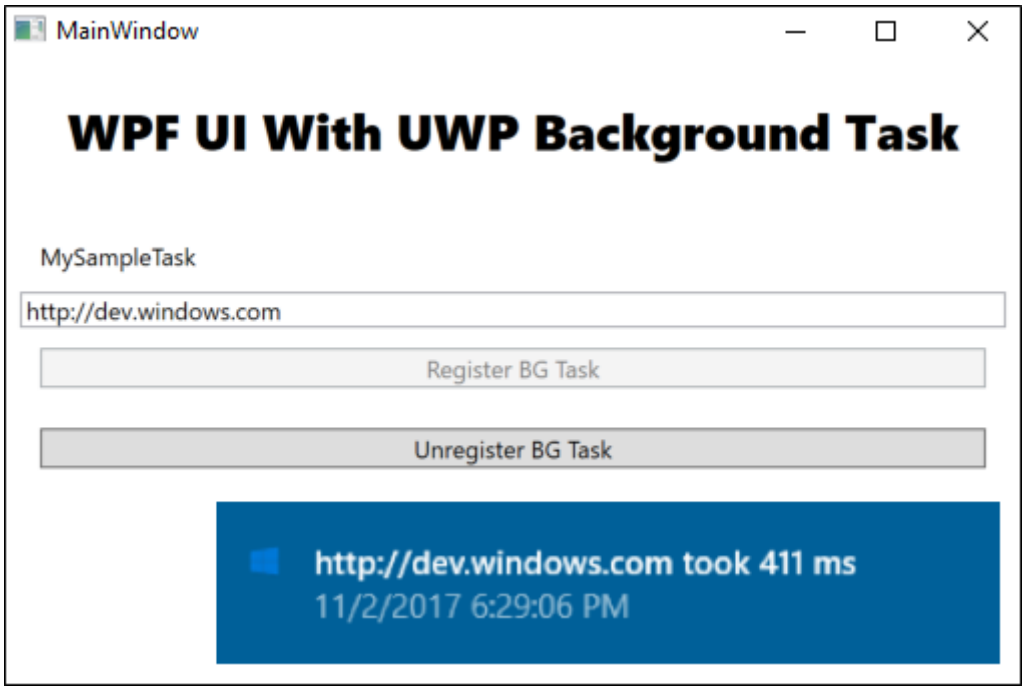
private void Watcher_Created(object sender, FileSystemEventArgs e)
{
    // new file got created, adding it to the list

Dispatcher.BeginInvoke(System.Windows.Threading.DispatcherPriority.Normal,
new Action(() =>
    {
        if (File.Exists(e.FullPath))
        {
            ImageFile item = new ImageFile(e.FullPath);
            Photos.Insert(0, item);
            PhotoListBox.SelectedIndex = 0;
            CurrentPhoto.Source = (BitmapSource)item.Image;
        }
    }));
}
```

Create a background task

You add a background task to run code even when the app is suspended. Background tasks are great for small tasks that don't require the user interaction. For example, your task can download mail, show a toast notification about an incoming chat message, or react to a change in a system condition.

Here's a WPF sample application that registers a background task.



The task makes an http request and measures the time that it takes for the request to return a response. Your tasks will likely be much more interesting, but this sample is great for learning the basic mechanics of a background task.

See the complete sample here.

The design pattern

To create a background service, do these things:

1. Implement the background task
2. Configure the background task
3. Register the background task

Implement the background task

Implement the background task by adding code to a Windows Runtime component project.

C#

```
public sealed class SiteVerifier : IBackgroundTask
{
    public async void Run(IBackgroundTaskInstance taskInstance)
    {

        taskInstance.Canceled += TaskInstance_Canceled;
        BackgroundTaskDeferral deferral = taskInstance.GetDeferral();
```

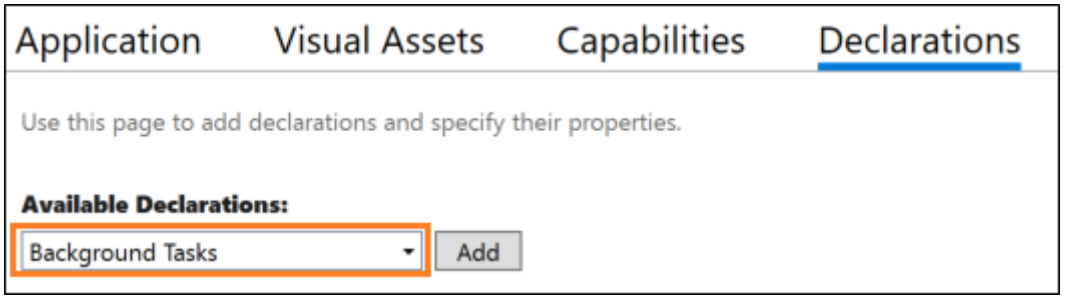
```
            var msg = await MeasureRequestTime();
            ShowToast(msg);
            deferral.Complete();
        }

        private async Task<string> MeasureRequestTime()
        {
            string msg;
            try
            {
                var url =
ApplicationData.Current.LocalSettings.Values["UrlToVerify"] as string;
                var http = new HttpClient();
                Stopwatch clock = Stopwatch.StartNew();
                var response = await http.GetAsync(new Uri(url));
                response.EnsureSuccessStatusCode();
                var elapsed = clock.ElapsedMilliseconds;
                clock.Stop();
                msg = $"{url} took {elapsed.ToString()} ms";
            }
            catch (Exception ex)
            {
                msg = ex.Message;
            }
            return msg;
        }
```

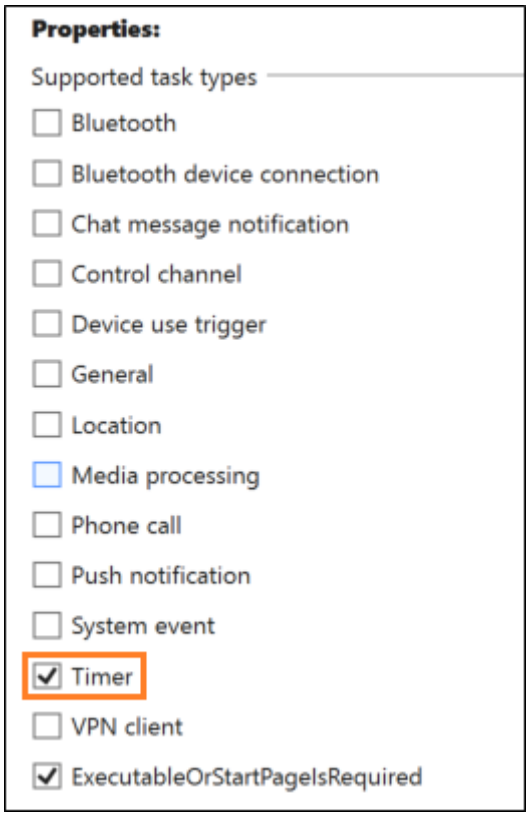
Configure the background task

In the manifest designer, open the **package.appxmanifest** file of the Packaging project in your solution.

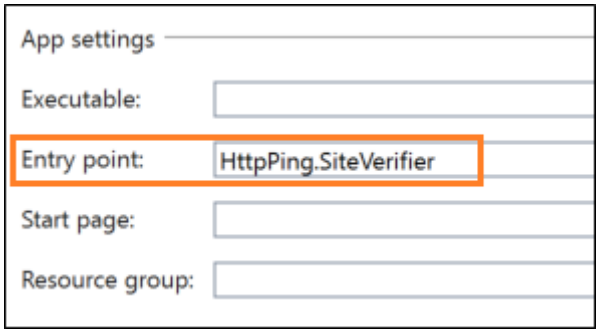
In the **Declarations** tab, add a **Background Tasks** declaration.



Then, choose the desired properties. Our sample uses the **Timer** property.



Provide the fully qualified name of the class in your Windows Runtime component that implements the background task.



Register the background task

Add code to your desktop application project that registers the background task.

C#

```
public void RegisterBackgroundTask(String triggerName)
{
    var current = BackgroundTaskRegistration.AllTasks
        .Where(b => b.Value.Name == triggerName).FirstOrDefault().Value;

    if (current is null)
    {
        BackgroundTaskBuilder builder = new BackgroundTaskBuilder();
        builder.Name = triggerName;
        builder.SetTrigger(new MaintenanceTrigger(15, false));
        builder.TaskEntryPoint = "HttpPing.SiteVerifier";
```

```
        builder.Register();
        System.Diagnostics.Debug.WriteLine("BGTask registered:" +
triggerName);
    }
    else
    {
        System.Diagnostics.Debug.WriteLine("Task already:" + triggerName);
    }
}
```

Distribute your packaged desktop app

Article • 10/05/2022

If you decide to package your desktop app in an MSIX package (see Building an MSIX package from your code), you can publish your packaged application to the Microsoft Store or sideload it on to one or more devices.

> **Note**
>
> Do you have a plan for how you might transition users to your packaged application? Before you distribute your app, see the **Transition users to your packaged app** section of this guide to get some ideas.

Distribute your application by publishing it to the Microsoft Store

The Microsoft Store is a convenient way for customers to get your app.

Publish your application to the Microsoft Store to reach the broadest audience. Also, organizational customers can acquire your application to distribute internally to their organizations through the Microsoft Store for Business.

If you plan to publish to the Microsoft Store, you'll be asked a few extra questions as part of the submission process. That's because your package manifest declares a restricted capability named **runFullTrust**, and we need to approve your application's use of that capability. You can read more about this requirement here: Restricted capabilities.

You don't have to sign your application before you submit it to the Store.

> **Important**
>
> If you plan to publish your application to the Microsoft Store, make sure that your application operates correctly on devices that run Windows 10 S or Windows 11 S. This is a Store requirement. See **Test your Windows app for Windows 10 S or Windows 11 S**.

Distribute your application without placing it onto the Microsoft Store

If you'd rather distribute your application without using the Store, you can manually distribute apps to one or more devices.

This might make sense if you want greater control over the distribution experience or you don't want to get involved with the Microsoft Store certification process.

To distribute your application to other devices without placing it in the Store, you have to obtain a certificate, sign your application by using that certificate, and then sideload your application onto those devices.

You can create a certificate or obtain one from a popular vendor such as Verisign.

If you plan to distribute your application onto devices that run Windows 10 S or Windows 11 S, your application has to be signed by the Microsoft Store so you'll have to go through the Store submission process before you can distribute your application onto those devices.

If you create a certificate, you have to install it into the **Trusted Root** or **Trusted People** certificate store on each device that runs your app. If you get a certificate from a popular vendor, you won't have to install anything onto other systems besides your app.

> **Important**
>
> Make sure that the publisher name on your certificate matches the publisher name of your app.

To sign your application by using a certificate, see Sign an application package using SignTool.

To sideload your application onto other devices, see Sideload LOB apps in Windows.

Transition users to your packaged app

Before you distribute your app, consider adding a few extensions to your package manifest to help users get into the habit of using your packaged app. Here's a few things you can do.

- Point existing Start tiles and taskbar buttons to your packaged app.
- Associate your packaged application with a set of file types.

- Make your packaged application open certain types of files by default.

For the complete list of extensions and the guidance for how to use them, see Transition users to your app.

Also, consider adding code to your packaged application that accomplishes these tasks:

- Migrates user data associated with your desktop application to the appropriate folder locations of your packaged app.
- Gives users the option to uninstall the desktop version of your app.

Let's talk about each one of these tasks. We'll start with user data migration.

Migrate user data

If you're going to add code that migrates user data, it's best to run that code only when the application is first started. Before you migrate the users data, display a dialog box to the user that explains what is happening, why it is recommended, and what's going to happen to their existing data.

Here's an example of how you could do this in a .NET-based packaged app.

C#

```
private void MigrateUserData()
{
    String sourceDir = Environment.GetFolderPath
        (Environment.SpecialFolder.ApplicationData) + "\\AppName";

    if (sourceDir != null)
    {
        DialogResult migrateResult = MessageBox.Show
            ("Would you like to migrate your data from the previous version
of this app?",
             "Data Migration", MessageBoxButtons.YesNo);

        if (migrateResult.Equals(DialogResult.Yes))
        {
            String destinationDir =
                Windows.Storage.ApplicationData.Current.LocalFolder.Path +
"\\AppName";

            Process process = new Process();
            process.StartInfo.FileName = "robocopy.exe";
            process.StartInfo.Arguments = "%LOCALAPPDATA%\\AppName " +
destinationDir + " /move";
            process.StartInfo.CreateNoWindow = true;
            process.Start();
            process.WaitForExit();
```

```
            if (process.ExitCode > 1)
            {
                //Migration was unsuccessful -- you can choose to
block/retry/other action
            }
        }
    }
}
```

Uninstall the desktop version of your app

It is better not to uninstall the users desktop application without first asking them for permission. Display a dialog box that asks the user for that permission. Users might decide not to uninstall the desktop version of your app. If that happens, you'll have to decide whether you want to block usage of the desktop application or support the side-by-side use of both apps.

Here's an example of how you could do this in a .NET-based packaged app.

To view the complete context of this snippet, see the **MainWindow.cs** file of this sample WPF picture viewer with transition/migration/uninstallation.

C#

```
private void RemoveDesktopApp()
{
    //Typically, you can find your uninstall string at this location.
    String uninstallString = (String)Microsoft.Win32.Registry.GetValue

(@"HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\Windows\CurrentVersion"
+
         @"\Uninstall\{7AD02FB8-B85E-44BC-8998-F4803BA5A0E3}\",
"UninstallString", null);

    //Detect if the previous version of the Desktop application is
installed.
    if (uninstallString != null)
    {
        DialogResult uninstallResult = MessageBox.Show
            ("To have the best experience, consider uninstalling the "
              + " previous version of this app. Would you like to do that
now?",
              "Uninstall the previous version", MessageBoxButtons.YesNo);

        if (uninstallResult.Equals(DialogResult.Yes))
        {
                    string[] uninstallArgs = uninstallString.Split(' ');

            Process process = new Process();
```

```
            process.StartInfo.FileName = uninstallArgs[0];
            process.StartInfo.Arguments = uninstallArgs[1];
            process.StartInfo.CreateNoWindow = true;

            process.Start();
            process.WaitForExit();

            if (process.ExitCode != 0)
            {
                //Uninstallation was unsuccessful - You can choose to block
the application here.
            }
        }
    }

}
```

If you encounter issues publishing your application to the Store, this blog post contains some useful tips.

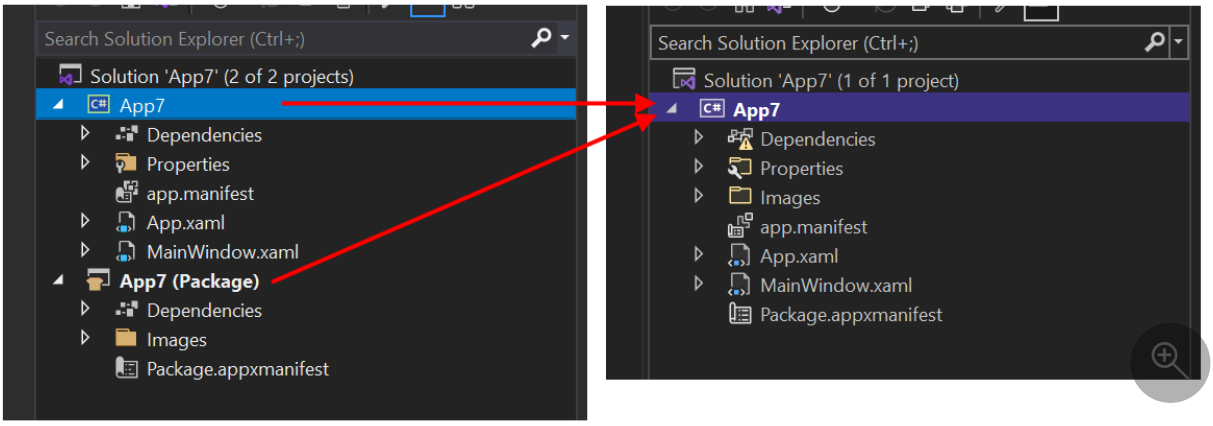
Package your app using single-project MSIX

Article • 02/03/2023

Single-project MSIX is a feature that lets you build a packaged WinUI 3 desktop app without the need for a separate packaging project. A WinUI 3 app is one that uses the WinUI 3 framework for its user interface (UI); and it uses the Windows App SDK. To package a desktop app that's *not* a WinUI 3 app, see Set up your desktop application for MSIX packaging in Visual Studio.

The single-project MSIX feature is available as a Visual Studio extension that you can use for these scenarios:

- Create a *new* WinUI 3 desktop app using the **Blank App, Packaged (WinUI 3 in Desktop)** Visual Studio project template that comes with the Windows App SDK. That project is configured to build your app into an MSIX package without needing a separate packaging project.
- Modify an *existing* WinUI 3 desktop app that uses a separate packaging project. The modification involves removing the separate packaging project, as shown in the illustration below.



Overview

This section introduces some important details about the single-project MSIX feature.

Benefits

Before the introduction of the single-project MSIX feature, if you wanted to build a packaged WinUI 3 desktop app, then you needed two projects in your solution—your app project, plus an additional **Windows Application Packaging Project** (see Set up

your desktop application for MSIX packaging in Visual Studio). The single-project MSIX feature enables you to develop and build your app using only a project for your app. That provides a cleaner project structure and a more straightforward development experience. For example, you no longer need to select the separate packaging project as your startup project.

Supported project types

The single-project MSIX feature supports WinUI 3 templates in Visual Studio (C# and C++) for the Windows App SDK.

Limitations

Single-project MSIX supports only a single executable in the generated MSIX package. If you need to combine multiple executables into a single MSIX package, then you'll need to continue using a Windows Application Packaging Project in your solution.

Install the single-project MSIX packaging tools

The single-project MSIX packaging tools include Visual Studio project templates that you can use to create new packaged WinUI 3 desktop apps. Those tools are included with the Windows App SDK extension for Visual Studio. For installation instructions for the Windows App SDK, see Install tools for the Windows App SDK.

Windows App SDK 0.8 and C# version of 1.0 Preview 3: The single-project MSIX packaging tools are *not* included with the Windows App SDK extension for Visual Studio for Windows App SDK version 0.8, or for C# projects with up to and including Preview 3 of the Windows App SDK 1.0. So if you're using those versions, then you *might* need to explicitly install the single-project MSIX packaging tools. See the info below:

- **Visual Studio 2022 version 17.1 and later:** The Single-project MSIX Packaging Tools for Visual Studio 2022 VSIX extension is built into Visual Studio 2022 version 17.1 and later.
- **Visual Studio 2022 prior to version 17.1:** Install the Single-project MSIX Packaging Tools for Visual Studio 2022 VSIX extension.
- **Visual Studio 2019:** Install the Single-project MSIX Packaging Tools for Visual Studio 2019 VSIX extension. The extension requires Visual Studio 2019 version 16.10.x or later.

You can then, in Visual Studio, confirm that you have the extension installed. Click **Extensions** > **Manage Extensions** > **Installed** > **All**, and confirm that *Single-project MSIX Packaging Tools* is listed.

Create a new project

If you're using Windows App SDK 1.0 Preview 2 or later, then you can create a new WinUI 3-based app that includes single-project MSIX support simply by using the **Blank App, Packaged (WinUI 3 in Desktop)** template. For more information, see Create your first WinUI 3 project.

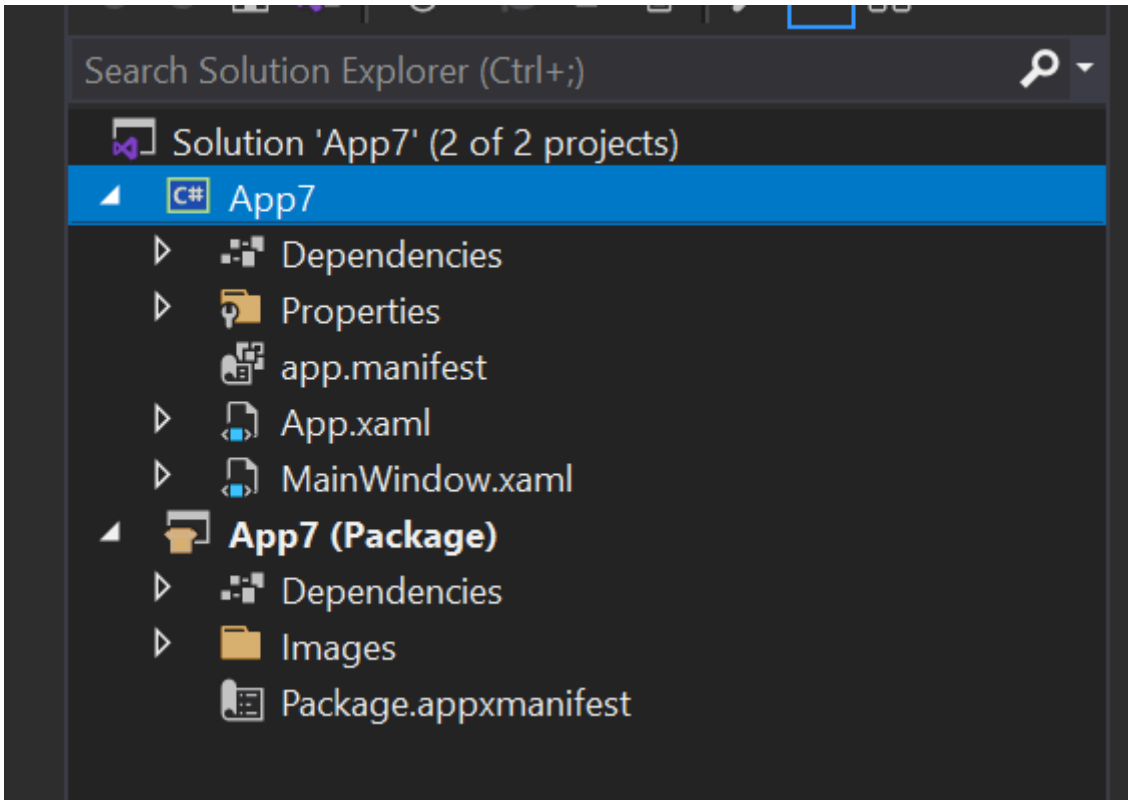
Modify an existing project

Follow the steps in this section to modify an existing WinUI 3-based app that uses a separate packaging project. The steps include moving the package manifest (and other support needed to build an MSIX package) into the application project, and then removing the separate packaging project.

Step 1: Create or open an existing packaging project

If you already have a solution for a WinUI 3 desktop app (see WinUI 3 templates in Visual Studio) that includes a **Windows Application Packaging Project** (see Set up your desktop application for MSIX packaging in Visual Studio), then open that solution in Visual Studio now.

If not, then create a new WinUI 3 desktop app in Visual Studio by using the **Blank App, Packaged with Windows Application Packaging Project (WinUI 3 in Desktop)** template. Your solution will look similar to the screenshot below.



Step 2: Edit the application project settings

Next, edit some configuration settings to use the single-project MSIX feature. There are different instructions depending on your project type and Visual Studio version.

C#

1. In **Solution Explorer**, double-click the project node for your application to open the **.csproj** file in the XML editor. Add the following XML to the main **<PropertyGroup>** element.

   XML

   ```
   <EnableMsixTooling>true</EnableMsixTooling>
   <PublishProfile>Properties\PublishProfiles\win10-$(Platform).pubxml
   </PublishProfile>
   ```

   When you're done, the **<PropertyGroup>** element should look similar to this.

   XML

   ```
   <Project Sdk="Microsoft.NET.Sdk">
     <PropertyGroup>
       <OutputType>WinExe</OutputType>
       <TargetFramework>net8.0-windows10.0.19041.0</TargetFramework>
       ...
   ```

```
    <UseWinUI>true</UseWinUI>
    <EnableMsixTooling>true</EnableMsixTooling>

<PublishProfile>Properties\PublishProfiles\win10-$(Platform).pubxml
</PublishProfile>
  </PropertyGroup>
```

2. Save your changes, and close the **.csproj** file.

3. Perform one of the following procedures, depending on your version of Visual Studio.

   For Visual Studio 2022 or later:

   a. In **Solution Explorer**, right-click the **Properties** folder under the project node for your application, and select **Add** > **New Item...**.

   b. Select **Text File**, name the new file **launchSettings.json**, and click **Add**. Make sure the new file is in the **Properties** folder of your application project.

   c. Copy the following settings into the new file. You're free to change the values as needed for your scenario. The **MyApp** value can be any string; it doesn't need to match the name of your application.

   JSON

```
{
    "profiles": {
        "MyApp": {
            "commandName": "MsixPackage",
            "commandLineArgs": "", /* Command line arguments to
pass to the app. */
            "alwaysReinstallApp": false, /* Uninstall and then
reinstall the app. All information about the app state is
deleted. */
            "remoteDebugEnabled": false, /* Indicates that the
debugger should attach to a process on a remote machine. */
            "allowLocalNetworkLoopbackProperty": true, /* Allow
the app to make network calls to the device it is installed on.
*/
            "authenticationMode": "Windows", /* The
authentication scheme to use when connecting to the remote
machine. */
            "doNotLaunchApp": false, /* Do not launch the app,
but debug my code when it starts. */
            "remoteDebugMachine": "", /* The name of the remote
machine. */
            "nativeDebugging": false /* Enable debugging for
managed and native code together, also known as mixed-mode
debugging. */
        }
```

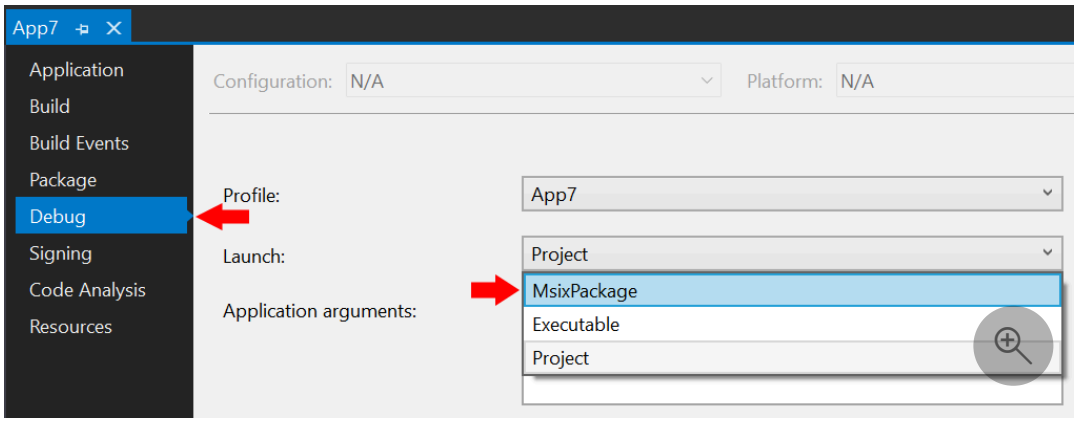
```
    }
}
```

d. Save and close the **launchSettings.json** file.

For Visual Studio 2019:

a. In **Solution Explorer**, right-click the project node for your application, and select **Properties**.

b. Select the **Debug** tab and set the **Launch** property to **MsixPackage**. You might have to select this twice if it reverts back on the first attempt.



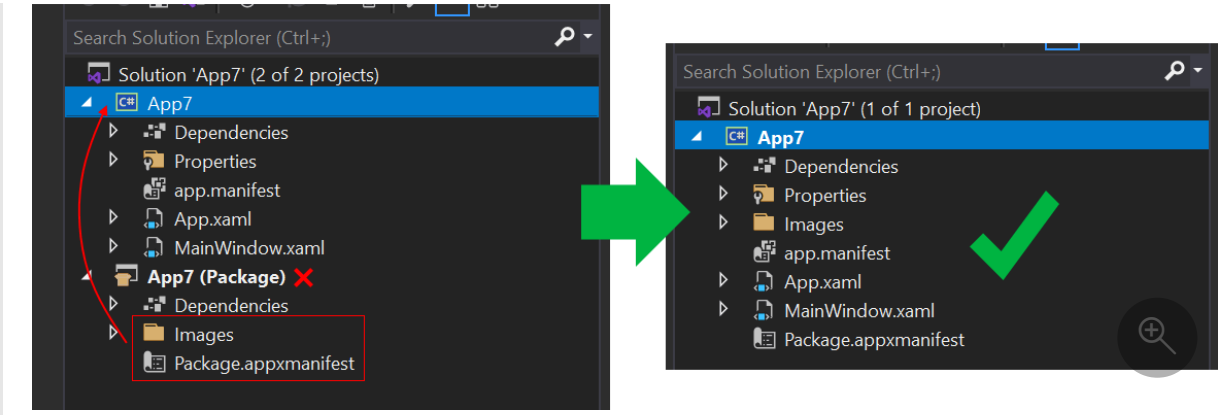
c. Save your changes.

Step 3: Move files to the application project

Next, move several important files to the application project. There are different instructions depending on your project type.

C#

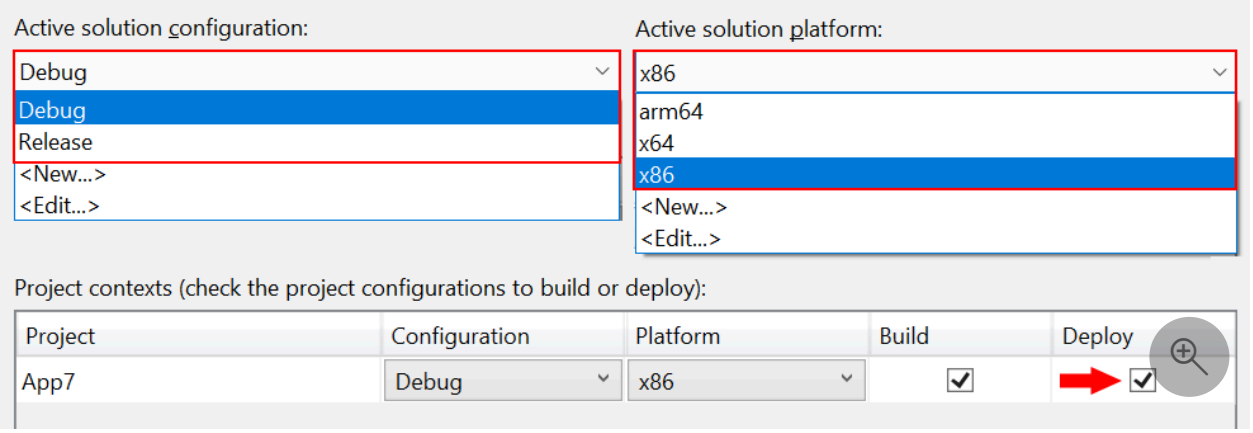
1. In **File Explorer**, move the **Package.appxmanifest** file and the **Images** folder from your packaging project to your application project. Place this file and folder in the top level of the application project's folder hierarchy.
2. In Visual Studio, in **Solution Explorer**, multi-select all of the images inside the **Images** folder. In the **Properties** window, set **Build Action** to *Content*.
3. Remove the packaging project from your solution.



Step 4: Enable deploying in Configuration Manager

1. Select **Build** > **Configuration Manager**.
2. In **Configuration Manager**, click the **Deploy** check box for every combination of configuration and platform (for example, **Debug** and **x86**, **Debug** and **arm64**, **Release** and **x64**, and more).

> ⓘ Note
>
> Be sure to use the **Active solution configuration** and **Active solution platform** drop-downs at the top instead of the **Configuration** and **Platform** drop-downs in the same row as the **Deploy** check box.



Step 5: Deploy your app

Build and deploy your application project. Visual Studio will build your application into an MSIX package, install the package, and then run your application.

Step 6: Package your app for publishing

Use the Package & Publish command in Visual Studio to package your application to publish it to the Microsoft Store.

Automate building and packaging your single-project MSIX app

You can use `msbuild` to build and package your single-project MSIX app, thereby allowing you to automate the workflow. The technique for a single-project solution, and the command-line, is only slightly different from what you might already be doing if you have a two-project solution—one that has a **Windows Application Packaging Project** (see Set up your desktop application for MSIX packaging in Visual Studio).

The important build command option for a single-project solution is `/p:GenerateAppxPackageOnBuild=true`. Without that option, the project will build, but you won't get an MSIX package. Include that option, and that will cause the MSIX package to be generated.

There's a full example in the form of a GitHub Action that builds a WinUI 3 single-project solution.

> **Note**
>
> Single-project MSIX doesn't currently support producing MSIX bundles (see Bundling MSIX packages). It produces only a single MSIX. But you can bundle `.msix` files into an MSIX bundle by using the MSIX Bundler GitHub Action.

How a packaged desktop app runs on Windows

For a deeper dive on what happens to files and registry entries when you create a Windows app package for your desktop application, see Understanding how packaged desktop apps run on Windows.

Provide feedback

To send us your feedback, report problems, or ask questions about the single-project MSIX feature, post a discussion or issue on the Windows App SDK GitHub repository.

Grant package identity by packaging with external location

Article • 05/22/2025

Many Windows features can be used by a desktop app only if that app has package identity at runtime. See Features that require package identity. If you have an existing desktop app, with its own installer, then there's very little you need to change in order to benefit from package identity.

Starting in Windows 10, version 2004, you can grant package identity to an app simply by building and registering a *package with external location* with your app. Packaging with external location allows you to register a simple identity package in your existing installer without changing how or where you install your application. You might be familiar with full MSIX packaging; this is a much lighter-weight option.

You can add an identity package to an existing Visual Studio project with the Windows Application Packaging Project and Package with External Location extension. This approach is recommended when there is a single application project that needs identity. The tooling provides a visual manifest editor, visual Resource Designer for localization, graphical wizard for creating and trusting self-signed certificates, automatic updating of application manifests, and PowerShell scripts to register and unregister the identity package for local testing.

If you don't build with Visual Studio or want to bundle multiple application executables under a shared identity, you can build an identity package manually.

Grant package identity by packaging with external location in Visual Studio

Article • 05/22/2025

For the motivations behind adding package identity, as well as the differences between building identity packages in Visual Studio and building them manually, see Overview.

This topic describes how to build and register an identity package by using Visual Studio. For info about building an identity package manually, see Grant package identity by packaging with external location manually.

These are the steps (which this topic describes in detail) to build and register an identity package by using Visual Studio:

1. Install Visual Studio components
2. Add a Packaging Project to your solution
3. Configure the Packaging Project for signing
4. Build and test the Packaging Project in Release Mode
5. Register the identity package in your installer
6. Optional steps

Install Visual Studio components

Creating an identity package in Visual Studio requires the **Windows Application Packaging Project** and the **Package with External Location** extension.

Install the **Windows Application Packaging Project** components as described in Required Visual Studio version and workload.

In Visual Studio, via the **Extensions** > **Manage Extensions** menu item, install the **Package with External Location** extension.

Add a Packaging Project to your solution

To add a Packaging Project to your solution with a Project Reference to your application project, see Set up the Windows Application Packaging Project in your solution.

Enable packaging with external location by right-clicking the Packaging Project in Solution Explorer, navigating to the **External Location** tab provided by the **Package with External Location** extension, enabling the **Package with External Location** option, and saving the changes.

Set the **Package name** and **Publisher display name** fields of the identity package by double-clicking `Package.appxmanifest` in the Packaging Project to open the visual manifest editor, navigating to the Packaging tab, and setting the **Package name** and **Publisher display name** fields to the desired values.

If you have a custom application manifest in your application project, then for info about synchronizing the values with the values from `Package.appxmanifest`, see Add identity metadata to your desktop application manifests. The **Package with External Location** extension uses **App** for the **applicationId**.

If you don't have a custom application manifest, then Visual Studio will produce the appropriate artifacts during the build process. .NET projects embed a manifest by default, which conflicts with the produced manifest artifacts. To resolve that, right-click the Project, open **Properties**, and in the **Application** tab under the **Manifest** section, change **Embed manifest with default settings** to **Create application without a manifest**.

Configure the Packaging Project for signing

Generate a certificate for signing by walking through the **Publish** > **Create App Packages** wizard shown in Create an app package using the packaging wizard.

On the first screen, ensure that **Sideloading** is selected, and **Enable automatic updates** is unchecked. On the second screen, create a self-signed certificate if necessary, then click the **Trust** button to trust it in the Local Machine Trusted People certificate store. On the final screen, set **Generate app bundle** to *Never*, and click **Create** to complete the signing configuration.

Build and test the Packaging Project in Release Mode

To avoid complications from Debug mode dependencies, set the Build configuration to Release mode, and build the Packaging Project.

Building the Packaging Project produces a **PackageWithExternalLocation** folder in the build output. That folder contains the `MSIX` file representing the identity package, as well as `Install` and `Remove` PowerShell scripts to register and unregister the generated identity package locally for testing.

The `Install` PowerShell script registers the generated identity package locally, and connects it with the `ExternalLocation` sibling folder for testing purposes. To test the application with identity, run the application executable from the `ExternalLocation` folder.

To associate identity with your application in production, you'll need to ship the generated identity package with your application, and register it in your installer.

Register the identity package in your installer

The last step to associate identity with your application is to register the identity package in your installer, and associate it with your application's installation directory.

The code listing below demonstrates registering the identity package by using the PackageManager.AddPackageByUriAsync method.

C#

```
using Windows.Management.Deployment;

...

var externalUri = new Uri(externalLocation);
var packageUri = new Uri(packagePath);

var packageManager = new PackageManager();

var options = new AddPackageOptions();
options.ExternalLocationUri = externalUri;

await packageManager.AddPackageByUriAsync(packageUri, options);
```

Be aware of the following important details about this code:

- Set `externalLocation` to the absolute path of your application's installation directory (without any executable names).
- Set `packagePath` to the absolute path of the identity package produced in the previous step (with the file name).

For production-ready code in C# and C++, see Sample apps below. The samples also demonstrate how to unregister the identity package on uninstall.

Sample apps

For fully functional C# and C++ apps that demonstrate how to register an identity package, see the PackageWithExternalLocation samples.

Optional steps

Localization

Some features that understand package identity might result in strings from your identity package manifest being displayed in the Windows OS. For example:

- An application that uses camera, microphone, or location APIs will have a dedicated control toggle in Windows Privacy Settings along with a brokered consent prompt that users can use to grant or deny access to those sensitive resources.
- An application that registers a share target will show up in the share dialog.

To localize the strings in the identity package manifest, see Localize the manifest.

Grant package identity by packaging with external location

Article • 04/07/2025

Many Windows features can be used by a desktop app only if that app has package identity at runtime. See Features that require package identity. If you have an existing desktop app, with its own installer, there's very little you need to change in order to benefit from package identity.

Starting in Windows 10, version 2004, you can grant package identity to an app simply by building and registering a *package with external location* with your app. Packaging with external location allows you to register a simple identity package in your existing installer without changing how or where you install your application. If you're familiar with full MSIX packaging, this is a much lighter-weight option as described below.

To build and register an identity package, follow these steps:

1. Create a package manifest for the identity package
2. Build and sign the identity package
3. Add identity metadata to your desktop application manifest
4. Register the identity package in your installer

Create a package manifest for the identity package

The first step to creating an identity package is to create a package manifest based on the below template. This is an MSIX manifest but is only used for identity and doesn't alter the app's runtime behavior.

XML

```
<?xml version="1.0" encoding="utf-8"?>
<Package IgnorableNamespaces="uap uap10"
  xmlns="http://schemas.microsoft.com/appx/manifest/foundation/windows10"
  xmlns:uap="http://schemas.microsoft.com/appx/manifest/uap/windows10"
  xmlns:uap10="http://schemas.microsoft.com/appx/manifest/uap/windows10/10"

xmlns:rescap="http://schemas.microsoft.com/appx/manifest/foundation/windows1
0/restrictedcapabilities">
  <Identity Name="ContosoPhotoStore" Publisher="CN=Contoso"
Version="1.0.0.0" ProcessorArchitecture="neutral" />
  <Properties>
    <DisplayName>Contoso PhotoStore</DisplayName>
```

```
    <PublisherDisplayName>Contoso</PublisherDisplayName>
    <Logo>Assets\storelogo.png</Logo>
    <uap10:AllowExternalContent>true</uap10:AllowExternalContent>
  </Properties>
  <Resources>
    <Resource Language="en-us" />
  </Resources>
  <Dependencies>
    <TargetDeviceFamily Name="Windows.Desktop" MinVersion="10.0.19041.0"
MaxVersionTested="10.0.26100.0" />
  </Dependencies>
  <Capabilities>
    <rescap:Capability Name="runFullTrust" />
    <rescap:Capability Name="unvirtualizedResources"/>
  </Capabilities>
  <Applications>
    <Application Id="ContosoPhotoStore" Executable="ContosoPhotoStore.exe"
uap10:TrustLevel="mediumIL" uap10:RuntimeBehavior="win32App">
      <uap:VisualElements AppListEntry="none" DisplayName="Contoso
PhotoStore" Description="Contoso PhotoStore App"
BackgroundColor="transparent"
Square150x150Logo="Assets\Square150x150Logo.png"
Square44x44Logo="Assets\Square44x44Logo.png" />
    </Application>
  </Applications>
</Package>
```

Note the below important details about this manifest:

- Fill in the `Identity` element attributes with the details of your application
  - `Publisher` must match the `Subject` of the certificate used to sign the application
- Fill in the `DisplayName` and `PublisherDisplayName` elements with the details of your application
  - Unless you add additional features to the manifest beyond simple identity, these values are not displayed anywhere
- Update the `Logo` element to a relative path within your application's installation directory that will resolve to a .png, .jpg, or .jpeg image
- Ensure the `AllowExternalContent` element is set to `true` as shown which enables reusing your existing installer
- Set `TargetDeviceFamily` `MinVersion` and `MaxVersionTested` per below:
  - Set `MinVersion` to `10.0.19041.0` as shown for maximum reach and uniformity across Windows 10 and Windows 11 OS versions
  - Set `MinVersion` to `10.0.26100.0` to restrict the identity package to Windows 11, version 24H2 and above
  - Set `MaxVersionTested` to `10.0.26100.0` as shown

- Ensure the `runFullTrust` and `unvirtualizedResources` capabilities are declared as shown for Win32 compatibility
- Add an `Application` element as shown for each binary associated with your application
  - Ensure `TrustLevel` is `mediumIL` and `RuntimeBehavior` is `win32App` as shown for Win32 compatibility
- The `VisualElements` child element is required, but the `AppListEntry="none"` attribute ensures the identity package isn't shown among installed apps
  - Update the `DisplayName` and `Description` attributes with relevant details and leave the other attributes as shown (the referenced image paths do not need to resolve)

The identity package created from this manifest will be connected to your application's installation directory when you register the package in a later step.

Build and sign the identity package

After you create your identity package manifest, build the identity package using the MakeAppx.exe tool in the Windows SDK.

Console

```
MakeAppx.exe pack /o /d <path to directory that contains manifest> /nv /p
<output path>\MyPackage.msix
```

Note: The `/nv` flag is required to bypass validation of referenced file paths in the manifest.

In order to be installed on end user computers, the identity package must be signed with a certificate that is trusted on the target computer. You can create a new self-signed certificate for development purposes and sign your identity package using SignTool, which is available in the Windows SDK, but a production certificate from an IT Department or a service like Azure Trusted Signing will be required to register the package on end user computers.

Console

```
SignTool.exe sign /fd SHA256 /a /f <path to certificate>\MyCertificate.pfx
/p <certificate password> <path to package with external
location>\MyPackage.msix
```

Note: For how to build and sign the identity package within a CI/CD pipeline with production certificates, see the MSIX and CI/CD Pipeline Overview for examples.

Add identity metadata to your desktop application manifest

You connect the identity package with your application executables by including application manifests (a.k.a side-by-side or fusion manifests) with metadata that matches metadata from the identity package manifest.

Below is an example application manifest snippet demonstrating the `msix` element required to connect your binaries with metadata from your identity package.

XML

```xml
<?xml version="1.0" encoding="utf-8"?>
<assembly manifestVersion="1.0" xmlns="urn:schemas-microsoft-com:asm.v1">
  <assemblyIdentity version="0.0.0.0" name="ContosoPhotoStore"/>
  <msix xmlns="urn:schemas-microsoft-com:msix.v1"
          publisher="CN=Contoso"
          packageName="ContosoPhotoStore"
          applicationId="ContosoPhotoStore"
        />
</assembly>
```

The attributes of the `msix` element must match these values from the identity package manifest:

- The `packageName` and `publisher` attributes must match the `Name` and `Publisher` attributes in the Identity element in your identity package manifest, respectively
- The `applicationId` attribute must match the `Id` attribute of the corresponding Application element in your identity package manifest

Register the identity package in your installer

The last step to associate identity with your application is to register the identity package in your installer and associate it with your application's installation directory.

The below snippet demonstrates using the PackageManager.AddPackageByUriAsync method to register the identity package.

C#

```
using Windows.Management.Deployment;

...

var externalUri = new Uri(externalLocation);
var packageUri = new Uri(packagePath);

var packageManager = new PackageManager();

var options = new AddPackageOptions();
options.ExternalLocationUri = externalUri;

await packageManager.AddPackageByUriAsync(packageUri, options);
```

Note the below important details about this code:

- Set `externalLocation` to the absolute path of your application's installation directory (without any executable names)
- Set `packagePath` to the absolute path of the identity package produced in the previous step (with the file name)

For a complete example including unregistering the package on uninstall, see StartUp.cs.

Sample app

See the SparsePackages sample for a fully functional sample app that demonstrates how to grant package identity to a desktop app by registering an identity package.

Deployment overview

Article • 10/14/2023

The topics in this section introduce options and guidance around deploying different types of Windows apps.

Advantages and disadvantages of packaging your app

Your first decision will be whether or not to package your app.

- **Packaged app**. Packaged apps are the only kind that have *package identity* at runtime. Package identity is needed for many Windows extensibility features—including background tasks, notifications, live tiles, custom context menu extensions, and share targets. That's because the operating system (OS) needs to be able to identify the caller of the corresponding API. See Features that require package identity.
  - Commonly, a packaged app's process runs inside a lightweight app container, and is isolated using file system and registry virtualization (see AppContainer for legacy apps and MSIX AppContainer apps). But you can configure a packaged app to *not* run in an app container.
  - A packaged app is packaged by using MSIX technology (see What is MSIX?).
  - **Packaged app with external location**. But because some existing apps aren't yet ready for all of their content to be present inside an MSIX package, there's an option for your app to be *packaged with external location*. That enables your app to have package identity; thereby being able to use those features that require it. For more info, see Grant package identity by packaging with external location.
  - A packaged app is *installed* by using MSIX, also. But if you choose to *package with external location*, then you can think of that as a "bring-your-own-installer" model. So there *will* be some installer work for you to do with that option. It's essentially a hybrid option between a packaged and an unpackaged app.
- **Unpackaged app**. You can opt out of using MSIX altogether by creating an unpackaged app. But be aware that an unpackaged app *doesn't* have package identity at runtime; so it misses out on certain Windows features (see Features that require package identity).

Each type of app can be published to the Microsoft Store, and installed that way or via Windows App Installer.

> **Important**
>
> We recommend that you package your app, and configure it to run in an app container. It'll be a seamless, modern, and reliable installation and update experience for your customers; and it'll be secure at runtime.

Expand table

	Packaged (and optionally running in an app container)	**Packaged with external location or unpackaged**
Advantages	Gives your users an easy way to install, uninstall, and update your app. Uninstall is clean—when your app is uninstalled, the system is restored to the same state it was in before installation—no artifacts are left behind. This kind of app also supports incremental and automatic updates. And the Microsoft Store optimizes for apps of this kind (although they can be used in or out of the Store). You get the benefits of having package identity.	With these options, your app is unrestricted in terms of the kind of app it is, the APIs it can call, and its access to the Registry and file system. Packaging with external location means that you get the benefits of having package identity.
Disadvantages	Your app is limited in terms of the kind of app it can be, and the agency it can have within the system. For example, an NT Service isn't possible. Inter-process communication (IPC) options are limited; privileged/elevated access is restricted if you're publishing to the Microsoft Store; file/Registry access is virtualized (but also see Flexible virtualization). And in some situations enterprise policies can disable updates by disabling the Microsoft Store.	With these options, an app that is at risk of causing stale configuration data and software to accumulate after the app has been uninstalled. That can be an issue for the customer and for the system. Your app will typically be installed and updated using `.exe` or `.msi` files, or via other installation and update solutions; using a custom installer, ClickOnce, or xcopy deployment. An unpackaged app lacks the benefits of having package identity.

For more info about package install location, working directory, and file and registry virtualization, see Understanding how packaged desktop apps run on Windows.

Use the Windows App SDK

After deciding whether or not to package your app, you can next decide whether or not to use the Windows App SDK in your app. See Windows App SDK deployment overview.

Win32 and .NET desktop apps

If you build a Win32 desktop app (sometimes called a *classic desktop app*) or a .NET app —including Windows Presentation Foundation (WPF) and Windows Forms (WinForms)— then you can package and deploy your app using MSIX.

- Create an MSIX package from an existing installer
- Build an MSIX package from source code
- Manage your MSIX deployment

You can also package and deploy these types of apps using other installation technologies.

Windows App SDK deployment overview

Article • 11/02/2023

There are two ways in which you can deploy the Windows App SDK:

- **Framework-dependent**. Your app depends on the Windows App SDK runtime and/or Framework package being present on the target machine. Framework-dependent deployment is the default deployment mode of the Windows App SDK for its efficient use of machine resources and serviceability.
- **Self-contained**. Your app carries the Windows App SDK dependencies with it. Self-contained deployment is a deployment option that was introduced in Windows App SDK 1.1 Preview 1.

This topic also uses the terms *packaged app*, *packaged app with external location*, and *unpackaged app*. For explanations of those terms, see the Deployment overview.

Expand table

	Deploy framework-dependent	Deploy self-contained
Advantages	*Small deployment*. Only your app and its other dependencies are distributed. The Windows App SDK runtime and Framework package are installed automatically by framework-dependent apps that are packaged; or as part of the Windows App SDK runtime installer by framework-dependent apps that are either packaged with external location or unpackaged. *Serviceable*. Servicing updates to the Windows App SDK are installed automatically via the Windows App SDK Framework package without any action required of the app.	*Control Windows App SDK version*. You control which version of the Windows App SDK is deployed with your app. Servicing updates of the Windows App SDK won't impact your app unless you rebuild and redistribute it. *Isolated from other apps*. Apps and users can't uninstall your Windows App SDK dependency without uninstalling your entire app. *Xcopy deployment*. Since the Windows App SDK dependencies are carried by your app, you can deploy your app by simply xcopy-ing your build output, without any additional installation requirements.

	Deploy framework-dependent	Deploy self-contained
Disadvantages	*Additional installation dependencies*. Requires installation of the Windows App SDK runtime and/or Framework package, which can add complexity to app installation. *Shared dependencies*. Risk that shared dependencies are uninstalled. Apps or users uninstalling the shared components can impact the user experience of other apps that share the dependency. *Compatibility risk*. Risk that servicing updates to the Windows App SDK introduce breaking changes. While servicing updates should provide backward compatibility, it's possible that regressions are introduced.	*Larger deployments (unpackaged apps only)*. Because your app includes the Windows App SDK, the download size and hard drive space required are greater than would be the case for a framework-dependent version. *Performance (unpackaged apps only)*. Slower to load, and uses more memory since code pages aren't shared with other apps. *Not serviceable*. The Windows App SDK version distributed with your app can be updated only by releasing a new version of your app. You're responsible for integrating servicing updates of the Windows App SDK into your app.

Also see Create your first WinUI 3 project, and Use the Windows App SDK in an existing project.

More info about framework-dependent deployment

Before configuring your framework-dependent app for deployment, to learn more about the dependencies your app takes when it uses the Windows App SDK, review Deployment architecture for the Windows App SDK.

Packaged apps

If you've chosen to go with a framework-dependent packaged app (see Deployment overview), then here are instructions on how to deploy the Windows App SDK runtime with the app:

- Windows App SDK deployment guide for framework-dependent packaged apps
- Manage your MSIX deployment

Packaged with external location or unpackaged apps

If you've chosen to go with a framework-dependent packaged app with external location, or a framework-dependent unpackaged app (see Deployment overview), then here are instructions on how to deploy the Windows App SDK runtime with the app:

- Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged
- Tutorial: Use the bootstrapper API in an app packaged with external location or unpackaged that uses the Windows App SDK

More info about self-contained deployment

See Windows App SDK deployment guide for self-contained apps.

Initialize the Windows App SDK

The way that you should initialize the Windows App SDK depends on whether, and how, you package your app; and on the way in which you deploy relative to the Windows App SDK runtime. Use the section below that applies to your app.

Packaged apps

Expand table

How your app deploys	How to initialize
Framework-dependent	See Call the Deployment API.
Self-contained	No initialization necessary.

Unpackaged apps, and apps packaged with external location

Expand table

How your app deploys	How to initialize
Framework-dependent	See Use the bootstrapper API in an app packaged with external location or unpackaged.
Self-contained	See Opting out of (or into) automatic UndockedRegFreeWinRT support.

Deployment architecture and overview for framework-dependent apps

Article • 04/19/2023

This article explains a high-level architecture of Windows App SDK deployment. The concepts below apply primarily to Windows App SDK framework-dependent apps. A framework-dependent app depends on the Windows App SDK runtime being present on the target machine.

There are two main options to distribute a framework-dependent app:

Expand table

App deployment method	Requirements
Packaged	- Must declare dependency on Framework package in the package manifest. - Deployment API is required for Microsoft Store distributed apps and recommended for non-Store distributed apps to ensure runtime dependencies are installed.
Packaged with external location or unpackaged	- Must distribute runtime either using the Installer or by installing required MSIX packages directly. - Additional runtime requirements: Must initialize access to the Windows App SDK runtime via the Bootstrap API.

For more details on these requirements, see the following articles:

- Windows App SDK deployment guide for framework-dependent packaged apps
- Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged

Key terms

The following sections define key terms for Windows App SDK deployment and additional details on some of these packages.

Expand table

Term	Definition
Windows App SDK runtime	The MSIX packages required by an app to use the Windows App SDK. These packages include: Framework, Main, Singleton, and DDLM.

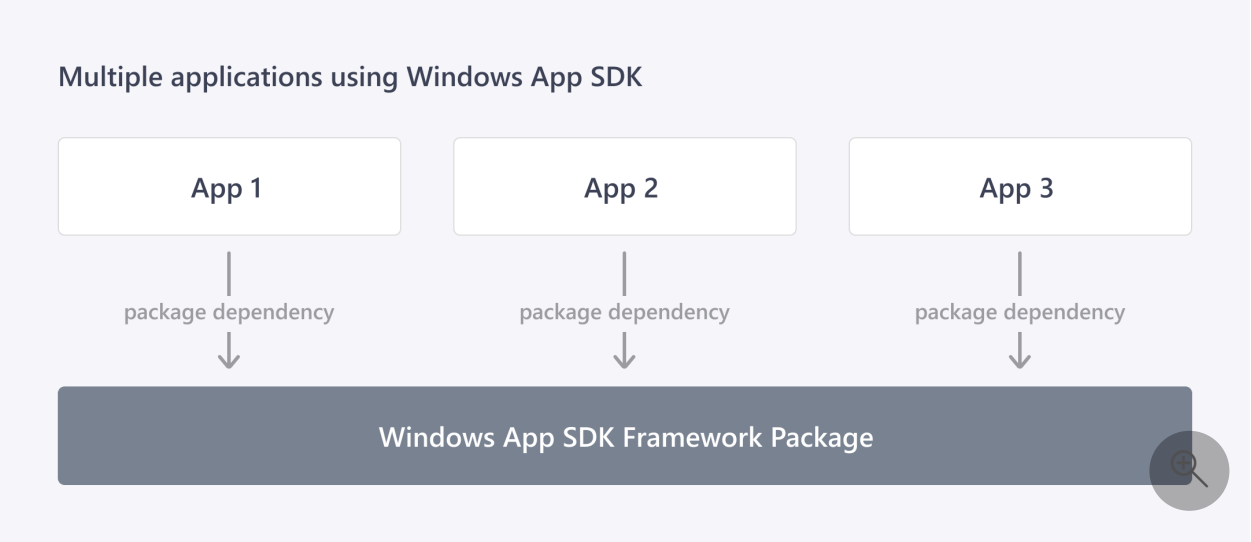
Term	Definition
	Depending on the features used and your app deployment method, you will need a certain set of these packages on the target machine.
Framework package	Contains binaries used at run time by apps (most Windows App SDK features). The framework includes a bootstrapper component that enables apps to automatically install the latest version of the Windows App SDK, which will be updated on a regular release cadence.
Main package	Package that contains background tasks to keep track of dynamic dependencies, and enables automatic updates to the Framework package from the Microsoft Store.
Singleton package	Contains background tasks, services, app extensions, and other components not included in the Framework package such as Push Notifications. This is generally a single long-running process that is brokered between apps.
Dynamic Dependency Lifetime Manager (DDLM) package	Prevents the OS from performing servicing updates to the MSIX packages while a packaged with external location or unpackaged app is in use.
Bootstrapper	An app-local binary used by packaged with external location and unpackaged apps to locate and load the best Windows App SDK version match as needed by the app.
Provisioning	The process of installing and registering packages (including files and registry keys) system-wide to eliminate the need for repeated installation by the other users. It can be done either as part of the OS or done during installation of an app.
Installer	Refers to the .exe installer which deploys the Framework, Main, Singleton, and DDLM packages.
MSIX	Modern installer technology that enables users to safely install an app per user, directly from the Microsoft Store or a web site. On Enterprise or shared PCs, apps can be installed for all users via PowerShell and MDM.

Framework package

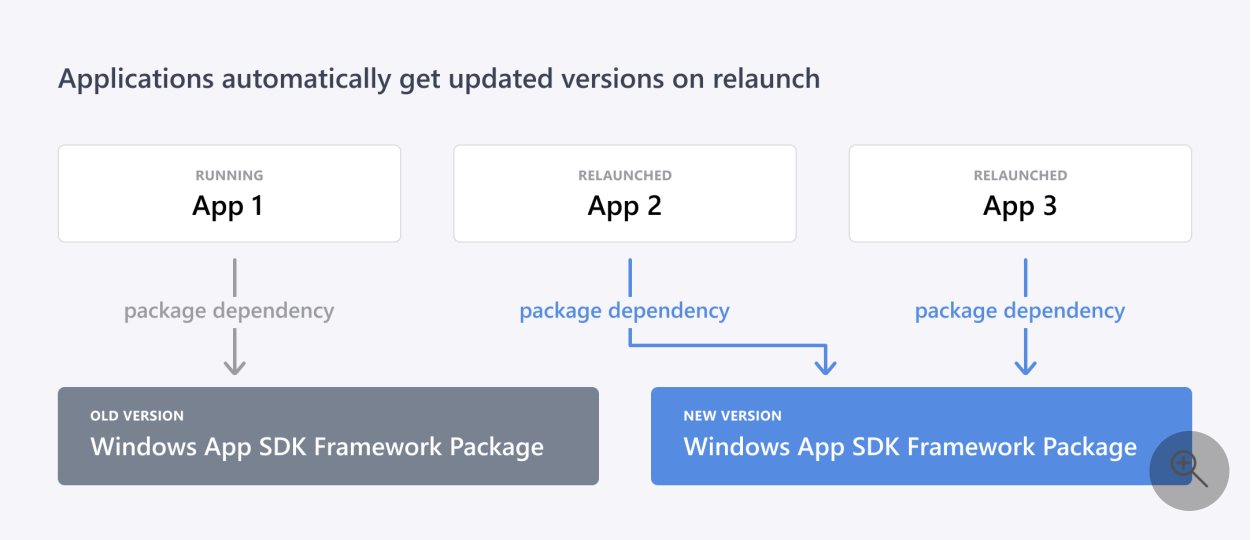
When you build an app that uses the Windows App SDK, your app references a set of Windows App SDK runtime components that are distributed to end users via a *framework package*. The framework package allows apps to access Windows App SDK components through a single shared source on the user's device, instead of bundling them into the app package. The framework package also carries its own resources, such as DLLs and API definitions (COM and Windows Runtime registrations). These resources

run in the context of your app, so they inherit the capabilities and privileges of your app, and don't assert any capabilities or privileges of their own. For more information about framework package dependencies, see MSIX framework packages and dynamic dependencies.

The Windows App SDK framework package is an MSIX package that is deployed to end users through the Microsoft Store. It can be easily and quickly updated with servicing releases, which may include security and reliability fixes. All framework-dependent apps that use the Windows App SDK have a dependency on a shared instance of the framework package, as illustrated in the following diagram.



When a new version of the Windows App SDK framework package is serviced, all framework-dependent apps are updated to the new version without themselves having to redistribute a copy. Windows updates to the newest version of frameworks as they are released, and apps will automatically reference the latest framework package version during relaunch. Older framework package versions will not be removed from the system until they are no longer running or being actively used by apps on the system.



Because app compatibility is important to Microsoft and to apps that depend on the Windows App SDK, the Windows App SDK framework package follows Semantic Versioning 2.0.0 rules. This means that after we release version 1.0 of the Windows App SDK, the Windows App SDK framework package will guarantee compatibility between minor and patch version changes, and breaking changes will occur only between major version updates.

Singleton package

The **singleton package** ensures that a single long-running process can handle services that are used across multiple apps, which may be running on different versions of the Windows App SDK.

The Windows App SDK singleton is needed to enable push notifications for unpackaged apps and packaged Win32 applications using Windows versions below 20H1, which cannot be supported by the existing UWP PushNotificationTrigger and ToastNotificationActionTrigger class. Future Windows App SDK features that cannot be supported by the Framework package will be added to the Singleton package.

Additional requirements for unpackaged apps

Bootstrapper

The bootstrapper is a library that must be included with your packaged with external location or unpackaged app. It provides the bootstrapper API (see Use the Windows App SDK runtime for apps packaged with external location or unpackaged), which enables unpackaged apps to perform these important tasks:

- Initialize the Dynamic Dependency Lifetime Manager (DDLM) for the Windows App SDK framework package.
- Find and load the Windows App SDK framework package to the app's package graph.

To accomplish these tasks, the nuget package leverages module initializers to wire up the bootstrapper for you. Simply set `<WindowsPackageType>None</WindowsPackageType>` in your project file. In advanced scenarios, if you want control over the initialization, you can call the bootstrapper API directly in your app's startup code (see Tutorial: Use the bootstrapper API in an app packaged with external location or unpackaged that uses the Windows App SDK) so that it can properly initialize the system for the unpackaged app. Your app must use the bootstrapper API before it can use Windows App SDK features such as WinUI, App lifecycle, MRT Core, and DWriteCore.

The bootstrapper library in the Windows App SDK 1.0 release includes:

- **Microsoft.WindowsAppRuntime.Bootstrap.dll** (C++ and C#)
- **Microsoft.WindowsAppRuntime.Bootstrap.Net.dll** (C# wrapper)

Dynamic Dependency Lifetime Manager (DDLM)

The purpose of the DDLM is to prevent servicing of the Windows App SDK framework package while it is in use by an unpackaged app. It contains a server that must be initialized by the bootstrapper early in an app's startup to provide that functionality.

There is one DDLM for each version and architecture of the Windows App SDK framework package. This means on an `x64` computer, you may have both an `x86` and an `x64` version of the DDLM to support apps of both architectures.

Additional requirements

- For packaged apps, the VCLibs framework package dependency is a requirement. For more info, see C++ Runtime framework packages for Desktop Bridge.
- For unpackaged apps, the Visual C++ Redistributable is a requirement. For more info, see Microsoft Visual C++ Redistributable latest supported downloads.
- **C#**. For the .NET runtime, see Download .NET.

Windows App SDK deployment guide for framework-dependent packaged apps

Article • 08/19/2024

This article provides guidance about deploying framework-dependent packaged apps (see What is MSIX?) that use the Windows App SDK. The equivalent topic for other framework-dependent packaging options is Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged.

Overview

By default, when you create a project using one of the WinUI 3 templates in Visual Studio, your project is configured to build the app into an MSIX package using either single-project MSIX (see Package your app using single-project MSIX) or a Windows Application Packaging project (see Set up your desktop application for MSIX packaging in Visual Studio). You can then build an MSIX package for your app by using the instructions in Package a desktop or UWP app in Visual Studio. After you build an MSIX package for your app, you have several options to Manage your MSIX deployment.

To learn more about the packages that your packaged app might need when it uses the Windows App SDK, see Deployment architecture for the Windows App SDK. Those include the *Framework*, *Main*, and *Singleton* packages; which are all signed and published by Microsoft. There are two main requirements for deploying a packaged app:

1. Deploy the Windows App SDK framework package.
2. Call the Deployment API.

Prerequisites

- For packaged apps, the VCLibs framework package dependency is a requirement. For more info, see C++ Runtime framework packages for Desktop Bridge.
- **C#**. .NET 6 or later is required. For more info, see .NET Downloads.

Deploy the Windows App SDK framework package

The Windows App SDK framework package contains the Windows App SDK binaries used at run time, and it is installed with your application. The framework has different deployment requirements for different channels of the Windows App SDK.

Stable version

When you install a stable release version (see Stable channel release notes) of the Windows App SDK NuGet package on your development computer, and you create a project using one of the provided WinUI 3 project templates, the generated package manifest contains a PackageDependency element that specifies a dependency on the framework package.

However, if you build your app package manually using a separate Windows Application Packaging Project, then you must declare a **PackageReference** in your `Application (package).wapproj` file, like the following:

```xml
<ItemGroup>
   <PackageReference Include="Microsoft.WindowsAppSDK" Version="1.0.1">
       <IncludeAssets>build</IncludeAssets>
   </PackageReference>
</ItemGroup>
```

That package dependency ensures that the Framework package is installed when your app is deployed to another computer.

Preview version

When you install a preview release version (see Preview channel release notes) of the Windows App SDK NuGet package on your development computer, a preview version of the Windows App SDK framework package is deployed during build time as a NuGet package dependency.

Call the Deployment API

Also see Initialize the Windows App SDK.

The Deployment API is provided by the Windows App SDK framework package, and is available in the Microsoft.Windows.ApplicationModel.WindowsAppRuntime namespace. The Windows application model doesn't support declaring a dependency on the Main and Singleton packages. The Deployment API is therefore required for these reasons:

1. To deploy the Singleton package for features not in the Framework package (for example, push notifications).
2. To deploy the Main package, which enables automatic updates to the Framework package from the Microsoft Store.

For packaged apps that are *not* distributed through the Store, you as the developer are responsible for distributing the Framework package. We recommended that you call the Deployment API so that any critical servicing updates are delivered. Note that for using features outside the Framework package (for example, push notifications), the Singleton package must be deployed (this can be done with the Deployment API, or by redistributing the MSIX packages using your own install method).

> **ⓘ Important**
>
> In Windows App SDK version 1.0, only packaged apps that are full trust or that have the **packageManagement** restricted capability have the permission to use the Deployment API to install the Main and Singleton package dependencies. Support for partial trust packaged apps will be coming in later releases.

You should call the Deployment API after your app's process is initialized, but before your app uses Windows App SDK runtime features that use the Singleton package (for example, push notifications). The main methods of the Deployment API are the static GetStatus and Initialize methods of the DeploymentManager class.

- The **GetStatus** method returns the current deployment status of the Windows App SDK runtime that's currently loaded. Use this method to identify whether there's work required to install Windows App SDK runtime packages before the current app can use Windows App SDK features.
- The **Initialize** method verifies whether all required packages are present to a minimum version needed by the Windows App SDK runtime that's currently loaded. If any package dependencies are missing, then the method attempts to register those missing packages. Beginning in Windows App SDK 1.1, the **Initialize** method also supports the option to force-deploy the Windows App SDK runtime packages. That shuts down any processes for the *Main* and *Singleton* runtime packages, and thus interrupts their services (for example, push notifications won't deliver notifications during this time).

Deployment API sample app

For additional guidance on how to use the **GetStatus** and **Initialize** methods of the **DeploymentManager** class, explore the available sample app.

Explore Deployment API sample app

Address installation errors

If the Deployment API encounters an error during installation of the Windows App SDK runtime packages, it returns an error code that describes the problem.

For example, if your app is not full trust, or doesn't have the packageManagement restricted capability, then you'll get an **ACCESS_DENIED** error code. To review other error codes that you may encounter and their possible causes, see Troubleshooting packaging, deployment, and query of Windows apps.

If the error code doesn't provide enough information, then you can find more diagnostic information in the detailed event logs (see Get diagnostic information).

If you encounter errors that you can't diagnose, then file an issue in the WindowsAppSDK GitHub repo with the error code and event logs so that we can investigate the issue.

Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged

Article • 08/07/2024

This topic provides guidance about deploying apps that are packaged with external location, or are unpackaged, and that use the Windows App SDK.

- Such apps are desktop apps (not UWP apps).
- They can be written in a .NET language such as C#, or in C++.
- For their user-interface, they can use WinUI 3, or WPF, or WinForms, or another UI framework.

Overview

Developers of packaged with external location and unpackaged apps are responsible for deploying required Windows App SDK runtime packages to their end users. This can be done either by running the installer or by installing the MSIX packages directly. These options are described in more detail in the Deploy Windows App SDK runtime section below.

Packaged with external location and unpackaged apps also have extra runtime requirements. You must initialize access to the Windows App SDK runtime using the Bootstrapper API. In addition, the Dynamic Dependencies API can be used if your app makes use of other framework packages aside from the Windows App SDK. These requirements are described in more detail in the Runtime requirements for apps packaged with external location or unpackaged section below.

Prerequisites

- Download the latest installer & MSIX packages.
- For apps that are packaged with external location or unpackaged, the Visual C++ Redistributable is a requirement. For more info, see Microsoft Visual C++ Redistributable latest supported downloads.
- **C#**. .NET 6 or later is required. For more info, see .NET Downloads.

Additional prerequisites

- Experimental and preview versions of the Windows App SDK require that sideloading is enabled to install the runtime.
    - Sideloading is automatically enabled on Windows 10 version 2004 and later.
    - If your development computer or the deployment computer is running **Windows 11**, confirm whether sideloading is enabled:
        - **Settings** > **Privacy & security** > **For developers**. Make sure the **Developer mode** setting is turned on.
    - If your development computer or the deployment computer is running **Windows 10 version 1909 or an earlier version**, confirm whether sideloading is enabled:
        - **Settings** > **Update & Security** > **For developers** > **Use developer features**. Confirm that **Sideload apps** or **Developer mode** is selected.
    - The **Developer mode** setting includes sideloading as well as other features.

      > **Note**
      >
      > If the computer is managed in an enterprise environment, there might be a policy preventing these settings from being changed. In that case if you get an error when you or your app tries to install the Windows App SDK runtime, contact your IT Professional to enable sideloading or **Developer mode**.

Deploy Windows App SDK runtime

Packaged with external location and unpackaged apps have two options to deploy the Windows App SDK runtime:

- **Option 1: Use the Installer**: The silent installer distributes all Windows App SDK MSIX packages. A separate installer is available for each of the `X64`, `X86` and `Arm64` architectures.
- **Option 2: Install the packages directly**: You can have your existing setup or MSI tool carry and install the MSIX packages for the Windows App SDK.

Option 1: Use the Installer

You can deploy all Windows App SDK runtime packages by running the installer. The installer is available at Downloads for the Windows App SDK. When running the installer (.exe), you should see an output similar to the following:

Console

```
Deploying package:
Microsoft.WindowsAppRuntime.1.0_0.318.928.0_x64__8wekyb3d8bbwe
Package deployment result : 0x0

Deploying package:
Microsoft.WindowsAppRuntime.1.0_0.318.928.0_x86__8wekyb3d8bbwe
Package deployment result : 0x0

Deploying package:
MicrosoftCorporationII.WindowsAppRuntime.Main.1.0_0.318.928.0_x64__8wekyb3d8
bbwe
Package deployment result : 0x0
Provisioning result : 0x0

Deploying package:
Microsoft.WindowsAppRuntime.Singleton_0.318.928.0_x64__8wekyb3d8bbwe
Package deployment result : 0x0
Provisioning result : 0x0

Deploying package: Microsoft.WinAppRuntime.DDLM.0.318.928.0-
x6_0.318.928.0_x64__8wekyb3d8bbwe
Package deployment result : 0x0
Provisioning result : 0x0

Deploying package: Microsoft.WinAppRuntime.DDLM.0.318.928.0-
x8_0.318.928.0_x86__8wekyb3d8bbwe
Package deployment result : 0x0
Provisioning result : 0x0

All install operations successful.
```

You can run the installer with no user interaction and suppress all text output with the `--quiet` option:

Console

```
WindowsAppRuntimeInstall.exe --quiet
```

You can also choose to force update the MSIX packages and shutdown any currently running Windows App SDK processes using the `--force` option. This feature is introduced in 1.1.

Console

```
WindowsAppRuntimeInstall.exe --force
```

To see all installer command line options, run `WindowsAppRuntimeInstall --h`.

After the installation is complete, you can run your packaged with external location or unpackaged app. For an example of how to build and run a packaged with external location or unpackaged app that uses the Windows App SDK, see Tutorial: Use the bootstrapper API in an app packaged with external location or unpackaged that uses the Windows App SDK.

Chain the Windows App SDK installer to your app's setup

If you have a custom setup program for your app, you can chain the Windows App SDK setup process in your app's setup process. The Windows App SDK installer currently does not provide a default UI so you will need to chain by using your setup's custom UI.

You can silently launch and track the Windows App SDK setup while showing your own view of the setup progress by using ShellExecute. The Windows App SDK installer silently unpacks the Windows App MSIX bundle and calls the PackageManager.AddPackageAsync method to complete the installation. This is very similar to other runtime installers you may have used, like .NET, Visual C++, or DirectX.

For a code example that demonstrates how to run the Windows App SDK installer from your setup program, see the **RunInstaller** function in the installer functional tests.

Installer sample

See the sample below to see how to launch the installer from a Win32 setup program without popping up a console window during setup:

Explore Installer sample

Troubleshooting

Return codes

The following table lists the most common return codes for the Windows App SDK .exe installer. The return codes are the same for all versions of the installer.

Expand table

Return code	Description
0x0	Package installation or provisioning was completed successfully.
0x80073d06	One or more packages failed to install.
0x80070005	System-wide install or provisioning was not possible because the app is not running elevated or the user doing the installation doesn't have admin privileges.

Installation errors

If the Windows App SDK installer returns an error during installation, it will return an error code that describes the problem.

- See the list of common error codes.
- If the error code doesn't provide enough information, you can find more diagnostic information in the detailed event logs.
- Please file an issue with the error code and event logs so the issue can be investigated.

Option 2: Deploy Windows App SDK runtime packages directly

As an alternative to using the Windows App SDK installer for deployment to end users, you can manually deploy the MSIX packages through your app's program or MSI. This option can be best for developers who want more control.

For an example that demonstrates how your setup program can install the MSIX packages, see install.cpp in the Windows App SDK installer code.

To check whether the Windows App SDK is installed already (and, if so, what version), you can check for specific package families by calling PackageManager.FindPackagesForUserWithPackageTypes.

From a *mediumIL* (full trust) unpackaged process (see Application element), you can use the following code to check for a package registered to the current user:

C#

```
using Windows.Management.Deployment;

public class WindowsAppSDKRuntime
{
    public static IsPackageRegisteredForCurrentUser(
        string packageFamilyName,
```

```
        PackageVersion minVersion,
        Windows.System.ProcessorArchitecture architecture,
        PackageTypes packageType)
    {
        ulong minPackageVersion = ToVersion(minVersion);

        foreach (var p : PackageManager.FindPackagesForUserWithPackageTypes(
            string.Empty, packageFamilyName, packageType)
        {
            // Is the package architecture compatible?
            if (p.Id.Architecture != architecture)
            {
                continue;
            }

            // Is the package version sufficient for our needs?
            ulong packageVersion = ToVersion(p.Id.Version);
            if (packageVersion < minPackageVersion)
            {
                continue;
            }

            // Success.
            return true;
        }

        // No qualifying package found.
        return false;
    }

    private static ulong ToVersion(PackageVersion packageVersion)
    {
        return ((ulong)packageVersion.Major << 48) |
               ((ulong)packageVersion.Minor << 32) |
               ((ulong)packageVersion.Build << 16) |
               ((ulong)packageVersion.Revision);
    }
}
```

For the scenario above, calling **FindPackagesForUserWithPackageTypes** is preferable to calling **FindPackagesForUser**. That's because you can narrow the search to (for this example), just *framework* or main *packages*. And that avoids matching other types of packages (such as *resource*, *optional*, or *bundle*) which aren't of interest for this example.

To use the current/calling user context, set the *userSecurityId* parameter is to an empty string.

And now some info to help you decide *how* to call the function in the code example above. A properly installed runtime is composed of multiple packages that depend on the system's CPU architecture:

- On an x86 machine: Fwk=[x86], Main=[x86], Singleton=[x86], DDLM=[x86].
- On an x64 machine: Fwk=[x86, x64], Main=[x64], Singleton=[x64], DDLM=[x86, x64].
- On an arm64 machine: Fwk=[x86, x64, arm64], Main=[arm64], Singleton=[arm64], DDLM=[x86, x64, arm64].

For the *Main* and *Singleton* packages, their architecture should match the system's CPU architecture; for example, x64 packages on an x64 system. For the *Framework* package, an x64 system can run both x64 and x86 apps; similarly an arm64 system can run arm64, x64, and x86 apps. A *DDLM* package check is similar to a *Framework* check, except that `PackageType=main`, and the *packagefamilyname* differs, and more than one (different) *packagefamilyname* could be applicable, due to *DDLM*'s unique naming scheme. For more info, see the MSIX packages spec. So the checks are more like this:

C#

```
public static bool IsRuntimeRegisteredForCurrentUser(PackageVersion
minVersion)
{
    ProcessorArchitecture systemArchitecture = DetectSystemArchitecture();

    return IsFrameworkRegistered(systemArchitecture, minVersion) &&
           IsMainRegistered(systemArchitecture, minVersion) &&
           IsSingletonRegistered(systemArchitecture, minVersion) &&
           IsDDLMRegistered(systemArchitecture, minVersion);
}

private static ProcecssorArchitecture DetectSystemArchitecture()
{
    // ...see the call to IsWow64Process2(), and how the result is used...
    // ...as per `IsPackageApplicable()` in
    // [install.cpp]
(https://github.com/microsoft/WindowsAppSDK/blob/main/installer/dev/install.
cpp)
    // line 99-116...
    // ...WARNING: Use IsWow64Process2 to detect the system architecture....
    // ...         Other similar APIs exist, but don't give reliably
accurate results...
}

private static bool IsFrameworkRegistered(ProcessorArchitecture
systemArchitecture,
    PackageVersion minVersion)
{
    // Check x86.
    if (!IsPackageRegisteredForCurrentUser(

global::Microsoft.WindowsAppSDK.Runtime.Packages.Framework.PackageFamilyName
,
        minVersion, ProcessorArchitecture.X86,
```

```
        PackageTypes.Framework))
    {
        return false;
    }

    // Check x64 (if necessary).
    if ((systemArchitecture == ProcessorArchitecture.X64) ||
        (systemArchitecture == ProcessorArchitcture.Arm64))
    {
        if (!IsPackageRegisteredForCurrentUser(

global::Microsoft.WindowsAppSDK.Runtime.Packages.Framework.PackageFamilyName
,
            minVersion, ProcessorArchitecture.X64,
            PackageTypes.Framework))
        {
            return false;
        }
    }

    // Check arm64 (if necessary).
    if (systemArchitecture == ProcessorArchitcture.Arm64)
    {
        if (!IsPackageRegisteredForCurrentUser(

global::Microsoft.WindowsAppSDK.Runtime.Packages.Framework.PackageFamilyName
,
            minVersion, ProcessorArchitecture.Arm64,
            PackageTypes.Framework))
        {
            return false;
        }
    }

    return true;
}

private static bool IsMainRegistered(ProcessorArchitecture
systemArchitecture,
    PackageVersion minVersion)
{
    return IsPackageRegisteredForCurrentUser(

global::Microsoft.WindowsAppSDK.Runtime.Packages.Main.PackageFamilyName,
        minVersion,
        systemArchitecture,
        PackageTypes.Main);
}

private static bool IsSingletonRegistered(ProcessorArchitecture
systemArchitecture,
    PackageVersion minVersion)
{
    return IsPackageRegisteredForCurrentUser(
```

```
global::Microsoft.WindowsAppSDK.Runtime.Packages.Singleton.PackageFamilyName
,
        minVersion,
        systemArchitecture,
        PackageTypes.Main);
}

private static bool IsDDLMRegistered(ProcessorArchitecture
systemArchitecture,
    PackageVersion minVersion)
{
    // ...similar to IsFrameworkRegistered, but the packageFamilyName is
more complicated...
    // ...and no predefined constant is currently available...
    // ...for more details, see
    //
https://github.com/microsoft/WindowsAppSDK/blob/main/specs/Deployment/MSIXPa
ckages.md.
}
```

The info and code above covers the basic detection scenario. To detect whether the runtime is provisioned for all users, or to do the above from an App Container, and/or do it from a packaged `mediumIL` process, additional logic is needed.

Deployment scenarios

- **Installing the Windows App SDK Runtime system-wide**: System-wide install alters the machine for all users, including new users that are added in the future. If the app is running elevated and the user doing the installation has admin privileges, then the installer will register the MSIX packages system-wide by calling the ProvisionPackageForAllUsersAsync. If system-wide registration is not successful, the installation will be performed for the current user doing the installation only. In a managed Enterprise environment, the IT admin should be able to provision for everyone as usual.

- **Architectures redistributed by the Windows App SDK installer**: The Windows App SDK installer is available in the `x86`, `x64`, and `Arm64` architectures. Each version of the installer includes the MSIX packages for just the specific architecture it's named for. For example, if you run the `x86` `WindowsAppRuntimeInstall.exe` on an x64 or and Arm64 device, then that `x86` installer will deploy onto that device only the packages for the x86 architecture.

- **All Windows App SDK MSIX packages are already installed on the computer**: MSIX packages are installed to a system-wide location with only one copy on disk. If an app attempts installation of the Windows App SDK when all the MSIX

package dependencies are already installed on the machine, then the installation is not performed.

- **One or more of the Windows App SDK MSIX packages are not installed on the computer**: When deploying the Windows App SDK, always attempt to install all the MSIX packages (framework, main, singleton, DDLM) to ensure that all dependencies are installed and you avoid disruption to the end-user experience.

Runtime requirements for apps packaged with external location or unpackaged

Apps that are packaged with external location or unpackaged have extra runtime requirements to use the Windows App SDK runtime. This involves referencing and initializing the Windows App SDK Framework package at runtime. In addition, the Dynamic Dependencies API can be used to reference other framework packages outside of the Windows App SDK.

Use the Windows App SDK runtime

Packaged with external location and unpackaged apps must call the Bootstrapper API to use the Windows App SDK at run time. This is required before the app can use Windows App SDK features such as WinUI, App Lifecycle, MRT Core, and DWriteCore. A bootstrapper component enables packaged with external location and unpackaged apps to perform these important tasks:

- Find and load the Windows App SDK framework package to the app's package graph.
- Initialize the Dynamic Dependency Lifetime Manager (DDLM) for the Windows App SDK framework package. The purpose of the DDLM is to prevent servicing of the Windows App SDK framework package while it is in use by a packaged with external location or unpackaged app.

The simplest way to load the Windows App SDK runtime for packaged with external location and unpackaged apps is by setting the `<WindowsPackageType>None</WindowsPackageType>` property in your project file (.csproj or .vcxproj). You may also call the bootstrapper API directly in your app's startup code for more control over the initialization. For more details, see Use the Windows App SDK runtime for apps packaged with external location or unpackaged and Tutorial: Use the bootstrapper API in an app packaged with external location or unpackaged that uses the Windows App SDK.

Dynamic Dependencies support allows packaged with external location and unpackaged apps to keep their existing deployment mechanism, such as MSI or any installer, and be able to leverage the Windows App SDK in their application. Dynamic dependencies can be used by packaged, packaged with external location, and unpackaged apps; although it is primarily intended to be used by packaged with external location and unpackaged apps.

There is one DDLM for each version and architecture of the Windows App SDK framework package. This means on an `x64` computer, you may have both an `x86` and an `x64` version of the DDLM to support apps of both architectures.

Reference other framework packages using Dynamic Dependencies API

If you want to use features in other framework packages outside of the Windows App SDK (e.g., DirectX), packaged with external location and unpackaged apps can call the Dynamic Dependencies API. In addition to the bootstrapper component, the Windows App SDK also provides a broader set of C/C++ functions and WinRT classes that implement the *dynamic dependency API*. This API is designed to be used to reference any framework package dynamically at run time.

For more information, see Use MSIX framework packages dynamically from your desktop app and the Dynamic Dependencies sample

Deploy .winmd files to the target machine

Along with your app, we recommend that you go ahead and deploy Windows Metadata (`.winmd`) files. Metadata can be used by various APIs and behaviors at runtime, and its absence can limit or break functionality. For example, metadata can be used to marshal objects across apartments boundaries; and the need to marshal can be a function of machine performance. Since there's no deterministic way to know whether you need metadata, you should deploy `.winmd`s unless you're extremely concerned about size.

Use the Windows App SDK runtime for apps packaged with external location or unpackaged

Article • 04/19/2023

> **Note**
>
> If your app is installed by using MSIX technology, then see Windows App SDK deployment guide for framework-dependent packaged apps.

If your app isn't installed by using MSIX (that is, it's packaged with external location or unpackaged), then you must initialize the Windows App SDK for use before you can call Windows App SDK features such as WinUI 3, App Lifecycle, MRT Core, and DWriteCore. Your app must initialize the Windows App SDK runtime before using any other feature of the Windows App SDK.

- Beginning in Windows App SDK 1.0, that can be done automatically when your app starts via auto-initialization (set the project property `<WindowsPackageType>None</WindowsPackageType>`). For a demonstration, see Create your first WinUI 3 project.
- But if you have advanced needs (such as handling errors by showing your own custom UI or logging, or if you need to load a version of the Windows App SDK that's different from the version you built with), then continue reading this topic. In those scenarios, instead of auto-initialization, you can call the bootstrapper API explicitly.

Either of the two techniques above allows an app that doesn't use MSIX to take a dynamic dependency on the Windows App SDK at run time.

For background information about dynamic dependencies, see MSIX framework packages and dynamic dependencies.

Behind the scenes, and opting out of automatic module initialization

The code generated by the `WindowsPackageType` property mentioned above leverages module initializers to call the bootstrapper API. The bootstrapper does the heavy lifting to find the Windows App SDK and enable the current process to use it. The generated

code handles both initialization and shutdown. You can control initialization's behavior with the following project properties:

- `<WindowsAppSDKBootstrapAutoInitializeOptions_Default>true</WindowsAppSDKBootstrapAutoInitializeOptions_Default>`
  - Use default options.
- `<WindowsAppSDKBootstrapAutoInitializeOptions_None>true</WindowsAppSDKBootstrapAutoInitializeOptions_None>`
  - Use no options.
- `<WindowsAppSDKBootstrapAutoInitializeOptions_OnError_DebugBreak>true</WindowsAppSDKBootstrapAutoInitializeOptions_OnError_DebugBreak>`
  - Call DebugBreak() if an error occurs.
- `<WindowsAppSDKBootstrapAutoInitializeOptions_OnError_DebugBreak_IfDebuggerAttached>true</WindowsAppSDKBootstrapAutoInitializeOptions_OnError_DebugBreak_IfDebuggerAttached>`
  - Call DebugBreak() if an error occurs only if a debugger is attached to the process.
- `<WindowsAppSDKBootstrapAutoInitializeOptions_OnError_FailFast>true</WindowsAppSDKBootstrapAutoInitializeOptions_OnError_FailFast>`
  - Perform a fail-fast if an error occurs.
- `<WindowsAppSDKBootstrapAutoInitializeOptions_OnNoMatch_ShowUI>true</WindowsAppSDKBootstrapAutoInitializeOptions_OnNoMatch_ShowUI>`
  - Prompt the user to acquire the Windows App SDK runtime if a matching one cannot be found.
- `<WindowsAppSDKBootstrapAutoInitializeOptions_OnPackageIdentity_NoOp>true</WindowsAppSDKBootstrapAutoInitializeOptions_OnPackageIdentity_NoOp>`
  - Succceed if called in a process with package identity (otherwise it fails and an error is returned).

If you want your app to have explicit control, then you can directly call the boostrapper API early in your application's startup. In that case you don't need `WindowsPackageType` in your project file.

> **Note**
>
> In addition to the automatic initialization and the bootstrapper API, the Windows App SDK also provides an implementation of the *dynamic dependency API*. This API enables your unpackaged apps to take a dependency on *any* framework package (not just the Windows App SDK framework package), and it is used internally by the

bootstrapper API. For more information about the dynamic dependency API, see Use the dynamic dependency API to reference MSIX packages at run time.

Opting out of (or into) automatic module initialization

The project property `<WindowsAppSdkBootstrapInitialize>false</WindowsAppSdkBootstrapInitialize>` disables the automatic module initialization described above (the bootstrapper API isn't called). That allows your app to take responsibility and directly call the bootstrapper API.

As of version 1.2 of the Windows App SDK (from the stable channel), automatic module initialization applies only to projects that produce an executable (that is, the **OutputType** project property is set to *Exe* or *WinExe*). This is to prevent adding auto-initializers into class library DLLs and other non-executables by default. If you *do* need an auto-initializer in a non-executable (for example, a test DLL loaded by a host process executable that doesn't initialize the bootstrapper), then you can explicitly enable an auto-initializer in your project with `<WindowsAppSdkBootstrapInitialize>true</WindowsAppSdkBootstrapInitialize>`.

Using the bootstrapper API

> **Important**
>
> The **MddBootstrapInitialize2** function mentioned below is available starting in version 1.1.

The bootstrapper API consists of three C/C++ functions that are declared in the mddbootstrap.h header file in the Windows App SDK: **MddBootstrapInitialize**, **MddBootstrapInitialize2**, and **MddBootstrapShutdown**. Those functions are provided by the bootstrapper library in the Windows App SDK. That library is a small DLL that you must distribute with your app; it's not part of the framework package itself.

MddBootstrapInitialize2

This function initializes the calling process to use the version of the Windows App SDK framework package that best matches the criteria that you pass to the function parameters. Typically, that results in referencing the version of the framework package that matches the Windows App SDK NuGet package that's installed. If multiple packages meet the criteria, then the best candidate is selected. This function must be one of the

first calls in the app's startup to ensure the bootstrapper component can properly initialize the Windows App SDK and add the run-time reference to the framework package.

The bootstrapper API uses the Dynamic Dependencies API to add the Windows App SDK runtime's framework package to the current process's package graph and otherwise enable access to the package.

This function also initializes the Dynamic Dependency Lifetime Manager (DDLM). That component provides infrastructure to prevent the OS from servicing the Windows App SDK framework package while it's being used by an unpackaged app.

MddBootstrapShutdown

This function removes the changes to the current process that were made by a call to **MddBootstrapInitialize**. After this function is called, your app can no longer call Windows App SDK APIs, including the dynamic dependencies API.

This function also shuts down the Dynamic Dependency Lifetime Manager (DDLM) so that Windows can service the framework package as necessary.

.NET wrapper for the bootstrapper API

Although you can call the C/C++ bootstrapper API directly from .NET apps, that requires the use of platform invoke to call the functions. In Windows App SDK 1.0 and later releases, a .NET wrapper for the bootstrapper API is available in the `Microsoft.WindowsAppRuntime.Bootstrap.Net.dll` assembly. That assembly provides an easier and more natural API for .NET developers to access the bootstrapper's functionality. The **Bootstrap** class provides static **Initialize**, **TryInitialize**, and **Shutdown** functions that wrap calls to the **MddBootstrapInitialize** and **MddBootstrapShutdown** functions for most common scenarios. For an example that demonstrates how to use the .NET wrapper for the bootstrapper API, see the C# instructions in Tutorial: Use the bootstrapper API in an app packaged with external location or unpackaged that uses the Windows App SDK.

For more information about the .NET wrapper for the bootstrapper API, see these resources:

- Bootstrapper C# APIs.
- Section 6.1.4 of the dynamic dependencies specification.
- Bootstrap.cs: The open source implementation of the .NET wrapper for the bootstrapper API.

C++ wrapper for the bootstrapper API

A C++ wrapper for the bootstrapper API is available starting in Windows App SDK 1.1.

See Bootstrapper C++ API.

Declare OS compatibility in your application manifest

To declare operating system (OS) compatibility, and to avoid the Windows App SDK defaulting to Windows 8 behavior (and potential crashes), you can include a side-by-side application manifest with your packaged with external location or unpackaged app. See Application manifests (it's the file that declares things like DPI awareness, and is embedded into your app's `.exe` during build). This might be an issue if you're adding Windows App SDK support to an existing app, rather than creating a new one via a Visual Studio project template.

If you don't already have a side-by-side application manifest in your project, then add a new XML file to your project, and name it as recommended in Application manifests. Add to the file the **compatibility** element and the child elements shown in the following example. These values control the quirks level for the components running in your app's process.

Replace the **Id** attribute of the **maxversiontested** element with the version number of Windows that you're targeting (must be 10.0.17763.0 or a later release). Note that setting a higher value means that older versions of Windows won't run your app properly because every Windows release knows only of versions before it. So if you want your app to run on Windows 10, version 1809 (10.0; Build 17763), then you should either leave the 10.0.17763.0 value as is, or add multiple **maxversiontested** elements for the different values that your app supports.

XML

```xml
<?xml version="1.0" encoding="UTF-8"?>
<assembly xmlns="urn:schemas-microsoft-com:asm.v1" manifestVersion="1.0">
    <compatibility xmlns="urn:schemas-microsoft-com:compatibility.v1">
        <application>
            <!-- Windows 10, version 1809 (10.0; Build 17763) -->
            <maxversiontested Id="10.0.17763.0"/>
            <supportedOS Id="{8e0f7a12-bfb3-4fe8-b9a5-48fd50a15a9a}" />
        </application>
    </compatibility>
</assembly>
```

Tutorial: Use the bootstrapper API in an app packaged with external location or unpackaged that uses the Windows App SDK

Article • 03/17/2023

This article shows how to configure an app that's not installed by using MSIX (that is, it's packaged with external location or unpackaged) to use the bootstrapper API so that it explicitly loads the Windows App SDK runtime, and calls Windows App SDK APIs. Apps that are not installed via MSIX include apps packaged with external location, and unpackaged apps.

> **ⓘ Important**
>
> Beginning in the Windows App SDK 1.0, the default approach to loading the Windows App SDK from a packaged with external location or unpackaged app is to use *auto-initialization* via the `<WindowsPackageType>` project property (as well as making additional configuration changes). For the steps involved in auto-initialization in the context of WinUI 3 project, see Create your first WinUI 3 project. Or, if have an existing project that's not WinUI 3, then see Use the Windows App SDK in an existing project.
>
> If you have advanced needs (such as custom error handling, or to load a specific version of the Windows App SDK), then you can instead call the bootstrapper API explicitly. And that's the approach that this topic demonstrates. Also, for more info, see Use the Windows App SDK runtime for apps packaged with external location or unpackaged.

This topic demonstrates explicitly calling the bootstrapper API from a basic Console app project; but the steps apply to any unpackaged desktop app that uses the Windows App SDK.

Before completing this tutorial, we recommend that you review Runtime architecture to learn more about the *Framework* package dependency that your app takes when it uses the Windows App SDK, and the additional components required to work in a packaged with external location or unpackaged app.

Prerequisites

1. Install tools for the Windows App SDK.
2. Ensure that all dependencies for packaged with external location and unpackaged apps are installed (see Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged). An easy way to do that is to run the Windows App SDK runtime installer.

Instructions

You can follow this tutorial using a C# or a C++ project.

> **Note**
>
> The dynamic dependencies and bootstrapper APIs fail when called by an elevated process. As a result, Visual Studio shouldn't be launched elevated. See Dynamic Dependencies doesn't support elevation #567 for more details.

C#

Follow these instructions to configure a C# WinUI 3 project that's either packaged with external location, or unpackaged.

1. In Visual Studio, create a new C# **Console App** project. Name the project **DynamicDependenciesTest**. After you create the project, you should have a "Hello, World!" C# console app.

2. Next, configure your project.
   a. In **Solution Explorer**, right-click your project and choose **Edit Project File**.
   b. Replace the value of the **TargetFramework** element with a Target Framework Moniker. For example, use the following if your app targets Windows 10, version 2004.

   XML

   ```
   <TargetFramework>net8.0-windows10.0.19041.0</TargetFramework>
   ```

   a. Save and close the project file.

3. Change the platform for your solution to **x64**. The default value in a .NET project is **AnyCPU**, but WinUI 3 doesn't support that platform.

a. Select **Build** > **Configuration Manager**.
b. Select the drop-down under **Active solution platform** and click **New** to open the **New Solution Platform** dialog box.
c. In the drop-down under **Type or select the new platform**, select **x64**.
d. Click **OK** to close the **New Solution Platform** dialog box.
e. In **Configuration Manager**, click **Close**.

4. Install the Windows App SDK NuGet package in your project.
   a. In **Solution Explorer**, right-click the **Dependencies** node and choose **Manage Nuget Packages**.
   b. In the **NuGet Package Manager** window, select the **Browse** tab, and install the **Microsoft.WindowsAppSDK** package.

5. You're now ready to use the bootstrapper API (see Use the Windows App SDK runtime for apps packaged with external location or unpackaged) to dynamically take a dependency on the Windows App SDK framework package. This enables you to use the Windows App SDK APIs in your app.

   Open the **Program.cs** code file, and replace the default code with the following code to call the **Bootstrap.Initialize** method to initialize the bootstrapper. This code defines what version of the Windows App SDK the app is dependent upon when initializing the bootstrapper.

   > **ⓘ Important**
   >
   > You'll need to edit the code below to suit your specific configuration. See the descriptions of the parameters of the Bootstrap.Initialize method so that you can specify one of the versions of the Windows App SDK that you have installed.

   C#

```
using System;
using Microsoft.Windows.ApplicationModel.DynamicDependency;

namespace DynamicDependenciesTest
{
    class Program
    {
        static void Main(string[] args)
        {
            Bootstrap.Initialize(0x00010002);
            Console.WriteLine("Hello, World!");

            // Release the DDLM and clean up.
```

```
            Bootstrap.Shutdown();
        }
    }
}
```

At its root, the bootstrapper API is a native C/C++ API that enables you to use the Windows App SDK APIs in your app. But in a .NET app that uses the Windows App SDK 1.0 or later, you can use the .NET wrapper for the bootstrapper API. That wrapper provides an easier way of calling the bootstrapper API in a .NET app than calling the native C/C++ functions directly. The previous code example calls the static **Initialize** and **Shutdown** methods of the **Bootstrap** class in the .NET wrapper for the bootstrapper API.

6. To demonstrate that the Windows App SDK runtime components were loaded properly, add some code that uses the ResourceManager class in the Windows App SDK to load a string resource.

   a. Add a new **Resources File (.resw)** to your project (leave the default name).

   b. With the resources file open in the editor, create a new string resource with the following properties.

      - Name: **Message**
      - Value: **Hello, resources!**

   c. Save the resources file.

   d. Open the **Program.cs** code file, and replace the `Console.WriteLine("Hello, World!");` line with the following code.

```
C#

// Create a resource manager using the resource index generated
during build.
   var manager = new
Microsoft.Windows.ApplicationModel.Resources.ResourceManager("Dynam
icDependenciesTest.pri");

// Look up a string in the .resw file using its name.
Console.WriteLine(manager.MainResourceMap.GetValue("Resources/Messa
ge").ValueAsString);
```

   a. Click **Start Without Debugging** (or **Start Debugging**) to build and run your app. You should see the string `Hello, resources!` successfully displayed.

If your project is WPF

For a Windows Presentation Foundation (WPF) app, see Use the Windows App SDK in a WPF app.

Check for installed versions of the Windows App SDK runtime

Article • 08/19/2024

To check which versions of the Windows App SDK runtime are installed on your development computer, open a **PowerShell** window and run one of the following commands.

Powershell

```
# For 1.0 and 1.0 Preview releases and later
get-appxpackage *appruntime*
# For shorter output displaying only PackageFullName
(get-appxpackage micro*win*appruntime*).packagefullname

# For 1.0 Experimental
get-appxpackage *WindowsAppSDK*

# For version 0.8
get-appxpackage *reunion*
```

You should see output similar to the following, which will include the `x64`, `x86`, or `Arm64` versions of the Framework package, Dynamic Dependency Lifetime Manager (DDLM) package, Main package, and Singleton package, depending on your computer and Windows App SDK version.

Console

Remove outdated Windows App SDK runtime versions from your development computer

Article • 04/19/2023

As you install updated versions of the Windows App SDK runtime over time, you may want to remove outdated versions from your development computer. In general, you only need the Windows App SDK runtime and extension that you have chosen to reference and require in your application. Unless your application has specific reasons for earlier extensions or runtimes, you may safely remove older versions.

The Windows App SDK runtime includes the Framework, Main, Singleton, and Dynamic Dependency Lifetime Manager (DDLM) packages. All of these packages can be uninstalled by using **PowerShell** commands. The Main, Singleton, and DDLM packages can alternatively be uninstalled in **Settings**.

> **ⓘ Important**
>
> We recommend that you do not remove Windows App SDK runtime packages from end-user's machines after deployment. Doing so will break other applications that are taking a dependency on those packages.

Remove Windows App SDK runtime components using PowerShell

First, run the `get-appxpackage` command to list all versions of the Windows App SDK runtime packages that are installed on your computer (including the framework, main, singleton, and DDLM packages). The list includes details about each runtime package, including the **PackageFullName** value. For an example of the output of this command, see Check for installed versions of the Windows App SDK runtime.

Powershell

```
# For 1.0 and 1.0 Preview releases
get-appxpackage *appruntime*

# For 1.0 Experimental
get-appxpackage *WindowsAppSDK*
```

```
# For version 0.8
get-appxpackage *reunion*
```

Next, run the `remove-appxpackage` command to remove specific versions of the Windows App SDK runtime packages from your development computer. For each package, specify the **PackageFullName** value of the runtime packages you want to remove, as provided by the preceding step. The following example removes the framework, main, and DDLM package, respectively. Make sure you specify the correct **PackageFullName** values for the packages on your computer.

Powershell

```
remove-appxpackage -Package Microsoft.ProjectReunion.0.8-
preview_8000.144.525.0_x86__8wekyb3d8bbwe
remove-appxpackage -Package Microsoft.ProjectReunion.Main.0.8-
preview_8000.144.525.0_x64__8wekyb3d8bbwe
remove-appxpackage -Package Microsoft.ProjectReunion.DDLM.8000.144.525.0-x8-
p_8000.144.525.0_x86__8wekyb3d8bbwe
```

Remove main and DDLM packages in Settings

To remove the Main and Dynamic Dependency Lifetime Manager (DDLM) packages, you can alternatively use the **Apps & features** page in **Settings**.

> ⓘ **Note**
>
> The Windows App SDK framework package will not show up in **Apps & features**, and will need to be uninstalled using the **PowerShell** commands described earlier in this article.

On the **Apps & features** page, search for **reunion** to filter and show installed versions of Windows App SDK packages. Select any versions you want to remove from your computer and click **Uninstall**.

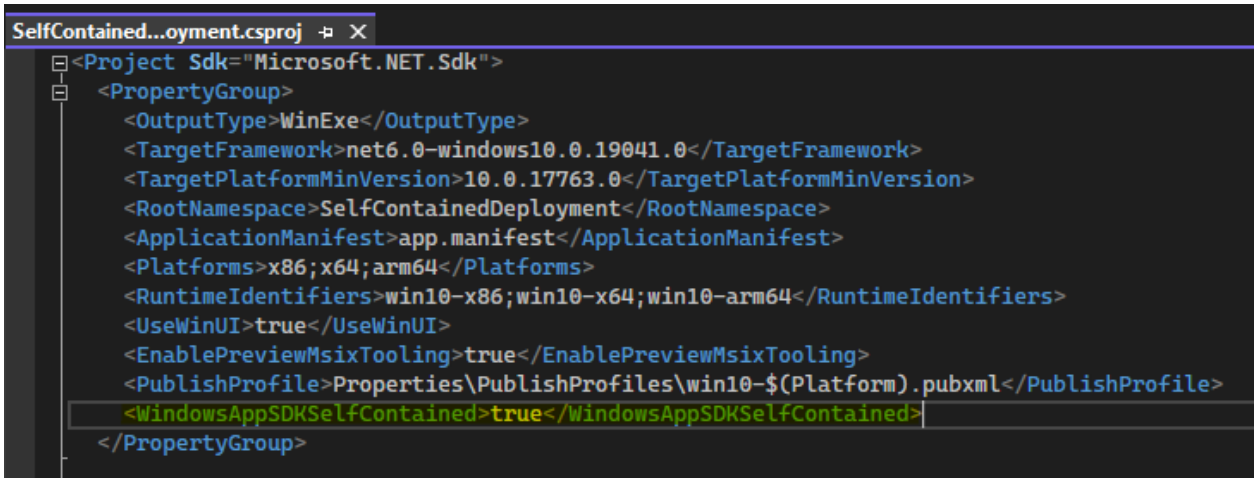
Windows App SDK deployment guide for self-contained apps

Article • 08/11/2023

A Windows App SDK project is framework-dependent by default. To switch to self-contained deployment, follow the steps below (the terms *framework-dependent* and *self-contained* are described in Windows App SDK deployment overview).

- In Visual Studio, right-click the app project node, and click **Edit Project File** to open the app project file for editing. For a C++ project, first click **Unload Project**.
- In the app project file, inside the main `PropertyGroup`, add `<WindowsAppSDKSelfContained>true</WindowsAppSDKSelfContained>` as shown in the screenshot below.



- For packaged projects, in the app project file, at the end of the file before the closing `</Project>`, add the `Target` shown below.

```
  <Target Name="_RemoveFrameworkReferences"
BeforeTargets="_ConvertItems;_CalculateInputsForGenerateCurrentProjectAppxMa
nifest">
    <ItemGroup>
      <FrameworkSdkReference Remove="@(FrameworkSdkReference)"
Condition="$([System.String]::Copy('%
(FrameworkSdkReference.SDKName)').StartsWith('Microsoft.WindowsAppRuntime.')
)" />
    </ItemGroup>
  </Target>
```

> **Note**

This is a workaround for a bug in Windows App SDK 1.1 and will not be necessary with Windows App SDK 1.2. It is only required for packaged projects.

- Save and close the project file.
- Click **Reload Project**.
- If you're using a **Windows Application Packaging Project** (rather than the single-project MSIX that you get with **Blank App, Packaged (WinUI 3 in Desktop)**), then make all of the above changes in the project file for the packaging project as well.

> **Note**
>
> Library projects should not be changed. Self-contained deployment should only be configured in app projects (and, where applicable, in a **Windows Application Packaging Project**).

For sample apps, see Windows App SDK self-contained deployment samples.

Having set the `WindowsAppSDKSelfContained` property to `true` in your project file, the contents of the Windows App SDK Framework package will be extracted to your build output, and deployed as part of your application.

> **Note**
>
> .NET apps need to be **published as self-contained** as well to be fully self-contained. See **this sample** for how to configure .NET self-contained with publish profiles. `dotnet publish` is not yet supported with Windows App SDK 1.1.

> **Note**
>
> C++ apps need to use the **hybrid CRT** as well to be fully self-contained. Importing **HybridCRT.props** from **Directory.Build.props** is the recommended way to configure it for all projects in a solution (see an example in **Directory.Build.props**). A packaged app must also set `<UseCrtSDKReferenceStaticWarning>false</UseCrtSDKReferenceStaticWarning>` in their project file. See the **Self-contained deployment** sample app for how to use the hybrid CRT.

If your app is packaged (for more info, see Deployment overview), then the Windows App SDK dependencies will be included as content inside the MSIX package. Deploying

the app still requires registering the MSIX package like any other packaged app.

If your app is packaged with external location or unpackaged, then the Windows App SDK dependencies are copied next to the `.exe` in your build output. You can xcopy-deploy the resulting files, or include them in a custom installer.

Dependencies on additional MSIX packages

A small number of APIs in the Windows App SDK rely on additional MSIX packages that represent critical operating system (OS) functionality.

- For example (as of the Windows App SDK 1.1), push notifications APIs (PushNotificationManager) and app notifications APIs (AppNotificationManager) have a dependency on the *Singleton* package (see Deployment architecture for the Windows App SDK).

That means that if you want to use those APIs in a self-contained app, then you have the following options:

1. You could make your functionality optional, and light it up *only if and when possible*. Calling the APIs' **IsSupported** method (PushNotificationManager.IsSupported and AppNotificationManager.IsSupported) will let you check dynamically at runtime whether or not the APIs are available to the calling app on the system it's running on.

    - This enables safe, conditional, optional use of the APIs without compromising the simplicity of your self-contained deployment.
    - Only if the OS services are installed outside of your app deployment will your app light up the appropriate functionality. But in fact there are *some* cases where the APIs will work even without the Singleton package being present; so calling **IsSupported** to check is often a good idea.

2. Deploy the required MSIX packages as part of your app installation.

    - This allows you to depend on the API in all scenarios. But requiring MSIX package deployment of dependencies as part of your app deployment can compromise the simplicity of self-contained deployment.

3. Don't use the API.

    - Consider alternative APIs that provide similar functionality without additional deployment requirements.

Opting out of (or into) automatic UndockedRegFreeWinRT support

The project property **WindowsAppSdkUndockedRegFreeWinRTInitialize** was introduced in version 1.2 of the Windows App SDK (from the stable channel). If that property is set to *true* then it ensures that the Windows App SDK's implementation of undocked registration-free Windows Runtime (*UndockedRegFreeWinRT*) is enabled automatically at app startup. That support is needed by unpackaged self-contained apps.

WindowsAppSdkUndockedRegFreeWinRTInitialize defaults to *true* if **WindowsAppSDKSelfContained** is *true* and **WindowsPackageType** is *None* and (as of version 1.2 of the Windows App SDK) **OutputType** project property is set to *Exe* or *WinExe* (that is, the project produces an executable). That last condition is to prevent adding automatic UndockedRegFreeWinRT support into class library DLLs and other non-executables by default. If you *do* need automatic UndockedRegFreeWinRT support in a non-executable (for example, a test DLL loaded by a host process executable that doesn't initialize UndockedRegFreeWinRT), then you can explicitly enable it in your project with `<WindowsAppSdkUndockedRegFreeWinRTInitialize>true</WindowsAppSdkUndockedRegFreeWinRTInitialize>`.

Set up continuous integration for your WinUI 3 app

Article • 03/20/2023

You can use GitHub Actions to set up continuous integration builds for WinUI 3 projects. In this article, we'll look at different ways to do this. We'll also show you how to perform these tasks by using the command line so that you can integrate with any other build system.

Prerequisites

- Start with a single-project MSIX WinUI 3 app or migrate your project to use single-project MSIX.
- Sign up for GitHub and create a repository if you haven't done so already.

Step 1: Set up your certificate

MSIX apps must be signed in order to be installed. If you already have a certificate, you can skip this step. You can easily create a test certificate by opening your app in Visual Studio, right clicking your WinUI 3 project, and selecting **Package and Publish** -> **Create App Packages**.

Then select **Next** to move to the **Select signing method** page, and click the **Create...** button to create a new certificate. Choose the publisher name and **leave the password field blank**, and create the certificate.

Then, close/cancel out of the dialogs and notice that a new **.pfx** file has been created in your project. This is the certificate you can sign your MSIX with!

Step 2: Add your certificate to the Actions secrets

You should avoid submitting certificates to your repo if at all possible, and git ignores them by default. To manage the safe handling of sensitive files like certificates, GitHub supports secrets.

To upload a certificate for your automated build:

1. **Encode your certificate as a Base 64 string**: Open PowerShell to the directory that contains your certificate, and execute the following command, replacing the pfx file name with your certificate's file name.

PowerShell

```
$pfx_cert = Get-Content 'App1_TemporaryKey.pfx' -AsByteStream

[System.Convert]::ToBase64String($pfx_cert) | Out-File
'App1_TemporaryKey_Base64.txt'
```

2. In your GitHub repository, go to the **Settings** page and click **Secrets** on the left.
3. Click **New repository secret**, name it `BASE64_ENCODED_PFX`, and copy/paste the text from the text file in the PowerShell output into the secret value.

Step 3: Set up your workflow

Next, in your repository, go to the Actions tab and create a new workflow. Chose the **set up a workflow yourself** option instead of one of the workflow templates.

Copy/paste the following into your workflow file, and then update...

1. **Solution_Name** to the name of your solution
2. **dotnet-version** to either 5.0 or 6.0 depending on your project

> ⓘ Note
>
> For the step uploading the artifact (the last step below), if the build output doesn't land in a folder that contains your solution, then replace `env.Solution_Name` with `github.workspace` (the GitHub actions Workspace folder).

yml

```
# This workflow will build, sign, and package a WinUI 3 MSIX desktop
application
# built on .NET.

name: WinUI 3 MSIX app

  push:
    branches: [ main ]
  pull_request:
    branches: [ main ]
```

```yaml
jobs:

  build:

    strategy:
      matrix:
        configuration: [Release]
        platform: [x64, x86]

    runs-on: windows-latest  # For a list of available runner types, refer
to
                             #
https://help.github.com/en/actions/reference/workflow-syntax-for-github-
actions#jobsjob_idruns-on

    env:
      Solution_Name: your-solution-name                         # Replace
with your solution name, i.e. App1.sln.

    steps:
    - name: Checkout
      uses: actions/checkout@v2
      with:
        fetch-depth: 0

    # Install the .NET Core workload
    - name: Install .NET Core
      uses: actions/setup-dotnet@v1
      with:
        dotnet-version: 6.0.x

    # Add  MSBuild to the PATH: https://github.com/microsoft/setup-msbuild
    - name: Setup MSBuild.exe
      uses: microsoft/setup-msbuild@v1.0.2

    # Restore the application to populate the obj folder with
RuntimeIdentifiers
    - name: Restore the application
      run: msbuild $env:Solution_Name /t:Restore
/p:Configuration=$env:Configuration
      env:
        Configuration: ${{ matrix.configuration }}

    # Decode the base 64 encoded pfx and save the Signing_Certificate
    - name: Decode the pfx
      run: |
        $pfx_cert_byte = [System.Convert]::FromBase64String("${{
secrets.BASE64_ENCODED_PFX }}")
        $certificatePath = "GitHubActionsWorkflow.pfx"
        [IO.File]::WriteAllBytes("$certificatePath", $pfx_cert_byte)

    # Create the app package by building and packaging the project
    - name: Create the app package
      run: msbuild $env:Solution_Name /p:Configuration=$env:Configuration
/p:Platform=$env:Platform
```

```
/p:UapAppxPackageBuildMode=$env:Appx_Package_Build_Mode
/p:AppxBundle=$env:Appx_Bundle
/p:PackageCertificateKeyFile=GitHubActionsWorkflow.pfx
/p:AppxPackageDir="$env:Appx_Package_Dir" /p:GenerateAppxPackageOnBuild=true
      env:
        Appx_Bundle: Never
        Appx_Package_Build_Mode: SideloadOnly
        Appx_Package_Dir: Packages\
        Configuration: ${{ matrix.configuration }}
        Platform: ${{ matrix.platform }}

    # Remove the pfx
    - name: Remove the pfx
      run: Remove-Item -path GitHubActionsWorkflow.pfx

    # Upload the MSIX package:
https://github.com/marketplace/actions/upload-a-build-artifact
    - name: Upload MSIX package
      uses: actions/upload-artifact@v2
      with:
        name: MSIX Package
        path: ${{ env.Solution_Name }}\\Packages
```

Step 4: Commit the workflow and watch it run!

Commit the workflow file to your main branch, and then go to the Actions tab on your GitHub repository and watch your workflow run! It should successfully run and produce artifacts that contain your built MSIX app.

Building from command line

If you want to build your solution by using the command line, or by using any other CI system, run MSBuild with these arguments. The `GenerateAppxPackageOnBuild` property causes the MSIX package to be generated.

PowerShell

```
/p:AppxPackageDir="Packages"
/p:UapAppxPackageBuildMode=SideloadOnly
/p:AppxBundle=Never
/p:GenerateAppxPackageOnBuild=true
```

Windows app restore: maximize the value of your app

Article • 09/29/2023

To maximize retention of your users as they move to a new device, your app (in conjunction with Windows app restore) should offer the best possible restore experience. This topic defines the tenets of Windows app restore that will enable your app to deliver that experience and keep as many of your customers engaged as possible.

Why app restore is critical

When the users of your app move to their next Windows PC, they need the peace of mind that their apps will transfer over to their new device.

Windows will back up the user's app list to the cloud; during restore, it will create pinned app placeholders on the new Windows PC so that users find their apps right where they expect them to be. This makes installation of the app very straightforward. However, in addition to the application install, users also want the rest of their app configuration and settings to transfer over to their new device.

If you ensure that your apps are following best practices to maximize the effectiveness of Windows app restore capabilities, then your users will be able to get back to productivity as quickly as possible on their new PC. This will, in turn, allow your app to retain your users on their new PC. The rest of this topic discusses those best practices.

App restore tenets

These tenets are guidelines and best practices for you to enable an optimal backup and restore experience for the users of your apps. These are a collection of existing best practices that we've gathered.

- **Publish your app to the Microsoft Store**. Your app should enable trusted distribution through the Microsoft Store (see Publish Windows apps and games). This is the easiest way for you to provide a trusted and seamless (think fewer clicks) experience for your users.
- **Package your app**. Your app should be *packaged* (for definitions, see Deployment overview). A packaged app enables the system to better understand the files, data,

and settings that matter to an app; and enables the system to more easily restore apps on demand.

- **Store critical app state in the cloud**. Your app should store its critical app state in the cloud. Having an app installed on a new device is only the first step. Getting users seamless back to their prior app state—their recents, their favorites, their preferences—is the goal; and the best way to do this is to store that critical user state information in the cloud. Local state should be thought of as only a temporary optimization.
- **Write user-generated content to Known Folders**. Your app should write user-generated content to the Windows known folders (see the **KnownFolders** class). Keep it separate from app state—if your app produces user-generated content (files, sound clips, videos, etc.), then you should write that content to the Windows Known Folders (Documents, Pictures, Music, Videos, etc.). This enables Windows, via OneDrive, to back up those files to the cloud and fluidly keep in sync across devices using its files-on-demand technology.

Publish your app to the Microsoft Store

The Microsoft Store is the most reliable distribution cloud for your Windows apps (see Publish Windows apps and games). Users can easily search for and find your app for installation.

When a user installs a new operating system (OS), and chooses to restore from their previous PC, those apps that are in the Microsoft Store will automatically be listed in the **All Apps** list, and have pins available in the same locations on the **Start** menu and taskbar as before. Those shortcuts allow the user to immediately access the app and install it.

Package your app

Another key to creating a great experience for your users is ensuring that the app gets installed, and behaves correctly. The best way to do that is with a *packaged* app (see Deployment overview).

A packaged app (either a packaged desktop app or a Universal Windows Platform app) is packaged using MSIX, and it's run inside of a lightweight app container. The packaged app process and its child processes run inside the container; and they're isolated using file system and registry virtualization. It's these aspects of packaging that make installation extremely reliable, and ensure that the app doesn't misbehave or leave registry configuration or app files on the PC when the user uninstalls.

For more info about the benefits of using MSIX for packaging, see What is MSIX?.

The benefits of the MSIX format, and packaged apps, don't end with app reliability. Packaging your app also means that it will be able to be quickly installed when users migrate to a new PC. Following an install, Windows will begin rehydrating the packaged apps that it restored. Since rehydrating takes time, if the user clicks the link before the app is rehydrated, then Windows will immediately download and install the app, allowing the user to run it as early as possible.

Store critical app state in the cloud

As you can see, Windows does a great job in helping your customers find and install your app on their new PC. But what about app data, such as app settings? To deliver the best user experience, we recommend that you use the cloud to store your app's state. By storing app data in the cloud, your users can have a consistent experience across devices. And when users don't need to reconfigure their app settings, your user satisfaction rises dramatically.

Storing app settings to the cloud requires a service. To provide as rich an experience as possible, Microsoft provides a variety of services that eliminate the need to spin up servers, or pick your database, or worry about scale or security. Those services provide a great developer experience that lets you store application data in the cloud by using SQL or NoSQL APIs. To help build scalable and robust applications, you can also sync data on all devices, and enable the application to work with or without a network connection. For more info about Microsoft services, see Store, sync, and query mobile application data from the cloud.

For more info about the best practices of storing app data, see Store and retrieve settings and other app data.

Write user-generated content to Known Folders

Windows introduced known folders with Windows Vista. Since that time, users have come to expect that they can find the content they create with their apps in those locations. Writing user-generated content to those locations has the added benefit that OneDrive will back up those folders, if enabled, to ensure they're available to the user on their new PC (see Back up your folders with OneDrive). By using standard Windows APIs to write your user-generated content to the known folders, you're improving the user experience, and decreasing friction in adopting your app.

User-visible files

You should store files that you wish a user to see and to interact with in the appropriate folder in the user's profile. You should store general files in the `FOLDERID_Documents` location; typically in a sub-folder. And you should store pictures, music, and video in their appropriate `FOLDERID_Pictures`, `FOLDERID_Music`, and `FOLDERID_Videos` locations.

Machine-specific app data

You should store data that's specific to the machine on which the app is currently running in the `FOLDERID_LocalAppData` folder; normally in a sub-folder. That includes data such as:

- System performance metrics. Information gathered and persisted about the current machine, and used to optimize the behavior of the app on that specific machine. For example, if you've gathered info about the machine's graphics capabilities and performance (in order to determine the optimal rendering quality), then you shouldn't roam that data.
- User customizations connected with machine-specific capabilities. An app that optimizes its rendering performance based on the machine's graphics capabilities and performance should also store any changes that it allows the user to make to those preferences as machine-specific data. That ensures that the user enjoys what they determine to be the best experience for the machine they happen to be running on the app on.

> **Tip**
>
> The reason we advise not to store machine-specific data in known folders is that those user-specific folders travel with the user between machines (they *roam*). So storing machine-specific data can result in conflicts and problems when users use your app on multiple machines, or after an upgrade.

App data that's not machine-specific

You should store data that's not machine-specific in the `FOLDERID_Documents` location; typically in a sub-folder. Those files often contain user-provided app customization such as: default action to perform on launch; custom backgrounds; or other data that shouldn't change from one machine to another.

Best practices for unpackaged apps

If you can't package your app, then be sure that your installer implements the recommendations below. That will ensure that it's possible to backup and restore the **Start** menu shortcuts that enable installing on a new machine that's restored from backup.

- Make sure that your installer specifies an `InstallLocation` value in its uninstall registry key. When using Windows Installer specify this using ARPINSTALLLOCATION. That's needed in order to enable the mapping of the **Start** menu shortcuts to the product.
- Make sure that that location is specific to the product; usually the sub-directory under `C:\Program Files\<Publisher>\<Application>`.
- Make sure that your **Start** menu shortcuts have machine-independent `System.AppUserModel.ID` (AMUID) values. That's best done by specifying them explicitly in the shortcut metadata. For more info, see Where to Assign an AppUserModelID.

Get started: Publish your first app in the Microsoft Store

Article • 12/04/2024

Introduction

Distributing apps via Microsoft Store is a good choice for developers of any app type and size. The Microsoft Store is a centralized hub for Windows users to discover and install a wide range of apps, providing developers access to a vast audience of over a billion users across Windows 10 and Windows 11. Microsoft Store also offers you various ways to make money from your apps, and lets you choose your own commerce platform and revenue sharing model. Microsoft Store also supports a wide range of app types and technologies, and allows you to bring your traditional desktop apps to the Store without changing your code or installer.

For the full benefits of publishing your app into the Microsoft Store, please visit benefits of distributing your apps via Microsoft Store.

Prerequisite

A Windows app developer account in Partner Center is needed before you start the app submission process. There are 2 types of developer accounts available in Partner Center: **Individual and Company**.

To understand how to open developer account, you can watch the following video:

Open individual developer account

Who should select an individual account:

- **Independent developers** whose distribution of apps through the Store is **not in relation to their business, trade, or profession**
- **Small scale creators** producing content for non-commercial purposes
- Individuals creating digital content as a **hobbyist, amateur, school, or personal project**

The individual account costs approximately **$19 USD**. It is a one-time registration fee. (The fees varies depending on your country or region)

https://learn-video.azurefd.net/vod/player?id=663fa063-4205-4b88-a473-4a2782d49197&locale=en-us&embedUrl=%2Fwindows%2Fapps%2Fpublish%2F

For more details, refer steps to create individual developer account.

Get started with app submission

MSIX or PWA

We recommend packaging your app (which is built with any app framework - UWP, Win32, PWA, WinApp SDK etc.), as MSIX. By packaging your app as MSIX, you can take advantages of many features like a complimentary binary hosting (provided by Microsoft), complementary code signing (provided by Microsoft), Microsoft Store commerce platform, package flighting, advanced integration with Windows (to use features like share dialog, launch from Store etc), Windows 11 backup and restore etc.

For packaging your Win32 app as MSIX, follow these steps.

Note: If you distribute your application as a web download (EXE /MSI) and you are planning to distribute it as a packaged application (MSIX) in the Store, you might want to prevent users from installing both versions or migrate users from the unpackaged web version to the Store version. Learn more about transitioning users from web unpackaged to Store packaged app.

Choice of commerce platform

Microsoft Store offers developers a flexible and transparent revenue sharing model (including in-app purchases, subscriptions, ads, and tips) that lets you choose your own commerce platform and keep 100% of the revenue for non-gaming apps, or use Microsoft's commerce platform and pay a competitive fee of 12% for games and 15% for apps. This means that you can maximize your profit and control your business model, while benefiting from the convenience and security of Microsoft's commerce platform.

App submission [MSIX/PWA]

To understand the submission process of MSIX apps, you can watch the following video.

https://learn-video.azurefd.net/vod/player?id=4f68f734-a116-4cae-a0a3-89a415087e61&locale=en-us&embedUrl=%2Fwindows%2Fapps%2Fpublish%2F

For more details, refer to the steps below.

Reserve your app's name [MSIX/PWA]

All apps on the Microsoft Store must have a unique name. To secure a name for your app, the first step is to reserve it, which you can do up to three months before publishing, even if development has not started.

Steps to Reserve Your App's Name:

1. Navigate to the Partner Center apps and games page.
2. Click **New product**.
3. Click on **MSIX** or **PWA** app. If you want to submit an MSIX or PWA game, click on **Game**.
4. Enter the name you would like to use and click **Check availability**. If the name is available, you will see a green check mark. If the name is already in use, you will see a message indicating so.
5. Once you have selected an available name that you would like to reserve, click **Reserve product name.**

For more information, please visit Reserve your app's name - Windows apps | Microsoft Learn.

Create your app submission [MSIX/PWA]

1. After reserving an app name, you will be redirected to Application overview page. Click on **Start Submission**. A product submission in draft status will appear. This draft includes all the submission steps that need to be completed.
2. For submitting a PWA, learn how to convert your website into a PWA.
3. Complete each tab of the submission draft:
    - **Pricing and Availability**: Provide the price of your app, where it will be available to customers and decide whether you'll offer a free trial by setting pricing and availability for your app. Set app pricing and availability - Windows apps | Microsoft Learn

- **Properties**: Define your app's category, secondary category, sub-category and provide system requirements for your app, by entering your app properties. Enter app properties - Windows apps | Microsoft Learn
- **Age Ratings**: For your app to receive the appropriate age and content ratings administered by the IARC rating system, answer age rating questionnaire and generate the age rating. Age ratings for MSIX apps - Windows apps | Microsoft Learn
- **Packages**: Upload the app packages for your app which will be downloaded by the Store user. Upload app packages - Windows apps | Microsoft Learn
- **Store Listings**: Enter the app description, screenshots, and logos that will be displayed on your app's Product Details Page (PDP) in the Store, by creating a Store listing. Create app store listings - Windows apps | Microsoft Learn
- **Submission options (optional)**: Enter notes for certification or decide when your app should publish to the Store using submission options. Manage submission options - Windows apps | Microsoft Learn

4. After you complete a section, click on **Save**. Once all sections are complete and you are ready to submit, click on **Submit for certification**.

If your draft is missing any necessary information, it will be marked as **Incomplete.**

For more information, please visit Create an app submission - Windows apps | Microsoft Learn.

App certification process [MSIX/PWA]

When you finish creating your app's submission and click Submit to the Store, the submission enters the certification step. This process can take up to three business days. During certification, we will perform security tests, technical compliance tests and also a content compliance check on you app submission. You will be notified if your submission fails any of these tests.

After your submission passes certification, on an average, customers will be able to see the app's listing within 15 minutes depending on their location. You will be notified when your submission is published to the Store, and the app's status in the dashboard change to 'In Microsoft Store'.

To understand the certification process of MSIX apps, you can watch the following video.

https://learn-video.azurefd.net/vod/player?id=4f55d620-642f-4653-8fb4-1d2e49e3dff4&locale=en-us&embedUrl=%2Fwindows%2Fapps%2Fpublish%2F

For more information, please visit The app certification process - Windows apps | Microsoft Learn.

Post-certification [MSIX/PWA]

Analyze performance for MSIX apps and games

View detailed analytics for your apps and games in Partner Center. Statistics and charts let you know how your apps are performing in the Store; from how many customers you have reached to how they are using your app and what they have to say about it. You can also find metrics on app install, app health, app usage, and more. You can view analytic reports right in Partner Center or download the reports you need to analyze your data offline. We also provide several ways for you to access your analytics data outside of Partner Center.

To understand how to analyze your MSIX app's performance, you can watch the following video.

https://learn-video.azurefd.net/vod/player?id=fa8f1e24-e923-4ec1-b4b4-83956ef3ed51&locale=en-us&embedUrl=%2Fwindows%2Fapps%2Fpublish%2F

For more details, you can refer to the following reports.

Reports available for your apps

There are different reports available for your apps, check the descriptions to find the metrics you are looking for.

Expand table

Report	Description
Acquisitions report	See how many people have seen and installed your app in Store. You can also review data for different acquisition channels, markets, and platform details in this report.

Report	Description
Add-on acquisition report	See how many add-ons you have sold, along with demographic and platform details.
Usage report	See how customers on Windows 10 or Windows 11 (including Xbox) are using your app, including data about custom events that you have defined.
Health report	Get data related to the performance and quality of your app, including crashes and unresponsive events.
Reviews report	See the rating and reviews your customers have left for your app and provide responses to let customers know you are listening to their feedback.
Insights report	See meaningful insights about your app like significant (changes increases or decreases that we detected over the last 30 days in your acquisitions and health data).

Appendix [MSIX/PWA]

Windows App SDK

Article • 07/15/2024

The Windows App SDK is a set of new developer components and tools that represent the next evolution in the Windows app development platform. The Windows App SDK provides a unified set of APIs and tools that can be used in a consistent way by any desktop app on Windows 11 and downlevel to Windows 10, version 1809.

The Windows App SDK doesn't replace the Windows SDK or existing desktop Windows app types such as .NET (including Windows Forms and WPF) and desktop Win32 with C++. Instead, the Windows App SDK complements those existing tools and app types with a common set of APIs that developers can rely on across these platforms. For more details, see Benefits of the Windows App SDK.

> **Important**
>
> If you're working on a UWP app, then refer to **Migrate from UWP to the Windows App SDK**.

Get started with the Windows App SDK

The Windows App SDK provides extensions for Visual Studio 2022 and Visual Studio 2019. Those extensions include project templates configured to use the Windows App SDK components in new projects. The Windows App SDK libraries are also available via a NuGet package that you can install in existing projects.

To learn about configuring Visual Studio for creating new Windows App SDK projects, including the required workloads and components, see Getting Started with WinUI.

If you've already installed the required developer tools, then you're ready to Create your first WinUI 3 project. You can also use the Windows App SDK in an existing project.

For guidance on specific Windows App SDK versions, see Release channels and Downloads.

Windows App SDK features

The following table highlights the development features that are provided by the current releases of the Windows App SDK. For more details about the release channels

of the Windows App SDK that include each of these features, see Features available by release channel.

Expand table

Feature	Description
WinUI 3	The premiere native user interface (UI) framework for Windows desktop apps, including managed apps that use C# and .NET and native apps that use C++ with the Win32 API. WinUI 3 provides consistent, intuitive, and accessible experiences using the latest user interface (UI) patterns.
Render text with DWriteCore	Render text using a device-independent text layout system, high quality sub-pixel Microsoft ClearType text rendering, hardware-accelerated text, multi-format text, wide language support, and much more.
Manage resources with MRT Core	Manage app resources such as strings and images in multiple languages, scales, and contrast variants independently of your app's logic.
App lifecycle: App instancing	Control whether multiple instances of your app's process can run at the same time.
App lifecycle: Rich activation	Process information about different kinds activations for your app.
App lifecycle: Power management	Gain visibility into how your app affects the device's power state, and enable the app to make intelligent decisions about resource usage.
Manage app windows	Create and manage the windows associated with your app.
Push notifications	Send raw notifications and app notifications to your app from the cloud using Azure App Registration identities.
App notifications	Send app notifications to your app locally.
Deployment	Deploy Windows App SDK runtime with your unpackaged and packaged app

Windows App SDK release channels

The following table provides an overview of the different release channels.

Expand table

Release channel	Description
Stable	This channel is supported for use by apps in production environments. It only includes stable APIs. By default, the Windows App SDK docs focus on the Stable channel.
Preview	This channel provides a preview of the next stable release. There may be breaking API changes between a given preview channel release and the next stable release. For documentation on using the Preview release, see Install tools for preview and experimental channels of the Windows App SDK.
Experimental	This channel includes experimental features that are in early stages of development. Experimental features may be removed from the next release, or may never be released. For documentation on using the Experimental release, see Install tools for preview and experimental channels of the Windows App SDK.

For more details about the release channels of the Windows App SDK, see Windows App SDK release channels.

Benefits of the Windows App SDK for Windows developers

The Windows App SDK provides a broad set of Windows APIs with implementations that are decoupled from the OS and released to developers via NuGet packages. The Windows App SDK is not meant to replace the Windows SDK. The Windows SDK will continue to work as is, and there are many core components of Windows that will continue to evolve via APIs that are delivered via OS and Windows SDK releases. Developers are encouraged to adopt the Windows App SDK at their own pace.

Unified API surface across desktop app platforms

Developers who want to create desktop Windows apps must choose between several app platforms and frameworks. Although each platform provides many features and APIs that can be used by apps that are built using other platforms, some features and APIs can only be used by specific platforms. The Windows App SDK unifies access to Windows APIs for desktop Windows 11 and Windows 10 apps. No matter which app model you choose, you will have access to the same set of Windows APIs that are available in the Windows App SDK.

Over time, we plan to make further investments in the Windows App SDK that remove more distinctions between the different app models. For example, your app might use the WinUI Desktop model, it might use the XAML Islands model, it might use WPF, or it

could be a non-XAML app that uses Composition Islands or other aspects of the Windows App SDK. In any of these cases, we aim to make access to the Windows APIs in the Windows App SDK the same easy experience. The Windows App SDK will include both WinRT APIs and native C APIs.

Consistent experience across Windows versions

As the Windows APIs continue to evolve with new OS versions, developers must use techniques such as version adaptive code to account for all the differences in versions to reach their application audience. This can add complexity to the code and the development experience.

Windows App SDK APIs will work on Windows 11 and downlevel to Windows 10, version 1809. This means that as long as your customers are on Windows 10, version 1809, or any later version of Windows, you can use new Windows App SDK APIs and features as soon as they are released, and without having to write version adaptive code.

Faster release cadence

New Windows APIs and features are usually shipped within major Windows OS updates that release about once a year (often less frequently). Windows App SDK ships new releases about once every six months. This release cadence ensures that you continuously have access to the latest innovations in the Windows development platform.

Give feedback and contribute

We are building the Windows App SDK as an open source project. We have a lot more information on our Github page about how we're building the Windows App SDK, and how you can be a part of the development process. Check out our contributor guide to ask questions, start discussions, or make feature proposals. We want to make sure that the Windows App SDK brings the biggest benefits to developers like you.

Windows App SDK and supported Windows releases

Article • 10/23/2024

This topic identifies the versions of the Windows client and Windows Server operating systems (OS) supported by the Windows App SDK, along with the various servicing categories, channels, and SKUs for each OS.

This table summarizes the Windows client and server releases supported by the Windows App SDK (the following sections provide details on the various servicing categories, channels, and SKUs for each OS).

Expand table

Windows App SDK	Release date	Windows client	Windows Server
1.5	2024-02-29	Win10 1809 Win10 21H2 Win10 22H2 Win10 23H2 Win11 21H2 Win11 22H2 Win11 23H2 Win11 24H2	Server 2019 Server 2022
1.6	2024-09-04	Win10 1809 Win10 21H2 Win10 22H2 Win10 23H2 Win11 21H2 Win11 22H2 Win11 23H2 Win11 24H2	Server 2019 Server 2022

Windows client SKUs and channels

The Windows client OS runs on personal devices such as workstations, desktop PCs, laptops, and tablets.

There are four servicing categories that apply to various combinations of Windows client SKUs and servicing channels.

Expand table

Servicing channel		SKU	SKU
		Home, Pro	Enterprise
GA*		Shortest servicing	Short servicing
LTSC**	Mainstream	N/A	Long servicing
	Extended	N/A	Longest servicing

* The General Availability (GA) servicing channel includes the majority of Windows devices.

** The Long Term Servicing Channel (LTSC) includes devices that need to continue running older versions of Windows.

Five older versions of Windows client are still in service for at least one servicing category. Each version will continue to be supported by the Windows App SDK until the latest applicable Windows servicing end-date for that version. The following table shows the end-date for each servicing category.

Expand table

Version	Build	Servicing end-dates				Max end-dates
		GA Home, Pro	GA Enterprise	LTSC Mainstream	LTSC Extended	
Win10 1809	17763	Past	Past	Past	2029-01-09	2029-01-09
Win10 21H2	19044	Past	2024-06-11	2027-01-12	2032-01-13	2032-01-13
Win10 22H2	19045	2025-10-14	2025-10-14	N/A	N/A	2025-10-14
Win11 21H2	22000	Past	2024-10-08	N/A	N/A	2024-10-08
Win11 22H2	22621	2024-10-08	2025-10-14	N/A	N/A	2025-10-14
Win11 23H2	22631	2025-11-11	2026-11-10	N/A	N/A	2026-11-10
Win11	26100	2026-10-13	2027-10-12	2029-10-09	2034-10-10	2034-10-10

24H2

Windows Server SKUs and channels

Windows Server is the platform for building an infrastructure of connected applications, networks, and web services, from the workgroup to the data center. Windows Server offers services to other devices, has more features and capacities than a client OS, and can support more network connections.

The following table shows the end-date for each servicing category.

Expand table

Version	Build	Servicing end-dates		Max end-dates
		LTSC Mainstream	LTSC Extended	
Server 2019	17763	Past	2029-01-09	2029-01-09
Server 2022	20348	2026-10-13	2031-10-14	2032-01-13

Windows App SDK release channels

Article • 01/15/2025

The latest version of the Windows App SDK ships via three release channels: Experimental, Preview, and Stable. The following table provides an overview of these release channels.

> **Note**
>
> When you Install tools for the Windows App SDK, install the release channel that best serves your development scenario.

Expand table

	Channel	Description	Release cadence	Supported?	Latest release
	Preview (release notes)	This channel provides a preview of the next stable release. There may be breaking API changes between a given preview channel release and the next stable release.	At least one preview per stable version	No	1.7.0-preview1 (02/11/2025)
	Stable (release notes)	This channel is supported for use by apps in production environments. It includes only stable APIs.	No more frequent than every six months (+ servicing)	Yes	1.7.0 (1.7.250310001) (03/18/2025)
	Experimental (release notes)	This channel includes experimental features that are in early stages of development. Experimental features may be removed from the next release, or may never be released.	As needed when requiring feedback for features in early design or prototype stages	No	1.7.0-experimental3 (02/06/2025)

For a comprehensive list of all current and previous releases of the Windows App SDK, including download locations, see Downloads for the Windows App SDK.

Features available by release channel

The following table shows which features are currently available in each release channel.

Expand table

Feature	Stable	Preview	Experimental
Deployment guide for framework-dependent packaged apps	Available	Available	Available
Deployment guide for framework-dependent apps packaged with external location or unpackaged	Available	Available	Available
WinUI 3	Available	Available	Available
Text rendering	Available	Available	Available
Manage resources	Available	Available	Available
App lifecycle: App instancing	Available	Available	Available
App lifecycle: Rich activation	Available	Available	Available
App lifecycle: Power management	Available	Available	Available
Manage app windows	Available	Available	Available
Push notifications	Available	Available	Available
App notifications	Available	Available	Available
Windows Widgets	Available	Available	Available

Windows App SDK release servicing policy

The following policies define the servicing you can expect when you use a given Windows App SDK release.

Release lifecycle

The Windows App SDK has a lifecycle. A lifecycle begins when a version or service is released and ends when it's no longer supported. Knowing key dates in this release lifecycle helps you make informed decisions about when to upgrade or make other changes to your software.

Expand table

Windows App SDK version	Original release date	Latest patch version	Patch release date	Support level	End of servicing
1.7	03/18/2025	1.7.250310001	03/18/2025	Current	03/18/2026
1.6	09/04/2024	1.6.250205002	02/11/2025	Maintenance	09/04/2025
1.5	02/29/2024	1.5.250108004	01/15/2025	Out of Support	02/28/2025
1.4	08/29/2023	1.4.240802001	08/13/2024	Out of Support	08/29/2024
1.3	04/12/2023	1.3.230724000	07/25/2023	Out of Support	04/12/2024
1.2	11/10/2022	1.2.230313.1	03/15/2023	Out of Support	11/10/2023
1.1	05/24/2022	1.1.5	09/14/2022	Out of Support	05/24/2023
1.0	11/16/2021	1.0.4	06/14/2022	Out of Support	11/16/2022
0.8	6/24/2021	0.8.12	08/03/2022	Out of Support	6/24/2022
0.5	3/29/2021	0.5.9	8/10/2021	Out of Support	11/1/2021

Servicing

Customers can choose *Current* releases or *Maintenance* releases. Both types of releases receive critical fixes throughout their lifecycle, for security, compatibility, and reliability. You must stay up to date with the latest patches to qualify for support.

The quality of all releases is the same. The only difference is the servicing time frame.

Servicing for Current releases

Current releases are the latest stable release and they receive fixes more frequently. During the servicing period, Windows App SDK current release is updated to improve functional capabilities and mitigate security vulnerabilities.

Functional improvements are typically very targeted, and may address the following:

- Resolve reported crashes.
- Resolve severe performance issues.
- Resolve functional bugs in key scenarios.
- Add support for a new operating system versions

Servicing for Maintenance releases

Maintenance releases are no longer the latest stable release, but they will still receive critical fixes. The bar for fixes in Maintenance releases will be higher than the bar for fixes to the Current release.

After the maintenance period ends, the release is out of support.

Microsoft support for the Windows App SDK

The Windows App SDK is governed by the Microsoft Modern Lifecycle.

Although the Windows App SDK is currently backward compatible to Windows 10 version 1809, the Windows App SDK is supported by Microsoft only on the Windows releases still in support.

Support has two key benefits:

- Patches are provided for free, as required for functional or security issues.
- You can contact Microsoft support to request help, potentially at a cost.

Support is conditional on using the latest Windows App SDK patch update and a supported operating system.

End of support

End of support refers to the date when Microsoft no longer provides fixes, updates, or online technical assistance. End of support may also be referred to as 'end of life' or abbreviated 'EOL'. This is the time to make sure you have the latest available update installed.

Updates are cumulative, with each update built upon all of the updates that preceded it. A device needs to install the latest update to remain supported. Updates may include new features, fixes (security and/or non-security), or a combination of both. Not all features in an update will work on all devices. Update availability may vary, for example by country, region, network connectivity, or hardware capabilities (including, for example, free disk space).

Your use of out-of-support Windows App SDK versions may put your applications at risk. You are strongly recommended to not use out-of-support software.

How to get help

- The Windows App SDK uses GitHub Issues to track bugs and feature requests. Search the existing issues before filing new issues to avoid duplicates. For new issues, file your bug or feature request as a new issue.
- For help and questions about using the Windows App SDK, search for existing questions or post a new question on our GitHub Discussions page.
- Technical support for the use of the Windows App SDK may be available from Microsoft Customer Support Services (CSS). If you're a Premier or Unified Support customer, reach out to your account manager for further assistance. Otherwise, visit the Support For Business site to open a new support case for the Windows App SDK.

Latest stable channel release notes for the Windows App SDK

Article • 03/19/2025

The stable channel provides releases of the Windows App SDK that are supported for use by apps in production environments. Apps that use the stable release of the Windows App SDK can also be published to the Microsoft Store.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.

Stable channel release note archive:

- Stable channel release notes for the Windows App SDK 1.6
- Stable channel release notes for the Windows App SDK 1.5
- Stable channel release notes for the Windows App SDK 1.4
- Stable channel release notes for the Windows App SDK 1.3
- Stable channel release notes for the Windows App SDK 1.2
- Stable channel release notes for the Windows App SDK 1.1

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 1.7

The following sections describe new and updated features and known issues for version 1.7.

In an existing Windows App SDK app, you can update your Nuget package to 1.7.250310001 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Downloads for the Windows App SDK.

Version 1.7.0 (1.7.250310001)

New Badge Notifications Feature

The notification badge conveys a summary or status information specific to an app. This can be numeric (1-99) or a glyph from one of the system-provided glyphs. This new functionality provides an easy way for apps to show status, such as number of unread mails in a mail app or number of new posts in a social media app.

For more info, see GitHub #4926.

New CameraCaptureUI API

Developers have encountered challenges in the desktop environments due to WinRT CameraCaptureUI being dependent on CoreWindows, and lack of InitializeWithWindow support. The team has released this new `Microsoft.Windows.Media.Capture.CameraCaptureUI` API to WinAppSDK to provide a streamlined solution with feature parity, now supporting WindowID in the constructor for enhanced desktop compatibility.

For more info, see GitHub issue #4721.

New Authentication API

A new `OAuth2Manager` API provides a streamlined solution for web authentication, offering OAuth 2.0 capabilities with full feature parity across all Windows platforms supported by Windows App SDK. This new Authentication Manager is different from the public WebAuthentication Broker API, as it better aligns with OAuth best practices.

For more info, see GitHub issue #4772.

New Background Task support

Background tasks are app components that run in the background without a user interface, performing actions like download files, syncing data, sending notifications or

updating files. The new `BackgroundTaskBuilder` API provides WinAppSDK dependent apps the ability to directly register the full trust COM components with background tasks, removing the need to implement a workaround.

For more info, see GitHub #4831.

New TitleBar control

A new `TitleBar` control makes it much easier to create a great, customizable titlebar for your app. Configure properties such as the titlebar icon, Title, and Subtitle, include an integrated back button, or even add a custom control like a search box! The control includes robust titlebar capabilities like empty-space draggable regions, theme responsiveness, caption buttons, and built-in accessibility support so you can focus on your personalized design and still get the same reliable titlebar as the default experience.

For more info, see GitHub #10056.

Support for MathML

`RichEditBox` now supports MathML, via `RichEditTextDocument.SetMathMode` and `RichEditTextDocument.SetMathML`.

For more info, see GitHub #4196.

Enhanced Runtime

- Windows App SDK's Dynamic Dependencies APIs delegate all calls to Windows 11's implementation when running on >= Windows 11 24H2 (10.0.26100.0) providing improved performance and robustness. This holds true for all C/C++ (Mdd*()) and WinRT (namespace Microsoft.Windows.ApplicationModel.DynamicDependency) APIs.
  - Packaged processes calling Windows App SDK's Dynamic Dependencies APIs is now supported on >= Windows 11 24H2 (10.0.26100.0). This is still unsupported on older systems (WinAppSDK's implementation doesn't support packaged apps).
  - This has no impact to the developer experience. Callers can continue using the Bootstrapper API to add the WinAppSDK framework package to the calling process' package graph.
  - For more info, see GitHub PR #4949.

- Undocked Registration-free WinRT (URFW) is not enabled on >= Windows 11 24H2 (10.0.26100.0). The OS' implementation handles all Registration-free WinRT activity on these systems providing improved performance and robustness. For more info, see GitHub PR #4949.
- Detours is not used on >= Windows 11 24H2 (10.0.26100.0). Detours was only used by Windows App SDK's implementations of Dynamic Dependencies and Registration-free WinRT, but as those features are now handled by the OS' implementations there's no need for them to initialize or otherwise wire up Detours. This provides a small performance gain when loading Microsoft.WindowsAppRuntime.dll. For more info, see GitHub PR #4949.

New AppWindow APIs

New `AppWindow` APIs make it easier to control your app windows to create a great experience. New capabilities include using `SetTaskBarIcon` and `SetTitleBarIcon` to independently set the taskbar and titlebar icons, using `AppWindowTitleBar.PreferredTheme` to set the light/dark theme of the titlebar, and using new properties like `OverlappedPresenter.PreferredMinimumWidth` and `OverlappedPresenter.PreferredMaximumHeight` to set a minimum or maximum width or height for the window.

New Island APIs

The updates in the Microsoft.UI.Content namespace introduce several significant enhancements and new features aimed at improving the functionality and interoperability of the ContentIsland APIs. These changes are designed to support new hosting scenarios, enhance rendering capabilities, and ensure better synchronization of input and accessibility states. Key updates include:

1. New primitives for hosting ContentIslands:
    - `DesktopPopupSiteBridge`: Enables hosting a `ContentIsland` in the environment of a Win32 window with WS_POPUP style, facilitating scenarios where applications use popup windows for dialog boxes and message boxes.
    - `ChildSiteLink`: Allows a parent `ContentIsland` to host a nested child `ContentIsland`, providing a seamless partitioning of the rendering surface without user experience seams.
    - `DesktopAttachedSiteBridge`: Attaches to an existing Win32 window instead of creating a new one, designed to host a `ContentIsland` with

Windows.UI.Composition.Visuals at the root of the Win32 window hierarchy, ensuring full control over Win32-based input processing and accessibility.

2. Enhanced rendering and input synchronization:

    - The `LocalToParentTransformMatrix` and `ActualSize` properties of a `ChildSiteLink` are updated relative to the parent `ContentIsland` before rendering, avoiding latency and ensuring synchronized input and accessibility states.

3. ContentIslands with Windows.UI.Composition.Visuals:

    - `ContentIsland` can use Windows.UI.Composition.Visuals for rendering and Win32 window APIs for input processing, enabling interoperability with applications that use legacy UX frameworks. This allows for a gradual adoption of newer UX frameworks layered on top of the Windows App SDK Scene Graph, such as WinUI and React Native for Windows on Fabric. These updates collectively enhance the flexibility, performance, and interoperability of the ContentIsland APIs, enabling developers to create more sophisticated and responsive applications.

Additionally, the updates in the Microsoft.UI.Xaml namespace introduce a new `XamlIsland` API, which allows for the hosting of Xaml content within a SiteBridge or a `ChildSiteLink`. The `XamlIsland` offers greater flexibility compared to the `DesktopWindowXamlSource` API. While `DesktopWindowXamlSource` requires hosting within an existing Win32 window, the `XamlIsland` exposes a `ContentIsland`, enabling more options for hosting Xaml content.

Other notable changes

- New `RuntimeCompatibilityOptions` support will allow more control over how servicing changes affect apps. For more info, see GitHub #4966.
- A new `ReleaseInfo` API provides easy access to the version of the Windows App SDK Runtime in use. For more info, see GitHub #2893.
- Note: Windows Copilot Runtime APIs are not included this release. To experiment with these APIs, please continue to use the 1.7-experimental3 release and share your feedback!

New APIs for 1.7.0

This release includes the following new APIs compared to the stable 1.6 release:

```
```

```
Microsoft.Security.Authentication.OAuth

    AuthFailure
    AuthRequestParams
    AuthRequestResult
    AuthResponse
    ClientAuthentication
    CodeChallengeMethodKind
    OAuth2Manager
    TokenFailure
    TokenFailureKind
    TokenRequestParams
    TokenRequestResult
    TokenResponse
```

```
Microsoft.UI.Content

    ChildSiteLink
    ContentAutomationOptions
    ContentEnvironmentStateChangedEventArgs
        DidDisplayScaleChange

    ContentIsland
        AutomationOption
        Children
        CreateForSystemVisual
        FindAllForSystemCompositor
        FragmentRootAutomationProvider
        GetBySystemVisual
        LocalToClientTransformMatrix
        LocalToParentTransformMatrix
        NextSiblingAutomationProvider
        ParentAutomationProvider
        Popups
        PreviousSiblingAutomationProvider
        ProcessesKeyboardInput
        ProcessesPointerInput

    ContentIslandEnvironment
        DisplayScale

    ContentIslandStateChangedEventArgs
        DidLocalToClientTransformMatrixChange
        DidLocalToParentTransformMatrixChange

    ContentSite
        LocalToClientTransformMatrix
        LocalToParentTransformMatrix
        ProcessesKeyboardInput
        ProcessesPointerInput
```

```
    ContentSiteAutomationProviderRequestedEventArgs
    ContentSiteEnvironment
        DisplayScale

    ContentSiteEnvironmentView
        DisplayScale

    ContentSiteView
        AutomationOption
        LocalToClientTransformMatrix
        LocalToParentTransformMatrix
        ProcessesKeyboardInput
        ProcessesPointerInput

    DesktopAttachedSiteBridge
    DesktopChildSiteBridge
        CreateWithDispatcherQueue

    DesktopPopupSiteBridge
    IContentSiteAutomation
    IContentSiteInput
    IContentSiteLink
```

```
Microsoft.UI.Input

    InputFocusNavigationHost
        GetForSiteLink
```

```
Microsoft.UI.Text

    RichEditTextDocument
        GetMathML
        GetMathMode
        SetMathML
        SetMathMode
```

```
Microsoft.UI.Windowing

    AppWindow
        SetTaskbarIcon
        SetTaskbarIcon
        SetTitleBarIcon
        SetTitleBarIcon
```

```
    AppWindowTitleBar
        PreferredTheme

    OverlappedPresenter
        PreferredMaximumHeight
        PreferredMaximumWidth
        PreferredMinimumHeight
        PreferredMinimumWidth

    TitleBarTheme
```

```
Microsoft.UI.Xaml

    XamlIsland
    XamlRoot
        ContentIsland
```

```
Microsoft.UI.Xaml.Controls

    TitleBar
    TitleBarAutomationPeer
    TitleBarTemplateSettings
```

```
Microsoft.Windows.ApplicationModel.Background

    BackgroundTaskBuilder
```

```
Microsoft.Windows.ApplicationModel.Background.UniversalBGTask

    Task
```

```
Microsoft.Windows.ApplicationModel.WindowsAppRuntime

    ReleaseInfo
    RuntimeCompatibilityChange
    RuntimeCompatibilityOptions
```

```
    RuntimeInfo
    WindowsAppRuntimeVersion
```

```
Microsoft.Windows.BadgeNotifications

    BadgeNotificationGlyph
    BadgeNotificationManager
```

```
Microsoft.Windows.Media.Capture

    CameraCaptureUI
    CameraCaptureUIMaxPhotoResolution
    CameraCaptureUIMaxVideoResolution
    CameraCaptureUIMode
    CameraCaptureUIPhotoCaptureSettings
    CameraCaptureUIPhotoFormat
    CameraCaptureUIVideoCaptureSettings
    CameraCaptureUIVideoFormat
```

Bug fixes

This release includes the following bug fixes:

- Changed `SplitButton` so touch input now matches the behavior of mouse input. For more info, see GitHub issue #178.
- Changed cascading menus so sub menus now open immediately if clicked. For more info, see GitHub issue #939.
- Fixed an issue where opening a `ComboBox` which is in a flyout closes all flyouts. For more info, see GitHub issue #1467.
- Fixed an issue where `SwipeControl` would randomly crash in a `ListView`. For more info, see GitHub issue #2527.
- Fixed an issue where drag-and-drop only a `ListViewItem` would leave it in the wrong visual state. For more info, see GitHub issue #3458.
- Fixed an issue in `StackLayout` so that it respects the ItemsRepeater.HorizontalAlignment and ItemsRepeater.VerticalAlignment properties (when StackLayout.Orientation is Vertical and Horizontal respectively). The old layout behaved as if the ItemsRepeater alignment was Stretch. With the fix, the layout results in items aligned to the right when the Right alignment is used, for example. For more info, see GitHub issue #3842.

- Fixed a potential crash when using a resource which contains an `x:Bind`. For more info, see GitHub issue #5786.
- Fixed an issue where deleting items in the `ItemsRepeater`'s source would not generate items which moved up into view. For more info, see GitHub issue #6661.
- Fixed an issue where the right Alt key would not show keytips for Access Keys. For more info, see GitHub issue #8447. **Note:** This may result in key events for the right Alt key no longer being delivered to handles in the app or controls.
- Fixed an issue where using a ResourceDictionary containing only a single resource would fail to find that resource and likely cause a crash. For more info, see GitHub issue #8832.
- Fixed a crash where `UniformGridLayout` would sometimes pick a wrong layout anchor and cause infinite layout passes when scrolling backwards. For more info, see GitHub issue #9199.
- Fixed an issue where setting `NavigationFailedEventArgs.Handled` to True would still throw an exception. For more info, see GitHub issue #9632.
- Fixed an issue where `TabView` would not apply any specified `CornerRadius`. For more info, see GitHub issue #9846.
- Fixed a potential layout cycle crash in `StackLayout`. For more info, see GitHub issue #9852.
- Fixed a potential crash in `ItemsView` when removing items. For more info, see GitHub issue #9868.
- Fixed an issue in 1.7-preview1 where popups no longer correctly moved with their parent window. For more info, see GitHub issue #10386.
- Based on feedback from 1.7-preview1, renamed some properties on the new `TitleBar` control.

Latest preview channel release notes for the Windows App SDK

Article • 02/12/2025

> **ⓘ Important**
>
> The preview channel is **not supported** for use in production environments, and apps that use the preview releases cannot be published to the Microsoft Store.

The preview channel includes releases of the Windows App SDK with preview channel features in late stages of development. Preview releases do not include experimental features and APIs but may still be subject to breaking changes before the next stable release.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on preview releases, see Install tools for preview and experimental channels of the Windows App SDK.

Preview channel release note archive:

- Preview channel release notes for the Windows App SDK 1.6
- Preview channel release notes for the Windows App SDK 1.5
- Preview channel release notes for the Windows App SDK 1.4
- Preview channel release notes for the Windows App SDK 1.3
- Preview channel release notes for the Windows App SDK 1.2
- Preview channel release notes for the Windows App SDK 1.1
- Preview channel release notes for the Windows App SDK 1.0

Version 1.7 Preview 1 (1.7-preview1)

This is the latest release of the preview channel for version 1.7.

In an existing Windows App SDK 1.6 (from the stable channel) app, you can update your Nuget package to 1.7.0-preview1 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Downloads for the Windows App SDK.

New features

New Badge Notifications Feature

New badge notification support allows showing a number or glyph badge on your app in the taskbar. For more info, see GitHub #4926.

New CameraCaptureUI API

A new CameraCaptureUI API makes it easier to capture photos and videos in your Windows App SDK app. For more info, see GitHub issue #4721.

New Authentication API

A new `OAuth2Manager` API provides a streamlined solution for web authentication, offering OAuth 2.0 capabilities with full feature parity across all Windows platforms supported by Windows App SDK. For more info, see GitHub issue #4772.

New Background Task support

A new `BackgroundTaskBuilder` API enables registering background tasks for Windows App SDK apps. For more info, see GitHub #4831.

New TitleBar control

A new `TitleBar` control makes it much easier to create a great, customizable titlebar for your app. Configure properties such as the titlebar icon, Title, and Subtitle, include an integrated back button, or even add a custom control like a search box! The control includes robust titlebar capabilities like empty-space draggable regions, theme responsiveness, caption buttons, and built-in accessibility support so you can focus on your personalized design and still get the same reliable titlebar as the default experience. For more info, see GitHub #10056.

Support for MathML

`RichEditBox` now supports MathML, via `RichEditTextDocument.SetMathMode` and `RichEditTextDocument.SetMathML`. For more info, see GitHub #4196.

Other notable changes

- New `RuntimeCompatibilityOptions` support will allow more control over how servicing changes affect apps. For more info, see GitHub #4966.
- A new `ReleaseInfo` API provides easy access to the version of the Windows App SDK Runtime in use. For more info, see GitHub #2893.
- Note: Windows Copilot Runtime APIs are not included this release. To experiment with these APIs, please continue to use the 1.7-experimental3 release and share your feedback!
- Note: New APIs for windowing on `AppWindow` are not included in this release. To experiment with these APIs, please continue to use the 1.7-experimental3 release and share your feedback!

New APIs

This release includes the following new APIs compared to the stable 1.6 release:

```
Microsoft.Security.Authentication.OAuth

    AuthFailure
    AuthRequestParams
    AuthRequestResult
    AuthResponse
    ClientAuthentication
    CodeChallengeMethodKind
    OAuth2Manager
    OAuthContract
    TokenFailure
    TokenFailureKind
    TokenRequestParams
    TokenRequestResult
    TokenResponse
```

```
Microsoft.UI.Text

    RichEditTextDocument
        GetMathML
        GetMathMode
        SetMathML
        SetMathMode

    TextApiContract
```

```
Microsoft.UI.Xaml

    XamlIsland
    XamlRoot
        ContentIsland
```

```
Microsoft.UI.Xaml.Controls

    TitleBar

Bug fixes

This release includes the following bug fixes:

- Changed `SplitButton` so touch input now matches the behavior of mouse input. For more info, see GitHub issue #178.
- Changed cascading menus so sub menus now open immediately if clicked. For more info, see GitHub issue #939.
- Fixed an issue where opening a `ComboBox` which is in a flyout closes all flyouts. For more info, see GitHub issue #1467.
- Fixed an issue where `SwipeControl` would randomly crash in a `ListView`. For more info, see GitHub issue #2527.
- Fixed an issue where drag-and-drop only a `ListViewItem` would leave it in the wrong visual state. For more info, see GitHub issue #3458.
- Fixed an issue in `StackLayout` so that it respects the ItemsRepeater.HorizontalAlignment and ItemsRepeater.VerticalAlignment properties (when StackLayout.Orientation is Vertical and Horizontal respectively). The old layout behaved as if the ItemsRepeater alignment was Stretch. With the fix, the layout results in items aligned to the right when the Right alignment is used, for example. For more info, see GitHub issue #3842.
- Fixed an issue where deleting items in the `ItemsRepeater`'s source would not generate items which moved up into view. For more info, see GitHub issue #6661.
- Fixed an issue where the right Alt key would not show keytips for Access Keys. For more info, see GitHub issue #8447. **Note:** This may result in key events for the right Alt key no longer being delivered to handles in the app or controls.

- Fixed a crash where `UniformGridLayout` would sometimes pick a wrong layout anchor and cause infinite layout passes when scrolling backwards. For more info, see GitHub issue #9199.
- Fixed an issue where setting `NavigationFailedEventArgs.Handled` to True would still throw an exception. For more info, see GitHub issue #9632.
- Fixed an issue where `TabView` would not apply any specified `CornerRadius`. For more info, see GitHub issue #9846.
- Fixed a potential layout cycle crash in `StackLayout`. For more info, see GitHub issue #9852.
- Fixed a potential crash in `ItemsView` when removing items. For more info, see GitHub issue #9868.

Latest experimental channel release notes for the Windows App SDK

Article • 02/06/2025

> **ⓘ Important**
>
> The experimental channel is **not supported** for use in production environments, and apps that use the experimental releases cannot be published to the Microsoft Store.

The experimental channel includes releases of the Windows App SDK with experimental channel features in early stages of development. APIs for experimental features have the Experimental attribute. If you call an experimental API in your code, you will receive a build-time warning. All APIs in the experimental channel are subject to extensive revisions and breaking changes. Experimental features and APIs may be removed from subsequent releases at any time.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on experimental releases, see Install tools for preview and experimental channels of the Windows App SDK.

Version 1.7 Experimental (1.7.0-experimental3)

Use on-device AI with Windows Copilot Runtime APIs

> **ⓘ Important**
>
> The underlying ML models required for these APIs currently require your device to be running the latest Windows 11 Insider Preview Build on the Dev Channel. Additionally, these APIs require your device to be a Copilot+ PC. See **Copilot+ PCs Developer Guide** to learn more about these devices. APIs will throw an exception when called on devices lacking the necessary support.

The Windows Copilot Runtime (WCR) offers several AI-powered features and APIs for you to easily, efficiently, and responsibly use on-device AI models in your Windows apps. In this release we are making available several scenario focused APIs for you to leverage powerful capabilities without the need to find, run, or optimize your own Machine Learning (ML) models.

Learn more about responsible development practices used during WCR API development that you can also apply as you create AI-assisted features in the Developing Responsible Generative AI Applications and Features on Windows guidance.

Phi Silica

With **Phi Silica**, Microsoft's most powerful NPU-tuned local language model, you can generate text responses to broad user prompts with built in content moderation. You can also specify it to perform common tasks like summarizing a piece of text, rewriting a piece of text for clarity, and converting text to a table format. Phi Silica is optimized for efficiency and performance on Windows Copilot+ PCs devices while still offering many of the capabilities found in Large Language Models (LLMs).

See Get started with Phi Silica in the Windows App SDK and API ref for Phi Silica in the Windows App SDK for more information.

Text Recognition (OCR)

Text recognition, also known as optical character recognition (OCR), APIs in Windows Copilot Runtime (WCR) can detect and extract text within images and convert it into machine readable character streams. These APIs can identify characters, words, lines, polygonal text boundaries, and provide confidence levels for each match. The set of WCR AI-assisted APIs benefit from NPU-assisted acceleration to perform faster and more accurately than the legacy Windows.Media.Ocr.OcrEngine APIs.

See Get Started with Text Recognition (OCR) in the Windows App SDK and API ref for AI-backed Text Recognition (OCR) in the Windows App SDK for more information.

Image Super Resolution

Using the 'ImageScaler' APIs you can increase the sharpness and clarity of an image and upscale the image up to 8x its original resolution.

See What can I do with Image Super Resolution? and API ref for AI imaging features in the Windows App SDK to get started.

Image Description

The Image Description APIs can be used to generate a text description of an image. The APIs are configurable to specify the length and type of the text description. Image descriptions may include a short caption or a long description for users with accessibility needs.

> **Note**
>
> When calling ImageDescriptionGenerator.DescribeAsync() in a Debug build, an error may occur that can be mitigated by continuing the build in Visual Studio.

See What can I do with Image Description? and API ref for AI imaging features in the Windows App SDK to learn more.

Image Segmentation

Using Image Segmentation APIs you can identify specific objects within an image. The model takes both an image and a "hints" object and returns a mask of the identified object.

See What can I do with Image Segmentation? and API ref for AI imaging features in the Windows App SDK to get started.

New APIs for Windowing

New `AppWindow` APIs make it easier to control your app windows and create a great experience. New capabilities include using `EnablePlacementPersistence` to automatically remember the size and position of your windows, using `SetTaskBarIcon` and `SetTitleBarIcon` to independently set the taskbar and titlebar icons, using `AppWindowTitleBar.PreferredTheme` to set the light/dark theme of the titlebar, and using `OverlappedPresenter.PreferredMinimum/MaximumSize` to set a minimum or maximum size for the window.

Other notable changes

- The missing C# projections for the new `BadgeNotifications` have been added so these APIs are now usable from C#.
- A class registration issue which prevented using the new `AppNotificationConferencingConfig` API has been fixed. Note that this enhanced user experience for video or audio calling in notifications is only available on the latest Windows Insider releases of Windows.

New APIs

This release includes the following new and modified experimental APIs compared to 1.7-experimental2:

```
Microsoft.Graphics.Imaging

    ImageBuffer
    ImageBufferContract
    ImageObjectExtractor
    ImageObjectExtractorContract
    ImageObjectExtractorHint
    ImageScaler

    WorkloadsContract
```

Version 1.7 Experimental (1.7.0-experimental2)

Background Task Registration

A new `BackgroundTaskBuilder` API enables registering background tasks for Windows App SDK apps. For more info, see GitHub #4831.

New Notifications Features

New badge notification support allows showing a number or glyph badge on your app in the taskbar. For more info, see GitHub #4926.

> **Important**
>
> In this release, the C# projections are missing for the new `BadgeNotifications` APIs, which prevents using them from C#. The APIs are available in C++.

Video or audio calling can have an enhanced user experience in notifications. For more info, see GitHub #4783.

> **Important**
>
> This functionality is only available on the latest Windows Insider releases of Windows.

Other notable changes

- `RichEditBox` now supports math mode, via `RichEditTextDocument.SetMathMode` and `RichEditTextDocument.SetMath`.
- New `CompatibilityOptions` support will allow more control over how servicing changes affect apps. For more info, see GitHub #4976.

New APIs

This release includes the following new and modified experimental APIs:

```
Microsoft.Security.Authentication.OAuth

    AuthFailure
    AuthRequestParams
    AuthRequestResult
    AuthResponse
    ClientAuthentication
    CodeChallengeMethodKind
```

```

Version 1.7 Experimental (1.7.0-experimental1)

This is the latest release of the experimental channel.

To download, retarget your WinAppSDK NuGet version to `1.7.241114004-experimental1`.

New CameraCaptureUI API

A new CameraCaptureUI API makes it easier to capture photos and videos in your WinAppSDK app. For more info, see GitHub issue #4721.

New Authentication API

A new `OAuth2Manager` API provides a streamlined solution for web authentication, offering OAuth 2.0 capabilities with full feature parity across all Windows platforms supported by WinAppSDK. For more info, see GitHub issue #4772.

New Background Task support

A new `BackgroundTaskBuilder` API brings integrated support for background task registration to your WinAppSDK apps. For more info, see GitHub issue #4822.

New APIs for 1.7-experimental1

This release includes the following new and modified experimental APIs:

C#

```
Microsoft.Security.Authentication.OAuth

    AuthFailure
    AuthRequestParams
    AuthRequestResult
    AuthResponse
    ClientAuthentication
    CodeChallengeMethodKind
```

```
    OAuth2Manager

Bug fixes

This release includes the following bug fixes:

- Changed `SplitButton` so touch input now matches the behavior of mouse input. For more info, see GitHub issue #178.
- Changed cascading menus so sub menus now open immediately if clicked. For more info, see GitHub issue #939.
- Fixed an issue where opening a `ComboBox` which is in a flyout closes all flyouts. For more info, see GitHub issue #1467.
- Fixed an issue where `SwipeControl` would randomly crash in a `ListView`. For more info, see GitHub issue #2527.
- Fixed an issue where drag-and-drop only a `ListViewItem` would leave it in the wrong visual state. For more info, see GitHub issue #3458.
- Fixed an issue in `StackLayout` so that it respects the ItemsRepeater.HorizontalAlignment and ItemsRepeater.VerticalAlignment properties (when StackLayout.Orientation is Vertical and Horizontal respectively). The old layout behaved as if the ItemsRepeater alignment was Stretch. With the fix, the layout results in items aligned to the right when the Right alignment is used, for example. For more info, see GitHub issue #3842.
- Fixed an issue where deleting items in the `ItemsRepeater`'s source would not generate items which moved up into view. For more info, see GitHub issue #6661.
- Fixed an issue where the right Alt key would not show keytips for Access Keys. For more info, see GitHub issue #8447. **Note:** This may result in key events for the right Alt key no longer being delivered to handles in the app or controls.
- Fixed a crash where `UniformGridLayout` would sometimes pick a wrong layout anchor and cause infinite layout passes when scrolling backwards. For more info, see GitHub issue #9199.
- Fixed an issue where setting `NavigationFailedEventArgs.Handled` to True would still throw an exception. For more info, see GitHub issue #9632.
- Fixed an issue where `TabView` would not apply any specified `CornerRadius`. For more info, see GitHub issue #9846.
- Fixed a potential layout cycle crash in `StackLayout`. For more info, see GitHub issue #9852.
- Fixed a potential crash in `ItemsView` when removing items. For more info, see GitHub issue #9868.

Stable channel release notes for the Windows App SDK 1.6

Article • 03/19/2025

The stable channel provides releases of the Windows App SDK that are supported for use by apps in production environments. Apps that use the stable release of the Windows App SDK can also be published to the Microsoft Store.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 1.6.6 (1.6.250228001)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.6 release.

- Fixed an issue where a child window posting WM_NCMOUSELEAVE to the parent window would result in a loop that blocks new mouse input events.
- Fixed a crash which would occur on the next AppWindow.Changed event after a WebView2 process failure.
- Fixed a potential crash when using an Accessibility tool and closing a window.
- Fixed an issue where a textbox would not accept key input if given focus by clicking in the area of the clear button of the textbox. For more info, see GitHub issue #7703.

- Fixed an issue where a tooltip is not shown for the Minimize button in the titlebar when using `ExtendsContentIntoTitleBar=true`. For more info, see GitHub issue #9149.

This release includes the following new APIs:

A new `IsPlaceholderContent` property on `WidgetInfo` and `WidgetUpdateRequestOptions` enables a Widget provider to indicate that it would display placeholder content if rendered. For example, a Widget that shows weather information should set IsPlaceholderContent to true if the user has not yet specified a weather location and the Widget is merely showing weather information for a default location like Seattle. When a Widget is marked as placeholder, certain hosts may decide to hide the Widget or prioritize other Widgets.

```
Microsoft.Windows.Widgets.Providers

    WidgetInfo
        IsPlaceholderContent

    WidgetUpdateRequestOptions
        IsPlaceholderContent
```

Version 1.6.5 (1.6.250205002)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.6 release.

- Fixed several memory leak issues.

Version 1.6.4 (1.6.250108002)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.6 release.

- Fixed an issue with text selection highlighting in a multi-line TextBox. For more info, see GitHub issue #9965.
- Fixed an issue where the DDLM package would sometimes not install, preventing launch of unpackaged apps. For more info, see GitHub issue #3855.
- Fixed a potential crash in Detours in some scenarios. For more info, see GitHub issue #4937.

- Fixed another potential issue where a menu off a CommandBar may incorrectly open up instead of down when the CommandBar is at the bottom of the window.
- Fixed a potential crash when running on older graphics hardware.
- Fixed a potential crash in pointer event handling when closing a window.
- Fixed a potential crash caused by `CUIAWindow::InitIds` sometimes triggering reentrancy.
- Fixed a potential crash when using `CompositionCapabilities.Changed` event.
- Fixed an issue with some Unicode characters displaying as squares in TextBox/RichEditBox.
- Fixed `PackageDeploymentManager.EnsurePackage*Async()` handling of `options.RegisterNewerIfAvailable`. For more info, see GitHub issue #4864.

Version 1.6.3 (1.6.241114003)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.6 release.

- Fixed an issue where reading the `AppWindow.ExtendsContentIntoTitleBar` property turns on custom titlebar rendering. For more info, see GitHub issue #9988.
- Fixed a potential crash during destruction of a `TextBox`/`RichEditBox`. For more info, see GitHub issue #9070.
- Fixed an issue where `PackageDeploymentManager.IsPackageReadyOrNewerAvailable()` failed. For more info, see GitHub issue #4817.
- Fixed an issue where `ScrollViewer` would leak.
- Added detection for a rare scenario where the app stops rendering and never recovers.
- Fixed an issue where `PackageDeploymentManager.RegisterPackageSetAsync()` requires URI when it should be optional to register by PackageFamilyName.
- Fixed an issue that prevented apps from being installed or uninstalled. For more info, see GitHub issue #4881.

This release includes the following new APIs which allow for providers of Widgets to incorporate web content in their Widgets:

```
C#

Microsoft.Windows.Widgets.Providers
  IWidgetManager2
  IWidgetProviderMessage
  IWidgetResourceProvider
  WidgetManager
     SendMessageToContent
```

```
WidgetMessageReceivedArgs
WidgetResourceRequest
WidgetResourceRequestedArgs
WidgetResourceResponse
```

Version 1.6.1 (1.6.240923002)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.6 release.

- Fixed a crash when using FocusVisualKind.Reveal(). For more info, see GitHub issue #9966.
- Fixed noisy C++ exceptions from Bcp47Langs.dll. For more info, see GitHub issue #4691. Note that this fix removes the synchronization with `Windows.Globalization.ApplicationLanguages.PrimaryLanguageOverride`.
- Fixed an issue where an extra `Unloaded` event was raised immediately after showing a `ContentDialog`. For more info, see GitHub issue #8402.
- Fixed an issue where a CommandBar menu might have incorrectly opened up even when there was room for it to open down.
- Fixed some issues where input to `InputNonClientPointerSource` regions was not handled correctly when the top-level window was running in right-to-left mode.
- Fixed the compile-time check for the Windows SDK framework version to handle the slightly different framework name used for .NET 9.

Version 1.6

The following sections describe new and updated features and known issues for version 1.6.

In an existing Windows App SDK 1.5 app, you can update your Nuget package to 1.6.240829007 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Downloads for the Windows App SDK.

Required project changes for 1.6

C++ project changes

When updating a C++ project to 1.6, you'll need to add a project reference to the `Microsoft.Web.WebView2` package. If you update via NuGet Package Manager in Visual

Studio, this dependency will be added for you.

C# project changes

In 1.6, Windows App SDK managed apps require Microsoft.Windows.SDK.NET.Ref `*.*.*.38` or later, which can be specified via WindowsSdkPackageVersion in your `csproj` file. For example:

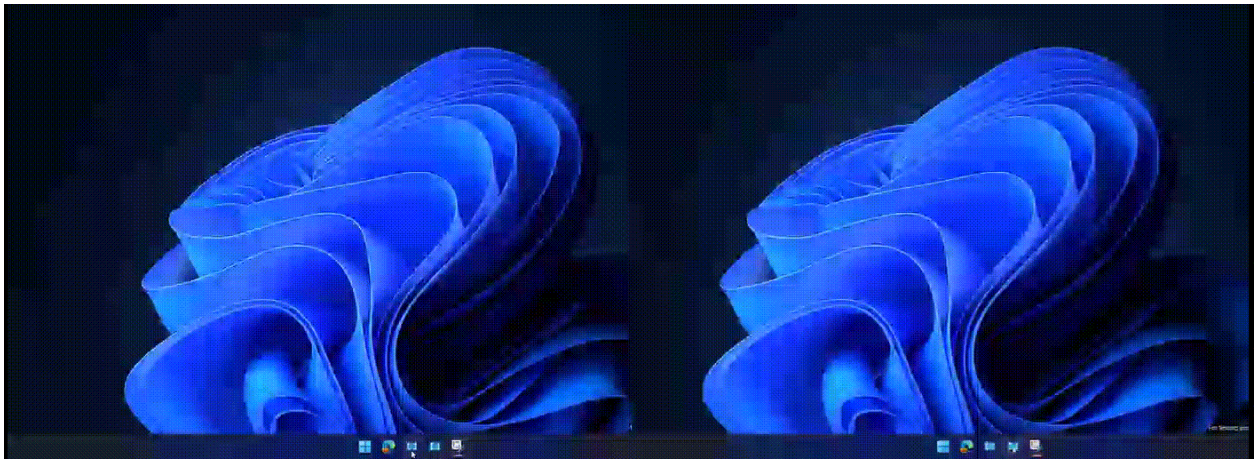
XML

```
<Project Sdk="Microsoft.NET.Sdk">
   <PropertyGroup>
       <OutputType>WinExe</OutputType>
       <TargetFramework>net8.0-windows10.0.22621.0</TargetFramework>
       <TargetPlatformMinVersion>10.0.17763.0</TargetPlatformMinVersion>
       <WindowsSdkPackageVersion>10.0.22621.38</WindowsSdkPackageVersion>
   <PropertyGroup>
   ...
```

In addition, Windows App SDK managed apps should update to Microsoft.Windows.CsWinRT `2.1.1` (or later).

> **Note**
>
> These manual references will no longer be needed once the next .NET SDK servicing update is released.

Native AOT support



The .NET `PublishAot` project property is now supported for native Ahead-Of-Time compilation. For details on Native AOT, see Native AOT Deployment. Because AOT builds

on Trimming support, much of the following trimming-related guidance applies to AOT as well.

For `PublishAot` support and trimming support, in addition to the C# project changes described in the previous section you'll also need a package reference to Microsoft.Windows.CsWinRT `2.1.1` (or later) to enable the source generator from that package until the next .NET SDK servicing update is released when it will no longer be required.

For more info, see the CsWinRT Trimming / AOT support doc and the CsWinRT 2.1.1 Release Notes.

Because the Windows App SDK invokes publishing targets when F5 deploying, we recommend enabling `PublishAot` at NuGet restore time by adding this to your `csproj` file:

```xml
<PublishAot>true</PublishAot>
```

Resolving AOT Issues

In this release, the developer is responsible for ensuring that all types are properly rooted to avoid trimming (such as with reflection-based `{Binding}` targets). Later releases will enhance both C#/WinRT and the XAML Compiler to automate rooting where possible, alert developers to trimming risks, and provide mechanisms to resolve.

Partial Classes

C#/WinRT also includes `PublishAot` support in version 2.1.1. To enable a class for AOT publishing with C#/WinRT, it must first be marked `partial`. This allows the C#/WinRT AOT source analyzer to attribute the classes for static analysis. Only classes (which contain methods, the targets of trimming) require this attribute.

Unsafe Code Error

The CsWinRT source generator might generate code that makes use of `unsafe`. If you hit such an error during compilation or a diagnostic warning for it (CS0227 for "Unsafe code may only appear if compiling with /unsafe"), you should set EnableUnsafeBlocks to true. For more info, see GitHub issue CsWinRT #1721.

WebView2 not yet AOT compatible

The WebView2 projections in `Microsoft.Web.WebView2` package version 1.0.2651.64 are not yet AOT compatible. This will be fixed in an upcoming release of the `Microsoft.Web.WebView2` package, which you can then reference in your project.

Reflection-Free Techniques

To enable AOT compatibility, reflection-based techniques should be replaced with statically typed serialization, AppContext.BaseDirectory, typeof(), etc. For details, see Introduction to trim warnings.

Rooting Types

Until full support for `{Binding}` is implemented, types may be preserved from trimming as follows:

Given project `P` consuming assembly `A` with type `T` in namespace `N`, which is only dynamically referenced (so normally trimmed), `T` can be preserved via:

`P.csproj`:

XML

```xml
<ItemGroup>
    <TrimmerRootDescriptor Include="ILLink.Descriptors.xml" />
</ItemGroup>
```

`ILLink.Descriptors.xml`:

XML

```xml
<?xml version="1.0" encoding="utf-8"?>
<linker>
    <assembly fullname="A">
        <type fullname="N.T" preserve="all" />
    </assembly>
</linker>
```

For complete root descriptor XML expression syntax, see Root Descriptors.

> ⓘ Note

Dependency packages that have not yet adopted AOT support may exhibit runtime issues.

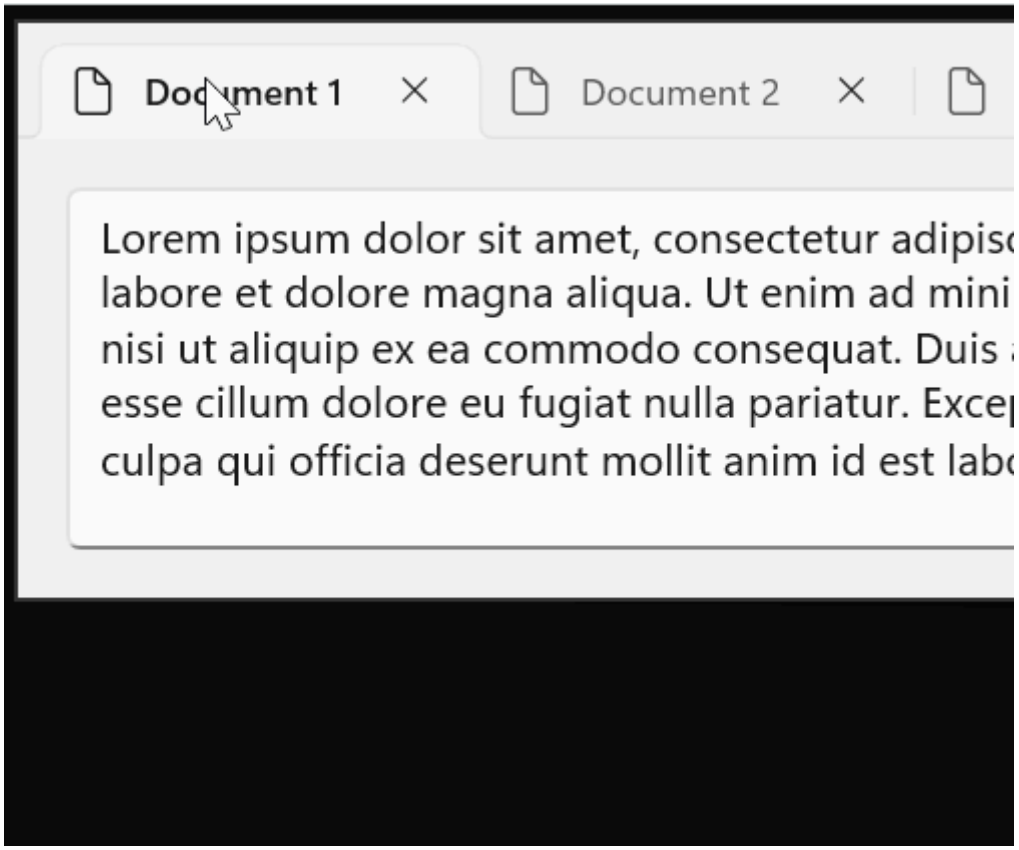
Decoupled WebView2 versioning

The Windows App SDK now consumes the Edge WebView2 SDK as a NuGet reference rather than embedding a hardcoded version of the Edge WebView2 SDK. The new model allows apps to choose a newer version of the `Microsoft.Web.WebView2` package instead of being limited to the version with which the Windows App SDK was built. The new model also allows apps to reference NuGet packages which also reference the Edge WebView2 SDK. For more info, see GitHub issue #5689.

New Package Deployment APIs

The Package Management API has received several enhancements including Is*ReadyOrNewerAvailable*(), EnsureReadyOptions.RegisterNewerIfAvailable, Is*Provisioned*(), IsPackageRegistrationPending(), and several bug fixes. See PackageManagement.md and Pull Request #4453 for more details.

Improved TabView tab tear-out



`TabView` supports a new `CanTearOutTabs` mode which provides an enhanced experience for dragging tabs and dragging out to a new window. When this new option is enabled, tab dragging is very much like the tab drag experience in Edge and Chrome where a new window is immediately created during the drag, allowing the user to drag it to the edge of the screen to maximize or snap the window in one smooth motion. This implementation also doesn't use drag-and-drop APIs, so it isn't impacted by any limitations in those APIs. Notably, tab tear-out is supported in processes running elevated as Administrator.

Other notable changes

- Added a new `ColorHelper.ToDisplayName()` API, filling that gap from UWP.
- Added a new `Microsoft.Windows.Globalization.ApplicationLanguages` class, which notably includes a new `PrimaryLanguageOverride` feature. For more info, see GitHub issue #4523.
- Unsealed `ItemsWrapGrid`. This should be a backward-compatible change.
- `PipsPager` supports a new mode where it can wrap between the first and last items.

- `RatingControl` is now more customizable, by moving some hard-coded style properties to theme resources. This allows apps to override these values to better customize the appearance of RatingControl.

- WinUI 3 has changed to the typographic model for font selection rather than the legacy weight/stretch/style model. The typographic model is required for some newer fonts, including Segoe UI Variable, and enables enhanced font capabilities. Some older fonts which rely on the weight/stretch/style model for selection may not be found with the typographic model.

Known Issues

- If the debugger is set to break on all C++ exceptions, it will break on some noisy exceptions on start-up in the BCP47 (Windows Globalization) code. For more info, see GitHub issue #4691.
- Component library packages which reference the WinAppSDK 1.6 package will not correctly get the referenced WebView2 package contents. For more info, see WebView2Feedback #4743. A workaround is to add a direct reference to the `Microsoft.Web.WebView2` package where needed.
- Apps compiled with Native AOT might sometimes experience a hanging issue after page navigation due to a race condition in the .NET runtime's GC thread. For more info, see .NET issue #104582.
- The initial release of 1.6.0 introduced an issue with one of our dependencies that we expect will be resolved in an upcoming release of the .NET SDK. If you experience an error with the version of your Microsoft.Windows.SDK.NET reference, you'll need to explicitly reference the version of the .NET SDK that is specified by your error message. For example, if the error says you need version 10.0.19041.38, add the following to your `.csproj` file:
  - `<WindowsSdkPackageVersion>10.0.19041.38</WindowsSdkPackageVersion>`.

Bug Fixes

- Fixed a crash when setting `InfoBar.IsOpen` in .xaml. For more info, see GitHub issue #8391.
- Fixed an issue where HTML elements would lose pointer capture when the mouse moved outside of the `WebView2` bounds. For more info, see GitHub issue #8677.
- Fixed an issue where drag and drop into a flyout with `ShouldConstrainToRootBounds=false` did not work. For more info, see GitHub issue #9276.
- Fixed an issue where `ms-appx://` references did not work when `PublishSingleFile` is enabled. For more info, see GitHub issue #9468.
- Fixed an issue where debugger symbols weren't working correctly for some binaries. For more info, see GitHub issue #4633.
- Fixed a potential crash when subclassing `NavigationView`.
- Fixed an issue where table borders in a `RichEditBox` would not correctly erase when scrolling or reducing the size of the table.
- Fixed an issue where flyouts from `MediaTransportControls` had a fully transparent background.
- Fixed an issue where dragging into a WebView2 would fail or drop in the wrong location on display scale factors other than 100% or when system text scaling is enabled.

- Fixed an issue where `TextBox`/`RichEditBox` would not announce to Accessibility tools when input is blocked due to being at the `MaxLength` limit.
- Fixed a few issues around handling of custom titlebar scenarios. For more info, see GitHub issues #7629, #9670, #9709 and #8431.
- Fixed an issue where `InfoBadge` icon was not visible. For more info, see GitHub issue #8176.
- Fixed an issue with icons sometimes showing in the wrong position in `CommandBarFlyout`. For more info, see GitHub issue #9409.
- Fixed an issue with keyboard focus in menus when opening or closing a sub menu. For more info, see GitHub issue #9519.
- Fixed an issue with `TreeView` using the incorrect `IsExpanded` state when recycling items. For more info, see GitHub issue #9549.
- Fixed an issue when using an ElementName binding in an `ItemsRepeater.ItemTemplate`. For more info, see GitHub issue #9715.
- Fixed an issue with the first item in an `ItemsRepeater` sometimes having an incorrect position. For more info, see GitHub issue #9743.
- Fixed an issue with `InputNonClientPointerSource` sometimes breaking input to the min/max/close buttons. For more info, see GitHub issue #9749.
- Fixed a compile error when using Microsoft.UI.Interop.h with clang-cl. For more info, see GitHub issue #9771.
- Fixed an issue where the `CharacterReceived` event was not working in `ComboBox`/`TextBox`. For more info, see GitHub issue #9786.
- Fixed an issue where duplicate `KeyUp` events were raised for arrow and tab keys. For more info, see GitHub issue #9399.
- Fixed an issue where the `PowerManager.SystemSuspendStatusChanged` event was unusable to get the `SystemSuspendStatus`. For more info, see GitHub issue #2833.
- Fixed an issue where initial keyboard focus was not correctly given to a `WebView2` when that was the only control in the window.
- Fixed an issue when using `ExtendsContentIntoTitleBar=true` where the Min/Max/Close buttons did not correctly appear in the UI Automation, which prevented Voice Access from showing numbers for those buttons.
- Fixed an issue where an app might crash in a lock check due to unexpected reentrancy.
- Fixed an issue where `Hyperlink` colors did not correctly update when switching into a high contrast theme.
- Fixed an issue where changing the collection of a `ListView` in a background window may incorrectly move that window to the foreground and take focus.

- Fixed an issue where calling `ItemsRepeater.StartBringIntoView` could sometimes cause items to disappear.
- Fixed an issue where touching and dragging on a `Button` in a `ScrollViewer` would leave it in a pressed state.
- Updated IntelliSense, which was missing information for many newer types and members.
- Fixed an issue where clicking in an empty area of a `ScrollViewer` would always move focus to the first focusable control in the `ScrollViewer` and scroll that control into view. For more info, see GitHub issue #597.
- Fixed an issue where the `Window.Activated` event sometimes fired multiple times. For more info, see GitHub issue #7343.
- Fixed an issue where setting the `NavigationViewItem.IsSelected` property to `true` prevented its children from showing when expanded. For more info, see GitHub issue #7930.
- Fixed an issue where `MediaPlayerElement` would not properly display captions with `None` or `DropShadow` edge effects. For more info, see GitHub issue #7981.
- Fixed an issue where the `Flyout.ShowMode` property was not used when showing the flyout. For more info, see GitHub issue #7987.
- Fixed an issue where `NumberBox` would sometimes have rounding errors. For more info, see GitHub issue #8780.
- Fixed an issue where using a library compiled against an older version of WinAppSDK could hit an error trying to find a type or property. For more info, see GitHub issue #8810.
- Fixed an issue where initial keyboard focus was not set when launching a window. For more info, see GitHub issue #8816.
- Fixed an issue where `FlyoutShowMode.TransientWithDismissOnPointerMoveAway` didn't work after the first time it was shown. For more info, see GitHub issue #8896.
- Fixed an issue where some controls did not correctly template bind `Foreground` and `Background` properties. For more info, see GitHub issue #7070, #9020, #9029, #9083 and #9102.
- Fixed an issue where `ThemeResource`s used in `VisualStateManager` setters wouldn't update on theme change. This commonly affected controls in flyouts. For more info, see GitHub issue #9198.
- Fixed an issue where `WebView` would lose key focus, resulting in extra blur/focus events and other issues. For more info, see GitHub issue #9288.
- Fixed an issue where `NavigationView` could show a binding error in debug output. For more info, see GitHub issue #9384.

- Fixed an issue where SVG files defining a negative viewbox no longer rendered. For more info, see GitHub issue #9415.
- Fixed an issue where changing `ItemsView.Layout` orientation caused an item to be removed. For more info, see GitHub issue #9422.
- Fixed an issue where scrolling a `ScrollView` generated a lot of debug output. For more info, see GitHub issue #9434.
- Fixed an issue where `MapContorl.InteractiveControlsVisible` did not work properly. For more info, see GitHub issue #9486.
- Fixed an issue where `MapControl.MapElementClick` event didn't properly fire. For more info, see GitHub issue #9487.
- Fixed an issue where x:Bind didn't check for null before using a weak reference, which could result in a crash. For more info, see GitHub issue #9551.
- Fixed an issue where changing the `TeachingTip.Target` property didn't correctly update its position. For more info, see GitHub issue #9553.
- Fixed an issue where dropdowns did not respond in WebView2. For more info, see GitHub issue #9566.
- Fixed a memory leak when using `GeometryGroup`. For more info, see GitHub issue #9578.
- Fixed an issue where scrolling through a very large number of items from an `ItemRepeater` in a `ScrollView` could cause blank render frames. For more info, see GitHub issue #9643.
- Fixed an issue where `SceneVisual` wasn't working.

New APIs in 1.6.0

Version 1.6.0 includes the following new APIs compared to the stable 1.5 release:

C#

```
Microsoft.UI

    ColorHelper
        ToDisplayName
```

C#

```
Microsoft.UI.Input

    EnteredMoveSizeEventArgs
    EnteringMoveSizeEventArgs
    ExitedMoveSizeEventArgs
    InputNonClientPointerSource
        EnteredMoveSize
```

```
        EnteringMoveSize
        ExitedMoveSize
        WindowRectChanged
        WindowRectChanging

    MoveSizeOperation
    WindowRectChangedEventArgs
    WindowRectChangingEventArgs
```

C#

```
Microsoft.UI.Xaml

    XamlRoot
        CoordinateConverter
```

C#

```
Microsoft.UI.Xaml.Automation.Peers

    ScrollPresenterAutomationPeer
```

C#

```
Microsoft.UI.Xaml.Controls

    PipsPager
        WrapMode
        WrapModeProperty

    PipsPagerWrapMode
    TabView
        CanTearOutTabs
        CanTearOutTabsProperty
        ExternalTornOutTabsDropped
        ExternalTornOutTabsDropping
        TabTearOutRequested
        TabTearOutWindowRequested

    TabViewExternalTornOutTabsDroppedEventArgs
    TabViewExternalTornOutTabsDroppingEventArgs
    TabViewTabTearOutRequestedEventArgs
    TabViewTabTearOutWindowRequestedEventArgs
```

C#

```
Microsoft.Windows.Globalization
```

```
    ApplicationLanguages
```

C#

```
Microsoft.Windows.Management.Deployment

    EnsureReadyOptions
        RegisterNewerIfAvailable

    PackageDeploymentFeature
    PackageDeploymentManager
        IsPackageDeploymentFeatureSupported
        IsPackageProvisioned
        IsPackageProvisionedByUri
        IsPackageReadyOrNewerAvailable
        IsPackageReadyOrNewerAvailableByUri
        IsPackageSetProvisioned
        IsPackageSetReadyOrNewerAvailable

    PackageReadyOrNewerAvailableStatus
```

C#

```
Microsoft.Windows.Storage

    ApplicationData
    ApplicationDataContainer
    ApplicationDataContract
    ApplicationDataCreateDisposition
    ApplicationDataLocality
```

Stable channel release notes for the Windows App SDK 1.5

Article • 09/05/2024

The stable channel provides releases of the Windows App SDK that are supported for use by apps in production environments. Apps that use the stable release of the Windows App SDK can also be published to the Microsoft Store.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 1.5.9 (1.5.250108004)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release.

- Fixed another potential issue where a menu off a CommandBar may incorrectly open up instead of down when the CommandBar is at the bottom of the window.
- Fixed a potential crash when running on older graphics hardware.

Version 1.5.8 (1.5.241107002)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release.

- Fixed a potential crash when the input queue on the thread appears to be in a bad state.
- Fixed some potential crashes when using `{x:Bind}` by checking every component for null. Apps wanting this fix need to recompile with this release.

Version 1.5.7 (1.5.241001000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release.

- Added detection for a rare scenario where the app stops rendering and never recovers.
- Fixed a potential crash when a UI thread uninitializes.
- Fixed a potential issue where a menu off a CommandBar might have incorrectly opened up instead of down when the CommandBar was at the bottom of the window.

Version 1.5.6 (1.5.240802000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release.

- Fixed an issue with `InputNonClientPointerSource` sometimes breaking input to the Min/Max/Close buttons. For more info, see GitHub issue #9749.
- Fixed a potential crash when closing a window while using a touchpad.

Version 1.5.5 (1.5.240627000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release.

- Fixed a potential crash during image loading when the image source is changed before loading completes.
- Fixed a potential crash when using `InputNonClientPointerSource`.
- Fixed an issue where a window containing only a WebView2 control doesn't correctly set initial keyboard focus into the WebView2, leaving it unusable by keyboard and accessibility tools. For more info, see GitHub issue WebView2Feedback#2330.

Version 1.5.4 (1.5.240607001)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release.

- Fixed an issue with the fix for GitHub issue #8857 to properly merge a library's resources.pri into the app's resources.pri.
- Fixed an issue where WebView2 sent extra `blur` and `focus` events on every click. For more info, see GitHub issue #9288. This also fixes problems with dropdowns not responding, as seen in GitHub issue #9566.
- Fixed an issue where creating a new window or popup canceled any in-progress drag operation. For more info, see GitHub issue #9360.
- Fixed an issue where SVG files defining a negative viewbox no longer rendered. For more info, see GitHub issue #9415.
- Fixed an issue where `x:Bind` didn't check for **null** before using a weak reference, which could result in a crash. For more info, see GitHub issue #9551.
- Fixed an issue where a resize cursor was incorrectly shown at titlebar edges when a window was maximized, which also caused incorrect behavior when clicking or dragging in those areas. For more info, see GitHub issue #8665.

Version 1.5.3 (1.5.240428000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release.

- Fixed an issue where `ItemsRepeater` sometimes caused its window to be brought to the front.
- Fixed a potential crash when the transparency state of an `AcrylicBrush` was updated.
- Fixed an issue where `ItemsRepeater` would not generate enough items if it was in a `ShouldConstrainToRootBounds="false"` popup that was taller or wider than the main window.
- Fixed an issue where error **MSB4086** could occur at build time if the project file didn't specify a *TargetPlatformVersion*. This error was hit as part of GitHub issue #9531.

Version 1.5.2 (1.5.240404000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release and a new feature for Widget feed providers.

Widget feed provider updates

- Feed providers are now able to show announcements in the Widgets Dashboard:
  - The new `FeedManager.TryShowAnnouncement` API allows a Feed Provider to request that the Widget Dashboard show their announcements. To show your announcement, create a `FeedAnnouncement` object and call the `FeedManager.TryShowAnnouncement` API.
  - Feed announcements will have their own badges displayed in the taskbar that can be customized using the `FeedAnnouncement` API.
- Feed providers can now opt in to receive Analytics and Error Reports information about their provider as a user interacts with it. To opt in, implement the `IFeedProviderAnalytics` and/or `IFeedProviderErrors` interfaces by your provider.

The feed provider updates includes the following new APIs:

C#

```
Microsoft.Windows.Widgets.Feeds.Providers

    FeedAnalyticsInfoReportedArgs
    FeedErrorInfoReportedArgs
    FeedManager
        SendMessageToContent
        TryShowAnnouncement

    FeedMessageReceivedArgs
    FeedResourceRequest
    FeedResourceRequestedArgs
    FeedResourceResponse
    IFeedAnnouncementInvokedTarget
    IFeedManager2
    IFeedProviderAnalytics
    IFeedProviderErrors
    IFeedProviderMessage
    IFeedResourceProvider
```

C#

```
Microsoft.Windows.Widgets.Notifications

    AnnouncementActionKind
    AnnouncementTextColor
    FeedAnnouncement
    FeedAnnouncementInvokedArgs
```

Bug fixes

- Fixed an issue where `DispatcherTimer` would not fire at the correct time if the primary display wasn't running at 60 Hz.
- Fixed an issue where a textbox input method editor (IME) window would be incorrectly positioned when running at a scale factor other than 100%. For more info, see GitHub issue #9382.
- Fixed an issue where a drag-and-drop operation started from another app might not allow the correct Copy/Move/Link drop operations.
- Fixed a potential crash when a ListView's `ItemsSource` is reset and given focus right away.
- Fixed a problem where `ShouldConstrainToRootBounds="false"` popups/flyouts don't apply any inherited scale transform. For more info, see GitHub issues #9118 and #9433.
- Fixed a potential crash when a Composition object is destroyed with an animation still running.
- Fixed a potential crash on shutdown in `NavigationView::RevokeNavigationViewItemRevokers`.

Version 1.5.1 (1.5.240311000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.5 release.

- Fixed an issue where self-contained apps may fail to build due to not being able to copy "map.html".
- Fixed an issue where `MapControl` would fail to initialize due to rejecting valid tokens. For more info, see GitHub issue #9324.
- Fixed an issue where `MapControl` loaded with a blue background. For more info, see GitHub issue #9377.
- Fixed an issue where clicking on the chevron of a `NavigationViewItem` did not correctly expand or collapse on a single click. This also caused menus to show as blank when clicking the chevron in `PaneDisplayMode="Top"` mode. For more info, see GitHub issues #9423 and #9426.
- Fixed an issue where tapping on a `NavigationViewItem` with touch or pen would prevent the item from responding to any future input. For more info, see GitHub issue #9429.
- Fixed a crash when clicking on an item in the `NavigationView.PaneFooter` area. For more info, see GitHub issue #9396.
- Fixed an issue where icons in menus were sometimes showing in the wrong place. For more info, see GitHub issue #9409.

- Fixed an issue where acrylic does not show on menus until switching away from the window and back. For more info, see GitHub issue #9406.
- Fixed a crash which could occur during `TextBox`/`RichEditBox` initialization. For more info, see GitHub issue #9216.
- Fixed some noisy exceptions which `NavigationView` threw and caught on destruction.
- Fixed an issue where a "pinch to zoom" gesture would sometimes show up as a pan or tap due to an incorrect `PointerCaptureLost` message firing.

Version 1.5

The following sections describe new and updated features and known issues for version 1.5.

In an existing Windows App SDK 1.4 app, you can update your Nuget package to 1.5.240227000 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Downloads for the Windows App SDK.

XAML Islands runtime and shutdown updates

There is a behavioral difference between WinAppSDK 1.4 and WinAppSDK 1.5 for XAML Islands-based apps when the last XAML Window on any thread is closed.

- In WinAppSDK 1.4, the XAML runtime always exits the thread's event loop when the last XAML window on a thread is closed.
- In WinAppSDK 1.5:
  - If your app is a WinUI Desktop app, the default behavior is still the same as in WinAppSDK 1.4.
  - If you're using XAML for the DesktopWindowXamlSource ("XAML Islands") API, the default behavior is now that XAML does not automatically exit the thread's event loop.
  - In both modes, you can change this behavior by setting the `Application.DispatcherShutdownMode` property.

For more information, see the documentation for the `Application.DispatcherShutdownMode` property when available. This completes GitHub proposal #8492.

There is a behavioral difference between WinAppSDK 1.4 and WinAppSDK 1.5 for XAML Islands-based apps in the lifetime of the XAML runtime:

- In WinAppSDK 1.4, the XAML runtime shuts down on a thread if either all `WindowsXamlManager` and `DesktopWindowXamlSource` objects on a given thread are closed or shut down, or the `DispatcherQueue` running on that thread is shut down (in this case, the XAML runtime shuts down during the `DispatcherQueue.FrameworkShutdownStarting` stage).
- In WinAppSDK 1.5, the XAML runtime shuts down on a thread only when the DispatcherQueue running on that thread is shut down (the Xaml runtime always shuts down during the `DispatcherQueue.FrameworkShutdownStarting` stage).

For more information, see the documentation for the `WindowsXamlManager` class when available.

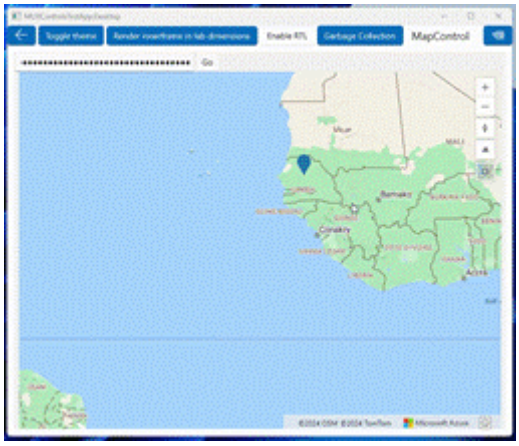
There is a behavioral difference in `WindowsXamlManager.InitializeForCurrentThread()`:

- In WinAppSDK 1.4, `WindowsXamlManager.InitializeForCurrentThread()` returns a unique instance of a `WindowsXamlManager` object with each call.
- In WinAppSDK 1.5, `WindowsXamlManager.InitializeForCurrentThread()` returns an existing instance if one already exists on the thread. `Close/Dispose()` is now ignored.

WinUI Maps control

The WinUI `Maps` control is now available! This control is powered by WebView2 and Azure Maps, providing the following features:

- Panning and zooming with either the map buttons or touch.
- Changing the style of the map to satellite, terrain, or street view.
- Programmatically adding interactable pins with developer-customizable icons to the map.
- Developer customization for where the map is centered on initial load.
- Control for developers over hiding or showing the buttons for panning, zooming, and map styles.

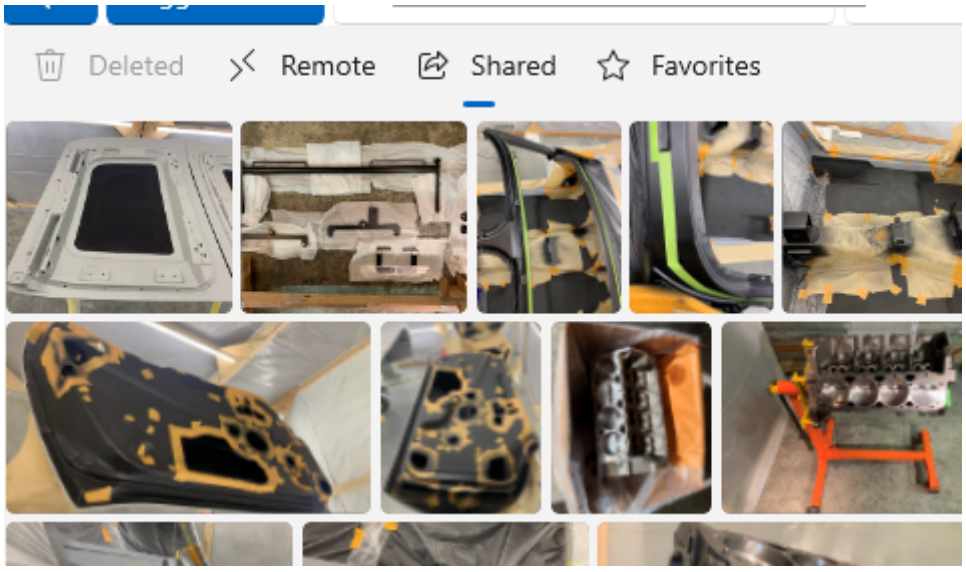


> **Note**
>
> To use the `Maps` control, you'll need an Azure Maps key. To create the key, see the Azure Maps documentation page for creating a web app.

The `Maps` control is entirely new and we welcome your feedback to evaluate its future direction!

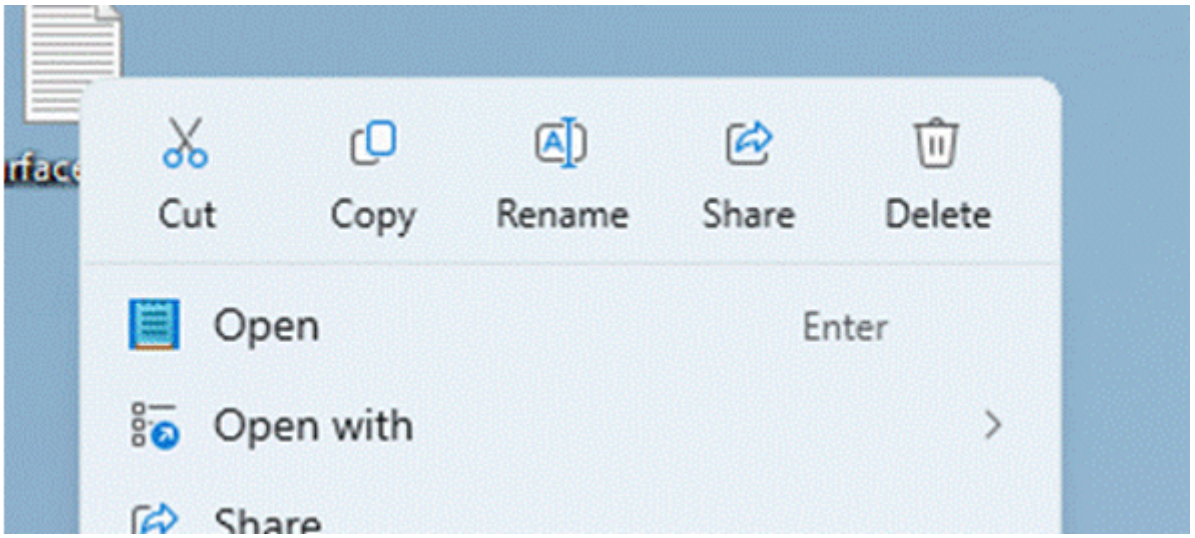
New SelectorBar control

In 1.5, we've added a new `SelectorBar` control for enabling users to switch between multiple views of data. This control was previously known as "SegmentedControl" on our 1.5 roadmap.



Labels in the CommandBarFlyout primary commands

The visuals of the `CommandBarFlyout` have been updated to display a text label for the items in the primary commands area if the `Label` property has been set on the `AppBarButton`. Previously, the primary commands in the `CommandBarFlyout` area only displayed an icon, but now they can show both an icon and a label for improved usability.



WebView2 support for custom environment/options

The WinUI `WebView2` control now exposes the ability to customize the underlying `CoreWebView2` object with a custom `CoreWebView2Environment` and `CoreWebView2ControllerOptions`. This enables the app author to specify an alternate path from which to load the WebView2Runtime, choose to use a different *UserDataFolder*, or set options such as *IsPrivateModeEnabled* and *ScriptLocale*.

Support for .NET 8

We added support for .NET 8 in a recent 1.4 servicing release, but that still kept the warning for the use of platform-specific RIDs. In 1.5, we completed that work so that the warning is no longer present.

Improved debugging and source availability

We now inject Github source server information for code in the microsoft-ui-xaml repo into our public symbols, allowing debuggers to automatically download source code. We also made other fixes and improvements to our symbols across the entire WinAppSDK to improve the debugging experience.

Improved functionality for debugging layout cycles

Debugging layout cycles in a WinUI app can be a challenge, so in 1.5 the `DebugSettings` object now exposes options to enable improved logging and breakpoints for the layout process to make it easier to debug and fix layout cycles in the app.

Other new features from across the WinAppSDK

- Added support for the PublishSingleFile deployment model. For more info about PublishSingleFile, see the Single-file deployment documentation.
- Added improvements to screen reader support, text scaling support, and other accessibility features.
- Various stability and performance improvements based on our prioritized GitHub bug backlog.

New features being released separately

New versions of the WinAppSDK Visual Studio Templates for C# and C++ are being released through the Visual Studio Marketplace and they will appear a few weeks after the release of 1.5. With the new version, the templates may now be released independently of WinAppSDK releases, giving us much more flexibility in getting updates to customers.

Other previously planned features

In 1.5, we made progress on the following features that we announced on our roadmap, but did not complete them. They will continue into the 1.6 timeframe.

- Tabbed windows
- Drag-n-drop support for WebView2
  - To clarify, in 1.5 dragging *into* WebView2 is supported, such as dragging a PNG from File Explorer into Bing for Visual Search. Work is ongoing in 1.6 to support dragging *out* of WebView2.
- Investigations into the table view and ink controls

Dynamic lighting has been removed from the roadmap for the time being.

Known issues

- When using libraries which contain resources such as .xaml files, you may hit an error message at runtime indicating that those resources cannot be found. In this case, it might be necessary to insert `<ShouldComputeInputPris>true</ShouldComputeInputPris>` in the project file to ensure those resources get included.
- Clicking on the chevron of a `NavigationViewItem` no longer correctly expands or collapses on a single click. Double-clicking still works, as does clicking elsewhere on the `NavigationViewItem`.

Bug fixes

- Fixed an issue where `StackPanel` applied spacing to collapsed items. For more info, see GitHub issue #916.
- Fixed problems with scrolling controls no longer working after closing another app window. Fore more info, see GitHub issues #9292 and #9355.
- Fixed a crash when setting `DebugSettings.EnableFrameRateCounter` to *true* before the first frame rendered. For more info, see GitHub issue #2835.
- Fixed a potential compile error for C++ where some headers did not include necessary dependencies. Note that the change of `#include` order might impact some apps, such as possibly causing a compile error for `IInspectable` if the app is using a version of C++/WinRT older than 2023. For more info, see GitHub issue #9014.
- Fixed an issue where `ElementName` bindings didn't work inside the `ItemsRepeater` `DataTemplate`. For more info, see GitHub issue #560.
- Fixed crashes when running an app under Visual Studio with the in-app toolbar enabled. Visual Studio 17.8 Preview 2 or later is required to fully get the fixes. For more info, see GitHub issue #8806.
- Fixed an issue where `AnnotatedScrollbar` could sometimes crash when quickly scrolling.
- Fixed an issue where menu text would sometimes get truncated.
- Fixed an issue where teaching tips did not receive proper focus. For more info, see GitHub issue #3257.
- Fixed an issue that crashed the application when setting the `TailVisibility` of a `TeachingTip` to *Collapsed* on startup. For more info, see GitHub issue #8731.
- Fixed an issue with how PRI files were handled when using libraries. For more info, see GitHub issue #8857.
- Fixed an issue from the 1.5-experimental2 release where the projection DLL was not generated. For more info, see GitHub issue #4152.
- Fixed an issue where the ellipsis button on the text formatting popup of the `RichEditBox` was not displaying the list of actions properly. For more info, see GitHub issue #9140.
- Fixed an issue where `ListView` didn't handle keyboard accelerators properly. For more info, see GitHub issue #8063.
- Fixed an access violation issue with using `AccessKey` to close a window. For more info, see GitHub issue #8648.
- Fixed a crash when using an `AccessKey` to close a window. For more info, see GitHub issue #9002.
- Fixed an issue affecting text alignment in a `MenuFlyoutItem` within a `MenuBar`. For more info, see GitHub issue #8755.

- Fixed an issue where highlighted text would not remain highlighted upon right-click. For more info, see GitHub issue #1801.
- Fixed an issue causing inactive windows to crash the app when closed. For more info, see GitHub issue #8913.
- Fixed an issue that could hang applications when scrolling with the middle mouse button and left-clicking immediately afterwards. For more info, see GitHub issue #9233.
- Fixed an issue causing apps to crash on startup when using a custom `NavigationViewItem`. For more info, see GitHub issue #8814.
- Fixed a `NavigationView` issue where the ellipsis button would incorrectly generate an error. For more info, see GitHub issue #8380.
- Fixed an issue where a `SystemBackdrop` would not render properly in a multi-window app. For more info, see GitHub issue #8423.
- Fixed a duplication issue when inserting into the beginning of an `ObservableCollection`. For more info, see GitHub issue #8370.

Stable channel release notes for the Windows App SDK 1.4

Article • 05/23/2024

The stable channel provides releases of the Windows App SDK that are supported for use by apps in production environments. Apps that use the stable release of the Windows App SDK can also be published to the Microsoft Store.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 1.4.7 (1.4.240802001)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.4 release.

- Fixed an issue where `ItemsRepeater` would not generate enough items if it was in a `ShouldConstrainToRootBounds="false"` popup which was taller or wider than the main window.
- Fixed a potential crash on shutdown if an `AnnotatedScrollBar` label update was pending.

Version 1.4.6 (1.4.240512000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.4 release.

- Fixed a potential crash when processing input.
- Fixed an issue where a drag-and-drop operation that started from another app might not allow the correct Copy/Move/Link drop operations.
- Fixed WinUI source server information for debugging to properly point to the microsoft-ui-xaml GitHub repo.
- Fixed an issue with the fix for GitHub issue #8857 to properly merge a library's `resources.pri` into the app's `resources.pri`.

Version 1.4.5 (1.4.240211001)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.4 release.

- Fixed an issue that could hang applications when clicking a mouse button while scrolling with the mouse wheel. For more info, see GitHub issue #9233.
- Fixed an issue with duplicate assets when referencing a chain of NuGet packages. For more info, see GitHub issue #8857.
- Fixed several `BreadcrumbBar` issues including a memory leak, a crash when the ellipsis menu is empty, and the ellipsis menu being incorrectly constrained within the window.
- Fixed a potential crash on shutdown when releasing graphics resources.

Version 1.4.4 (1.4.231219000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.4 release.

- Fixed a WinUI 3 diagnostics security issue.
- Fixed an input issue where the password box didn't show the on-screen keyboard when activated via touch. For more info, see GitHub issue #8946.
- Fixed an issue that caused the `Microsoft.UI.Xaml.Controls.dll` file size to grow unexpectedly.
- Fixed a `CommandBarFlyout` issue that could cause crashes when setting focus.
- Updated Windows App SDK support for .NET 8 RID-specific asset handling.
- Fixed an issue causing some swapchains to be positioned or stretched incorrectly.

Version 1.4.3 (1.4.231115000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.4 release.

- Fixed an issue where a menu could appear without a background for a short period of time.
- Fixed a crash that may occur in specific multi-monitor scenarios.
- Fixed an issue where a context menu could appear off-screen.
- Fixed an issue with Window styles and maximizing behavior. For more info, see GitHub issue #8996.
- Fixed an issue with Islands where focus could be unexpectedly grabbed from another control.
- Fixed an issue with tab order on `NavigationView`.
- Fixed a rendering issue where a white bar might be visible at the top of the titlebar. For more info, see GitHub issue #8947.
- Various performance fixes.

Version 1.4.2 (1.4.231008000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.4 release.

- Fixed a crashing issue in explorer.exe caused by excessive memory and object allocation.
- Fixed a titlebar interaction issue that prevented the back button from working properly.
- Fixed an issue that caused a warning to be generated for a source file being included multiple times.
- Fixed an issue impacting context menu performance.
- Fixed a .lnk shortcut issue that made the target .exe always point to the same location for packages in the WindowsApps folder.
- Fixed a DWriteCore issue affecting proper rendering of Indic text in certain fonts.
- Fixed an issue in a List View that prevented proper keyboard navigation to and from nested selected items with *Tab/Shift + Tab*.
- Fixed an issue that broke scrolling ComboBox items by touch after expanding the ComboBox a second time. For more info, see GitHub issue #8831.
- Fixed an issue where WinAppSDK packages did not include WinUI's localized resources for some languages.
- Fixed an inconsistency between how File Explorer and XAML display a user's preferred language.
- Fixed a craftsmanship issue in File Explorer causing a thin line to show under the active tab.

- Fixed an issue where some framework-provided keyboard accelerators were not properly localized. For more info, see GitHub issue #2023.
- Fixed an issue with RepeatButton controls that were repeatedly scrolling when tapped.
- Fixed the WinAppSDK installer .exe to have proper resource version info.

Version 1.4.1 (1.4.230913002)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.4 release.

- Fixed performance issues to improve the time to first frame.
- Fixed an issue where menus didn't respect `RequestedTheme`. For example, it was possible for this issue to lead to white text on a white background. For more info, see GitHub issue #8756.
- Fixed an issue that caused acrylic backgrounds to sometimes become fully transparent in some menus.
- Fixed an issue where XAML sometimes caused Windows to unnecessarily repaint the desktop wallpaper.
- Fixed support for `TabNavigation = Local` and `TabNavigation = Cycle` for `ListView` and `GridView`, which now enables navigating between headers and items with TAB in addition to arrow keys.
- Fixed some noisy exceptions when dismissing a tooltip. For more info, see GitHub issue #8699.

New and updated features and known issues for version 1.4

The following sections describe new and updated features and known issues for version 1.4.

In an existing Windows App SDK 1.3 app, you can update your Nuget package to 1.4.230822000 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Latest Windows App SDK downloads.

Custom titlebar + AppWindow titlebar merger

The WinUI 3 custom titlebar uses the AppWindow titlebar implementation, along with the NonClientInputPointerSource APIs, under the hood in the Windows App SDK 1.4. As

a result, both titlebar implementations now behave the same way with the same features and limitations. This is fully backwards compatible in all supported cases - any app with a custom-defined titlebar will behave as before. But, it's now easier for WinUI 3 developers who might be new to custom titlebars to understand and use them by taking advantage of these new features:

- A better default scenario where the developer doesn't define a titlebar element specifically (replacing the fallback titlebar from WinUI 2)
- Distinct drag regions in the titlebar, enabling you to create multiple drag regions and place clickable controls on any part of the non-client area (titlebar area)
- App-wide draggable regions that can be put anywhere in the app or make the whole app draggable
- Better theming support that replaces resource-based theming
  - Since drag regions are transparent, they follow the app theme every time
- More customization: hide the min, max, and close buttons; place system icons in the titlebar; or have different regions act as caption buttons that receive NCHITTEST responses
- More developer freedom that enables you to mix and match with AppWindow titlebar APIs, such as using higher-level WinUI 3 APIs for most scenarios but with AppWindow APIs mixed in for lower-level control

Widgets updates

Three new interfaces have been added for Widget Providers to implement: `IWidgetProvider2`, `IWidgetProviderAnalytics`, and `IWidgetProviderErrors`. `IWidgetProvider2` allows providers to respond to the *Customize* action invoked by the user, which is identical to what is available for 1st party Widgets. The `IWidgetProviderAnalytics` and `IWidgetProviderErrors` interfaces are used by providers to gather telemetry for their widgets; analytics and failure events about widgets are communicated to the respective widget providers. The `WidgetCustomizationRequestedArgs`, `WidgetAnalyticsInfoReportedArgs`, and `WidgetErrorInfoReportedArgs` classes are used to communicate relevant information to support new functionalities.

XAML Islands no longer experimental

XAML Islands and the underlying ContentIslands platform are no longer experimental.

- Currently XAML Islands are only tested for use in C++ apps. This release does not include any convenient wrapper elements for use in WPF or WinForms.

- `DesktopWindowXamlSource` and related types have been added in the Microsoft.UI.Xaml.Hosting namespace for XAML Islands. `XamlRoot.ContentIslandEnvironment` was added to help access the underlying Island information for an element.
- Many new types have been introduced in the Microsoft.UI.Content namespace and the Microsoft.UI.Input namespace as the underlying support for XAML Islands or for using this ContentIslands functionality without XAML.
- A new `DragDropManager` (plus related types) has been added in the Microsoft.UI.Input.DragDrop namespace for Island scenarios.

ItemsView

We're introducing a new list control called the `ItemsView` and a corresponding concrete `ItemContainer` class. `ItemContainer` is a lightweight container with built-in selection states and visuals, which can easily wrap desired content and be used with `ItemsView` for a collection control scenario.

- The new `ItemsView` control displays a data collection. `ItemsView` is similar to the `ListView` and `GridView` controls, but is built using the `ItemsRepeater`, `ScrollView`, `ItemContainer` and `ItemCollectionTransitionProvider` components. It offers the unique ability to plug in custom `Layout` or `ItemCollectionTransitionProvider` implementations. Another key advantage is the ability to switch the layout on the fly while preserving items selection. The inner `ScrollView` control also offers features unavailable in `ListView`/`GridView`'s `ScrollViewer` control such as the ability to control the animation during programmatic scrolls.
  - A new `ItemTransitionProvider` property on `ItemsRepeater` (and the new `ItemsView` control) lets you specify an `ItemCollectionTransitionProvider` object to control transition animations on that control. A `CreateDefaultItemTransitionProvider` method has also been added to `Layout`, which enables a layout object to provide a fallback transition to accompany it if you do not provide one explicitly on the `ItemsView` control.
  - A new `IndexBasedLayoutOrientation` property on `Layout` where the layout orientation, if any, of items is based on their index in the source collection. The default value is `IndexBasedLayoutOrientation.None`. Custom layouts set this property by calling the new (protected) `SetIndexBasedLayoutOrientation` method.
  - A new `VisibleRect` property on `VirtualizingLayoutContext` gets the visible viewport rectangle within the `FrameworkElement` associated with the `Layout`. The protected virtual `VirtualizingLayoutContext.VisibleRectCore` method can be

overridden to provide the value that will be returned from the `VisibleRect` property.

- The new `LinedFlowLayout` class is typically used to lay out the items of the `ItemsView` collection control. It is particularly useful for displaying collection of pictures. It does so by laying them out from left to right, and top to bottom, in lines of equal height. The pictures fill a horizontal line and then wrap to a next line. Pictures may be cropped at the left and right edges to fit into a line. They may also be expanded horizontally and cropped at the top and bottom edges to fill a line when the stretching mode is employed.

New features from across the WinAppSDK

- A new `ThemeSettings` class that allows Win32 WinRT apps to detect when the system's High Contrast setting has changed, similar to UWP's AccessibilitySettings class. See the ThemeSettings API spec on GitHub for more information.
- `AccessKeyManager.EnterDisplayMode` is a new method to display access keys for the current focused element of a provided root. Access keys are in "display mode" when showing a key tip to invoke a command, such as pressing the Alt key in Paint to show what keys correspond to what controls. This method allows for programmatically entering display mode.
- `Application.ResourceManagerRequested` provides a mechanism to provide a different `IResourceManager` to resolve resource URIs for scenarios when the default `ResourceManager` won't work. For more information, see the Application.ResourceManagerRequested API spec on GitHub.
- The version of the WebView2 SDK was updated from 1661.34 to 1823.32.
- `Popup/FlyoutBase.IsConstrainedToRootBounds = false` is now supported, allowing a popup/flyout to extend outside the bounds of the parent window. A `SystemBackdrop` property has been added to these types to support having acrylic in these unconstrained popups. Menus by default use this to have acrylic.
- `Closed`, `FrameworkClosed`, and `IsClosed` have been added to `DesktopAcrylicController` and `MicaController` to improve handling during object/thread shutdown.
- `DesktopAcrylicController.Kind` can now be set to choose between some standard acrylic appearances.
- `DispatcherQueue` has some new events and helpers to facilitate better organized shutdown and for apps using Islands to easily run a standard supported event loop.
- `InputNonClientPointerSource` in the Microsoft.UI.Input namespace can be used for custom titlebar scenarios to define non-client area regions. Code can register for

corresponding events like hover and click events on these regions.

- `AppWindow` has some new helpers to get and associate with a `DispatcherQueue`.
- The new `TreeView.SelectionChanged` event allows developers to respond when the user or code-behind changes the set of selected nodes in the `TreeView` control.
- The new `ScrollView` control provides a new alternative to `ScrollViewer`. This new control is highly aligned in behavior and API with the existing `ScrollViewer` control, but is based on `InteractionTracker`, has new features such as animation-driven view changes, and is also designed to ensure full functionality of `ItemsRepeater`. See A more flexible ScrollViewer · Issue #108 · microsoft/microsoft-ui-xaml (github.com) for more details. Various new types, including `ScrollPresenter`, are part of the overall `ScrollView` model.
- The new `AnnotatedScrollBar` control extends a regular scrollbar's functionality by providing an easy way to navigate through a large collection of items. This is achieved through a clickable rail with labels that act as markers. It also allows for a more granular understanding of the scrollable content by displaying a tooltip when hovering over the clickable rail.

Known issues

- When using `ExtendsContentIntoTitleBar = true`, clicks at the top-left corner of the window by default always show the system window menu (Minimize/Close/etc.) rather than letting the pointer input through to the content of the window. This, for example, means that a Back button in that area of the titlebar will not work. A workaround for this issue is to set `AppWindow.TitleBar.IconShowOptions = Microsoft.UI.Windowing.IconShowOptions.HideIconAndSystemMenu` on the Window's AppWindow.
- There are some new continuable exceptions when hiding `ShouldConstrainToRootBounds="False"` popups/flyouts. That includes hiding tooltips, as reported here: Dismissing a tooltip throws 4 native exceptions · Issue #8699 · microsoft/microsoft-ui-xaml (github.com)
- In 1.4, the min/max/close caption buttons for `ExtendsContentIntoTitleBar = true` are now drawn by AppWindow rather than XAML. This is by design, but it can impact apps that were overriding XAML's internal styles to hide or do extra customization of these buttons, such as in this report: Cannot hide caption button on titlebar · Issue #8705 · microsoft/microsoft-ui-xaml (github.com)
- There was a breaking change in .NET 8 to how it handles the runtime identifier graph: [Breaking change]: Projects targeting .NET 8 and higher will by default use a smaller, portable RID graph. · Issue #36527 · dotnet/docs (github.com). Because of this issue and because .NET 8 has not officially released yet, the Windows App

SDK 1.4 does not officially support .NET 8. However, if you would still like to target the pre-release version of .NET 8 with this version of the App SDK, we recommend the following steps:

  - Setting UseRidGraph to true is recommended. You'll also need to update the `<RuntimeIdentifiers>` property in the `.csproj` file to `<RuntimeIdentifiers>win-x86;win-x64;win-arm64</RuntimeIdentifiers>`, as well as update each `Propeties\*pubxml` file to switch from `win10` to `win` in the `<RuntimeIdentifier>` property (for example, `<RuntimeIdentifier>win-x86</RuntimeIdentifier>`).

- With Windows App SDK 1.4, the target `GenerateDeploymentManagerCS` in `Microsoft.WindowsAppSDK.DeploymentManager.CS.targets` was renamed to `GenerateBootstrapCS`.
- `MenuFlyout` background doesn't use the application's requested theme:
  - MenuFlyoutItem text doesn't sync with system theme. · Issue #8678 · microsoft/microsoft-ui-xaml (github.com)
  - 1.4 preview: Flyout backdrop theme is derived from system theme and not from its associated element · Issue #8756 · microsoft/microsoft-ui-xaml (github.com)

Bug fixes

- Fixed an issue where calling the `Microsoft.Windows.AppLifecycle.AppInstance.Restart("")` API caused unpackaged apps to crash. For more info, see GitHub issue #2792.
- Fixed an installer crashing issue that was introduced in 1.4-experimental1. For more info, see GitHub issue #3760.
- Fixed an issue where text strikethrough was not removed properly in a TextBlock. For more info, see GitHub issue #1093.
- Fixed an issue causing incorrect Shift + Tab navigation in a Panel with *TabFocusNavigation* set to "Once." For more info, see GitHub issue #1363.
- Fixed an issue in C++/WinRT that prevented `{x:Bind}` from working properly with a property of a named XAML control. For more info, see GitHub issue #2721.
- Fixed a runtime AccessViolation issue in WinUI Desktop apps caused by setting `DebugSettings.EnableFrameRateCounter = true`. For more info, see GitHub issue #2835.
- Fixed an issue where `XamlTypeInfo.g.cpp` did not include needed headers. For more info, see GitHub issue #4907.
- Fixed a crashing issue caused by simultaneous multi-touch and mouse input. For more info, see GitHub issue #7622.
- Fixed an issue that prevented an active WinUI 3 app window from scrolling when the system setting to disable scrolling of inactive windows on mouse over was in effect. For more info, see GitHub issue #8764.

- Fixed a crash when trying to subclass `MediaPlayerElement`.
- Fixed some crash and memory leak issues in `TreeView`.
- Fixed an app hang issue that could happen when using keyboard to navigate in `RadioButtons`.
- Fixed a crash when using the keyboard to navigate in a `PipsPager`.
- Fixed WebView2 content to scale with the "Text size" Accessibility setting in the Settings app.
- Fixed a crash that could occur when animations were running when the display turned off.
- Fixed a performance issue introduced in 1.3 that added a ~10% overhead to first layout/render.

Stable channel release notes for the Windows App SDK 1.3

Article • 05/23/2024

The stable channel provides releases of the Windows App SDK that are supported for use by apps in production environments. Apps that use the stable release of the Windows App SDK can also be published to the Microsoft Store.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 1.3.3 (1.3.230724000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.3 release.

- Fixed an issue where the mouse would sometimes stop working when a dialog box was closed.
- Fixed a deployment issue that prevented apps from installing due to a mismatch of package versions on the system. For more information, see GitHub issue #3740.
- Fixed an issue affecting context menu positioning in Windows App SDK 1.3.
- Fixed an issue causing some WinUI3 apps, in some situations, to crash when the app was closed because XAML shut itself down too early.

- Fixed an issue where font icons were not mirroring properly in right-to-left languages. For more information, see GitHub issue #7661.
- Fixed an issue causing an app to crash on shutdown when resources were torn down in a bad order. For more information, see GitHub issue #7924.

Version 1.3.2 (1.3.230602002)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.3 release.

- Fixed a crash when setting a Protected Cursor.
- Fixed a performance issue in XamlMetadataProvider during app startup. For more information, see GitHub issue #8281.
- Fixed an issue with hyperlinks and touch in a RichTextBlock. For more information, see GitHub issue #6513.
- Fixed an issue with scrolling and touchpads in WebView2. For more information, see GitHub issue #7772.
- Fixed an issue where an update of Windows App SDK sometimes required a restart of Visual Studio. For more information, see GitHub issue #3554.
- Fixed a noisy exception on shutdown when running in a debugger.

Version 1.3.1 (1.3.230502000)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.3 release.

- Fixed issue causing apps to crash when setting the SystemBackdrop if the Content was null. For more information, see GitHub issue #8416.
- Fixed issue causing apps to crash when setting the Window Title in XAML, a new capability added in 1.3.0. For more information, see GitHub issue #3689.
- Fixed issue where a window incorrectly took focus when its content changed.
- Fixed an issue with creating C++ projects with the WinAppSDK 1.3 project templates.
- Updated templates on Visual Studio Marketplace

New and updated features and known issues for version 1.3

The following sections describe new and updated features and known issues for version 1.3.

In an existing Windows App SDK 1.2 app, you can update your Nuget package to 1.3.230331000 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Latest Windows App SDK downloads.

XAML Backdrop APIs

With properties built in to the XAML Window, Mica & Background Acrylic backdrops are now easier to use in your WinUI 3 app. See the System Backdrop and Mica Backdrop API docs for more information about the Xaml Backdrop properties.

```
C#

public MainWindow()
{
    this.InitializeComponent();

    this.SystemBackdrop = new MicaBackdrop();
}
```

Window.AppWindow

By replacing several lines of boilerplate code, you're now able to use AppWindow APIs directly from a **Window** through Window.AppWindow.

New features from across WinAppSDK

- `ApplicationModel.DynamicDependency`: `PackageDependency.PackageGraphRevisionId` that replaces the deprecated MddGetGenerationId.
- Environment Manager: EnvironmentManager.AreChangesTracked to inform you whether changes to the environment manager are able to be tracked in your application.
- A new event, DebugSettings.XamlResourceReferenceFailed is now raised when a referenced Static/ThemeResource lookup can't be resolved. This event gives access to a trace that details where the framework searched for that key in order to better enable you to debug Static & ThemeResource lookup failures. For more information, see the Tracing XAML resource reference lookup failures API spec on GitHub.

Other updates

- See our WinAppSDK 1.3 milestone on the WinAppSDK GitHub for additional issues addressed in this release.
- See our WinUI 3 in WinAppSDK 1.3 milestone on the microsoft-ui-xaml GitHub for additional issues addressed in this release.
- With the latest experimental VSIX, you're now able to convert your app between unpackaged and packaged through the Visual Studio menu instead of in your project file.

Known issue

Due to a recent change to the xaml compiler, an existing project that upgrades to 1.3 may experience a build error like the following within Visual Studio:

Console

```
>
C:\Users\user\\.nuget\packages\microsoft.windowsappsdk\\**1.3.230331000**\bu
ildTransitive\Microsoft.UI.Xaml.Markup.Compiler.interop.targets(537,17):
error MSB4064: The "PrecompiledHeaderFile" parameter is not supported by the
"CompileXaml" task loaded from assembly: Microsoft.UI.Xaml.Markup.Compiler,
Version=1.0.0.0, Culture=neutral, PublicKeyToken=de31ebe4ad15742b from the
path:
C:\Users\user\\.nuget\packages\microsoft.windowsappsdk\\**1.2.230118.102**\t
ools\net472\Microsoft.UI.Xaml.Markup.Compiler.dll. Verify that the parameter
exists on the task, the <UsingTask> points to the correct assembly, and it
is a settable public instance property.
```

This is caused by Visual Studio using a cached xaml compiler task dll from 1.2, but driving it with incompatible MSBuild logic from 1.3, as seen in the error text above. The workaround is to shut down Visual Studio, restart it, and reload the solution.

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 1.2.5 (1.2.230313.1)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.2 release.

- Fixed issue causing apps to crash during Composition shutdown.
- Fixed issue causing apps to continue running animations even when the screen is off.
- Fixed issue causing mouse and touch input to fail in WebView2 when mouse and keyboard input occurred simultaneously. For more information, see GitHub issue #3266.

Version 1.2.4 (1.2.230217.4)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.2 release.

- Fixed issue causing self-contained apps to not be able to set UAC Settings. For more information, see GitHub issue #3376.
- Fixed issue causing push notifications to return an inaccurate Expiration time with `PushNotificationChannel::ExpirationTime`. For more information, see GitHub issue #3300.
- Fixed issue causing negative numbers to be considered "invalid" when passing a double as a parameter into an x:Bind function.
- Several fixes to update the WinUI VSIX. These updates included simplifying the project template dipAwareness in app.manifest, removing the UWP templates, updating localized resource files, adding the phone id to unblock store submission, and removing the copyright notice and license. For more info see GitHub issues #5659, #3205, #3323, #3322, #3143.

Version 1.2.3 (1.2.230118.102)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.2 release.

- Fixed issue causing WinUI 3 apps to crash when multiple windows are closed.
- Fixed issue causing a crash on app close when two or more references to the ThreadPoolTimer interface are called. For more information, see GitHub issues #7260 and #7239.
- Fixed issue causing all Single-project MSIX apps to run as full trust. For more information, see GitHub issue #7766.

Version 1.2.2 (1.2.221209.1)

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.2 release.

- Fixed issue that caused the Store and side-load packages (e.g. from installer, NuGet, and bootstrapper) to fail to install if the other is already installed. For more information, see GitHub issue #3168.
- Fixed issue causing missing elasticity effects and animation curves when scrolling with a touchpad. For more information, see GitHub issue #7874.
- Fixed issue in ListView causing memory leaks.
- Fixed issue causing the Button template to not respect the Foreground property after mouse hover. For more information, see GitHub issue #7208.

- Fixed issue causing an unneeded exception when there is no MediaPlaybackItem in a MediaElement.
- Fixed issue causing a white frame to appear in MediaPlayerElement on content transitions.
- Fixed additional issues causing App.UnhandledException to not catch exceptions from other threads. For more information, see GitHub issues #1259 and #5221.

Version 1.2.1 (1.2.221116.1)

This is a servicing release of the Windows App SDK that includes a critical bug fix for the 1.2 release.

Fixed issue that caused a crash on startup in C++ WinUI 3 apps when adding a WebView2 or TextBox control. For more information see GitHub issues #7911 & #3117.

new and updated features and known issues for version 1.2

The following sections describe new and updated features and known issues for 1.2.

> **Note**
>
> Visual Studio 2019 and .NET 5 is no longer supported for building C# apps (see Windows App SDK 1.2 moving to C# WinRT 2.0). You will need Visual Studio 2022 and one of the following .NET SDK versions: 6.0.401 (or later), 6.0.304, 6.0.109. When released, WinAppSDK 1.2 will support .NET 7 as well.
>
> To update your .NET SDK version, install the latest version of Visual Studio 2022 or visit .NET Downloads. When updating your NuGet package without the required .NET SDK version, you will see an error like: "*This version of WindowsAppSDK requires .NET 6+ and WinRT.Runtime.dll version 2.0 or greater.*". To update the project from .NET 5.0 to .NET 6.0, open the project file and change "TargetFramework" to `net6.0` and "Target OS version" to the appropriate value (such as `net6.0-windows10.0.19041.0`).

Third-party Widgets in Windows

The widgets board was first introduced in Windows 11 and was limited to displaying built-in widgets. Widgets are small UI containers that display text and graphics on the widgets board, and are associated with an app installed on the device. With Windows App SDK, as third party developers you can now create widgets for your packaged Win32 apps and test them locally on the Windows 11 widgets board.

For more information about widgets, check out Widgets Overview.

To get started developing widgets for your app, check out the Widget service providers development docs and Widgets design fundamentals for prerequisites, guidance and best practices.

Prerequisites for this release include:

- Developer mode enabled on the development machine.
- The development machine is running a version of Windows from the Dev Channel of Windows Insider Preview (WIP) that is greater than or equal to 25217 with widgets board version 521.20060.1205.0 or above.

Known limitations when developing Widgets:

- Third-party Widgets can only be tested locally on devices enrolled in WIP for this preview release.
- Widgets can only be created for packaged, Win32 apps. Widgets for Progressive Web Apps (PWA) are planned to be supported as part of Microsoft Edge 108.

DisplayInformation

Windows desktop apps can now support High Dynamic Range (HDR) and Auto Color Management (ACM) through the DisplayInformation class in WinAppSDK. The DisplayInformation class enables you to monitor display-related information for an application view. This includes events to allow clients to monitor for changes in the application view affecting which display(s) the view resides on, as well as changes in displays that can affect the application view.

WinUI 3

WinUI 3 apps can play audio and video with the **MediaPlayerElement** and **MediaTransportControls** media playback controls. For more info on how and when to use media controls, see Media players.

WinUI 3 has been updated with the latest controls, styles, and behaviors from WinUI 2.8. These updates include the addition of the **InfoBadge** control, improvements to

accessibility and high contrast mode, as well as bug fixes across controls. For more details, see the release notes for WinUI 2.7 and WinUI 2.8.

Fixed issues:

- Acrylic backdrop material with DesktopAcrylicController is now supported in Windows 10 apps. For more information, check out issue 7112 on GitHub.
- Fixed various issues that caused routing of App.UnhandledException to fail. For more information, check out issue 5221 on GitHub. Regarding the remaining issues, workarounds are documented at the following GitHub issues and will be resolved in a future 1.2 release:
  - App_UnhandledException's UnhandledExceptionEventArgs.Exception can only be fetched once - should be cached
  - Do_Abi_* event/callback handlers should wrap invocations with RoReportUnhandledError
- Fixed issue causing ListView styles to regress and change from WinAppSDK 1.1. For more information, check out issue 7666 on GitHub.
- Fixed issue causing the incorrect Mica fallback background color to appear when the app is inactive. For more information, check out issue 7801 on GitHub.

Known limitations:

- When creating a new WinUI 3 project with Visual Studio 2022 17.4.0, it will reference a preview version of the WinAppSDK. Use NuGet Package Manager to update the reference to this release.
- Setting MediaPlayerElement.Source to relative URI (ms-appx/ms-resource) fails in unpackaged apps. The recommended workaround is to convert the relative ms-appx:/// URI to a fully resolved file:/// URI.

Trimming for apps developed with .NET

.NET developers can now publish trimmed WinAppSDK apps. With CsWinRT 2.0, the C#/WinRT projections distributed in WinAppSDK are now trimmable. Publishing your app trimmed can reduce the disk footprint of your app by removing any unused code from trimmable binaries. Apps may also see a startup performance improvement. With a basic Hello World app, we have seen a ~80% disk footprint improvement and a ~7% startup performance improvement when published trimmed. With WinUI gallery, we have seen a ~45% disk footprint improvement.

For more details on how to enable trimming, trimming limitations (such as reflection against trimmable types), and trim warnings, see Trim self-contained deployments and

executables. Developers should thoroughly test their apps after trimming to ensure everything works as expected. For more information, check out issue 2478 on GitHub.

Support for Visual Studio Arm64

As early as Project Reunion (now WinAppSDK) 0.5, apps developed with WinAppSDK were able to run on Arm64. Starting with Visual Studio 17.3 Preview 2, you can develop native applications with WinAppSDK on Arm64 devices.

To get started developing on an Arm64 device, see Windows on Arm and Arm64 Visual Studio.

Notifications

AppNotificationBuilder introduced as an alternative to XML payload for creating and defining App Notifications.

For usage information, see the AppNotificationBuilder spec on GitHub.

Also see Quickstart: App notifications in the Windows App SDK for an example of how to create a desktop Windows application that sends and receives local app notifications.

Breaking change:

For push notifications, when making a channel request call, apps will need to use the Azure Object ID instead of the Azure App ID. See Quickstart: Push notification in the Windows App SDK for details on finding your Azure Object ID.

Fixed issue:

PushNotificationManager.IsSupported will perform a check for elevated mode. It will return `false` if the app is elevated.

Known limitations (Notifications):

- In **AppNotificationScenario**, `Urgent` is only supported for Windows builds 19041 and later. You can use **AppNotificationBuilder.IsUrgentScenarioSupported** to check whether the feature is available at runtime.
- In **AppNotificationButton**, `hint-toolTip` and `hint-buttonStyle` are only supported for builds 19041 and later. You can use **IsButtonStyleSupported** and **IsToolTipSupported** to check whether the feature is available at runtime.
- In **MediaPlayerElement**, when used in XAML markup for an unpackaged app, the **Source** property cannot be set with an ms-appx or ms-resource URI. As an alternative, set the Source using a file URI, or set from code.

Windowing

Full title bar customization is now available on Windows 10, version 1809 and later through the **AppWindowTitleBar** class. You can set **AppWindowTitleBar.ExtendsContentIntoTitleBar** to `true` to extend content into the title bar area, and **SetDragRectangles** to define drag regions (in addition to other customization options).

If you've been using the **AppWindowTitleBar.IsCustomizationSupported** property to check whether you can call the **AppWindowTitleBar** APIs, it now returns `true` on supported Windows App SDK Windows 10 versions (1809 and later).

Known limitations (Windowing):

Basic title bar customizations are not supported on Windows 10. These include **BackgroundColor**, **InactiveBackgroundColor**, **ForegroundColor**, **InactiveForegroundColor** and **IconShowOptions**. If you call these properties, they will be ignored silently. All other **AppWindowTitleBar** APIs work in Windows 10, version 1809 and later. For the caption button color APIs (among others) and **Height**, **ExtendsContentIntoTitleBar** must be set to `true`, otherwise they will also be ignored silently.

Access control

Introduced security.accesscontrol.h with the **GetSecurityDescriptorForAppContainerNames** function to ease and streamline named object sharing between packaged processes and general Win32 APIs. This method takes a list of Package Family Names (PFNs) and access masks, and returns a security descriptor. For more information, see the GetSecurityDescriptorForAppContainerNames spec on GitHub.

Other limitations and known issues

> **Important**
>
> When you reference WinAppSDK 1.2 from a project you might see an error similar to: "*Detected package downgrade: Microsoft.Windows.SDK.BuildTools from 10.0.22621.1 to 10.0.22000.194.*", which is caused by incompatible references to the package from the app project and the WinAppSDK package. To resolve this you can update the reference in the project to a more recent and compatible version of Microsoft.Windows.SDK.BuildTools.

- Unit tests may fail with a `REGDB_E_CLASSNOTREG` error in the Tests output pane in Visual Studio. As a workaround, you can add `<WindowsAppContainer>true</WindowsAppContainer>` to your project file.
- .NET PublishSingleFile isn't supported.
- Bootstrapper and Undocked RegFree WinRT auto-initializer defaults is (now) only set for projects that produce an executable (OutputType=Exe or WinExe). This prevents adding auto-initializers into class library DLLs and other non-executables by default.
  - If you need an auto-initializer in a non-executable (e.g. a test DLL loaded by a generic executable that doesn't initialize the Bootstrapper) you can explicitly enable an auto-initializer in your project via `<WindowsAppSdkBootstrapInitialize>true</WindowsAppSdkBootstrapInitialize>` or `<WindowsAppSdkUndockedRegFreeWinRTInitialize>true</WindowsAppSdkUndockedRegFreeWinRTInitialize>`.
- Microsoft.WindowsAppRuntime.Release.Net.dll is always the Arm64 binary and does not work for x86 and x64 apps. When explicitly calling the Bootstrap API do not use the Microsoft.WindowsAppRuntime.Release.Net.dll assembly. As a workaround you can include version constants in this source file distributed with the NuGet package: '..\include\WindowsAppSDK-VersionInfo.cs' or use the auto-initializer.

Stable channel release notes for the Windows App SDK 1.1

Article • 05/23/2024

The stable channel provides releases of the Windows App SDK that are supported for use by apps in production environments. Apps that use the stable release of the Windows App SDK can also be published to the Microsoft Store.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 1.1

The latest available release of the 1.1.x lineage of the stable channel of the Windows App SDK is version 1.1.5. 1.1.x supports all stable channel features (see the **Features available by release channel** section in Windows App SDK release channels).

Version 1.1.5

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.1 release.

Bug fixes (1.1.5)

- Fixed issue where Acrylic does not work if Mica is enabled. For more information, see issue 7200 on GitHub.
- Fixed issue causing apps that depend on the WindowsAppRuntime installer (e.g. unpackaged apps) to fail to run on Windows 10 ARM64 machines. For more information, see issue 2564 on GitHub.

Version 1.1.4

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.1 release.

Bug fixes (1.1.4)

- Fixed regression from 1.0.x causing ListView, TreeView, and other 'List' controls to crash when scrolling with many items. For more information, see issue 7230 on GitHub.
- Fixed issue with DispatcherQueue causing enqueued callbacks to no longer be invoked.
- Fixed issue causing an app crash when calling `DeploymentManager.Initialize` multiple times in same app session.
- Fixed issue causing C# apps to fail to build on Arm64 Visual Studio. For more information, see issue 7140 on GitHub.
- Fixed intermittent crash in XAML imaging code due to incorrect failure handling.
- Fixed memory leak issue when attaching an event handler in ItemsRepeater with a parent UserControl. For more information, see issue 6123 on GitHub.
- Fixed issue causing a build failure in Visual Studio 17.3 when an app project is configured to enable automatic updates of its package when it's sideloaded (i.e. .appinstaller). For more information, see issue 2773.
- Fixed issue causing Store-distributed packaged apps that call Initialize (necessary e.g. for Push) to call it redundantly as DeploymentManager::GetStatus returned `Package Install Needed` when main and singleton packages are already installed. This caused a perf degradation on app launch.
- Fixed issue causing an exception in single instance apps when the cleanup event was intended to be ignored if it couldn't be opened. For more information, see the PR on GitHub.

Version 1.1.3

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.1 release.

Bug fixes (1.1.3)

- Fixed related set of issues where XAML crashes when including a ProgressBar, ProgressRing, PipsPager, PersonPicture, or Expander control in the first page of your app. For more information see issue 7164 on GitHub.
- Fixed issue causing the x64 installer to fail to install the Windows App SDK runtime. For more information see issue 2713 on GitHub.
- Fixed issue causing the WindowsAppRuntime to fail to install if a higher version of the runtime is installed. For more information see discussion 2708 on GitHub.

Version 1.1.2

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.1 release.

Bug fixes (1.1.2)

- Fixed issue where XAML crashes when closing a window while a dialog is open. For more information see issue 1032 on GitHub.
- Added `<auto-generated>` tag in C# files to prevent StyleCop warnings. For more information see issue 4526 on GitHub.
- Fixed issue causing an access violation error and crash when calling MddBootstrapInitialize when the matching framework package isn't installed. For more information see issue 2592 on GitHub.
- Fixed issue where the C# WinUI 3 item templates were missing in Visual Studio. For more information see issue 7148 on GitHub.
- Fixed issue where the WindowsAppRuntime installer fails when run as System user. For more information see issue 2546 on GitHub.

Version 1.1.1

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.1 release.

Bug fixes (1.1.1)

- Fixed issue causing apps to sometimes crash during a drag and drop operation. For more information see issue 7002 on GitHub.
- Fixed issue causing the title bar to disappear when switching AppWindowPresenterKind from FullScreen to Default.

- Fixed issue where Bootstrapper APIs like `ApiInformation.IsPropertyPresent` and `ApiInformation.IsMethodPresent` would cause unhandled exceptions in apps that aren't packaged. For more information see issue 2382 on GitHub.
- Fixed issue causing app freeze when maximizing application with pen input.

New and updated features and known issues for 1.1

The following sections describe new and updated features, limitations, and known issues for 1.1.

> **Note**
>
> For C# developers, one of the following .NET SDK versions (or later) is required: 6.0.202, 6.0.104, 5.0.407, 5.0.213. To update your .NET SDK version, visit .NET Downloads or update to the latest version of Visual Studio. Without the required .NET SDK version, when updating your NuGet package you will see an error like: *"This version of WindowsAppSDK requires WinRT.Runtime.dll version 1.6 or greater."*.

App Lifecycle & Restart

Apps are now able to initiate an explicit restart with specific arguments & state building off of the existing RegisterApplicationRestart API to register with the OS to restart in update, hang & reboot scenarios.

New features:

- Any packaged or unpackaged desktop app can terminate and restart itself on command, and have access to an arbitrary command-line string for the restarted instance using the `AppInstance.Restart()` API.
  - This is a lifted and synchronous version of the UWP `RequestRestartAsync()` API which enables restarting with arguments and returns an `AppRestartFailureReason` if the restart is unsuccessful.
  - Check out the Restart API docs on GitHub for usage & reference information.

WinUI 3

WinUI 3 is the native user experience (UX) framework for Windows App SDK. This release includes new features from WinAppSDK 1.0 as well as several stability improvements from 1.0 & 1.1 preview releases.

New features:

- Mica and Background Acrylic are now available for WinUI 3 applications.
  - For more information about these materials, check out Materials in Windows 11. Check out our sample code for applying Mica in C++ applications at Apply Mica or Acrylic materials in desktop apps for Windows 11 and in C# applications on GitHub as part of the WinUI 3 Gallery.
- First introduced in 1.0.1, we have stabilized and enabled the creation of **multiple windows on the same thread** in WinUI 3 applications. See issue 5918 for more information.

Fixed bugs:

- Fixed issue when using Mica where the app would crash when a window is divided equally by two screens. See issue 7079 on GitHub for more info.
- Fixed issue causing C# apps with WebView2 to crash on launch when the C/C++ Runtime (CRT) isn't installed by upgrading the WebView2 SDK from 1020.46 to 1185.39.
- Fixed issue causing some rounded corners to show a gradient when they should be a solid color. For more information see issue 6076 & issue 6194 on GitHub.
- Fixed issue where updated styles were missing from generic.xaml.
- Fixed layout cycle issue causing an app to crash when scrolling to the end of a ListView. For more information see issue 6218 on GitHub.
- Fixed issue where users are unable to drop an element when drag-and-drop is enabled. For more information see issue 7008 on GitHub.

Known limitations:

- When using a custom title bar, the caption controls do not change color on theme change.
- XAML crashes when a user closes a window while a dialog is open.

Deployment

New features:

- Packaged apps can now force deploy the Windows App SDK runtime packages using the **DeploymentManager.Initialize(DeploymentInitializeOptions) API** or using the --force option with the Windows App Runtime installer.
- There are additional functional extension categories, UnlockedDEHs, available for packaged apps. Check out the 1.1 Preview 3 release notes for more details. These require the Windows App SDK framework package to be installed. See Latest Windows App SDK downloads to install the runtime.

- Self-contained deployment is supported. Check out the Windows App SDK deployment overview for the differences between framework-dependent and self-contained deployment, and how to get started.
- The Bootstrapper API required for apps that don't deploy with MSIX include new options for improved usability and troubleshooting. Please view our documentation for C# apps, Bootstrapper C# APIs and for C++ apps, mddbootstrapheader.h header. For more details, see Use the Windows App SDK runtime for apps packaged with external location or unpackaged.

Known limitations:

- Running the Windows App Runtime installer (WindowsAppRuntimeInstall.exe) requires sideloading to be enabled. See issue 2469 on GitHub for more information.
- Creating an MSIX package through the Visual Studio Project menus can crash Visual Studio in some scenarios. This issue will be fixed in Visual Studio version 17.3 Preview 2 and serviced to 17.2. If you encounter this issue, you can work around it by generating an MSIX from the command line, switching to an unpackaged project, or reverting back to Windows App SDK 1.0.
- Self-contained applications packaged with MSIX are unsupported on 1809 causing app crash on launch.

Elevation

Apps are now able to run with elevated privilege.

Known limitations:

- Elevated support requires the following OS servicing update:
  - Win11 - May 10, 2022—KB5013943 (OS Build 22000.675)
  - Win10 - May 10, 2022—KB5013942 (OS Builds 19042.1706, 19043.1706, and 19044.1706)
- App and Push Notifications for an elevated unpackaged app is not supported.
- Elevated WinUI 3 apps crash when dragging an element during a drag-and-drop interaction.

Environment Variable Manager

Environment Variable Manager is a new API introduced in Windows App SDK 1.1. Environment Variable Manager allows developers to access, and modify environment variables in the process, user, and machine scope from one API surface.

If Environment Variable Manager is used from a packaged application, all environment variable operations are recorded. When the package is removed all environment variable operations are reverted.

New features:

- Get and set environment variables in the process, user, and machine scope.
- Automatic environment variable revert when a package that uses environment variable manager is removed.
- Includes specific APIs for PATH and PATHEXT.

Known limitations:

- Only available on Windows 11

MRT Core

MRT Core is a streamlined version of the modern Windows Resource Management System that is distributed as part of the Windows App SDK.

Fixed issues:

- An issue causing resources not to be indexed by default when a resource file is added using the VS UI is fixed in .NET SDK 6.0.300. If using an older .NET SDK version, please continue to use the workaround documented in 1.0's release notes. See issue 1786 on GitHub for additional information.
- An issue causing the resource URI to not be built correctly in unpackaged C++ WinUI 3 apps was fixed in Visual Studio 2022 17.2. If using an older Visual Studio version, please update Visual Studio to 17.2 to receive this fix.

Known limitations:

- In .NET projects, resource files copy-pasted into the project folder aren't indexed on F5 if the app was already built. As a workaround, rebuild the app. See issue 1503 on GitHub for more info.

For more information, see Manage resources with MRT Core.

Notifications

Developers of packaged (including packaged with external location) and unpackaged apps can now send Windows notifications.

New features:

- Support for app notifications for packaged and unpackaged apps.
  - Developers can send app notifications, also known as toast notifications, locally or from their own cloud service. See App notifications overview.
- Support for push notifications for packaged and unpackaged apps.
  - Developers can send raw notifications and app notifications from their own cloud service. See Push notifications overview.

Known limitations:

- Sending notifications from an elevated app is not supported. `PushNotificationManager::IsSupported()` will not perform a check for elevated mode.

Windowing

For easier programming access to functionality that's implemented in USER32.dll (see Windows and messages), this release surfaces more of that functionality in AppWindow itself.

New features:

- Apps with existing windows have more control over how a window is shown, by calling `AppWindow.ShowOnceWithRequestedStartupState`—the equivalent of `ShowWindow(SW_SHOWDEFAULT)`.
- Apps can show, minimize, or restore a window while specifying whether the window should be activated or not at the time the call is made.
- Apps can now determine specific dimensions for their window's client area size in Win32 coordinates without needing to calculate the non-client area sizing to get a specific client area size.
- Additional WinRT APIs are available to support z-order management of windows based off of SetWindowPos's hWndInsertAfter functionality.
- Apps drawing custom title bars with AppWindowTitleBar.ExtendsContentIntoTitleBar can set a `PreferredTitleBarHeight` option. You now have a choice between a standard height title bar, or a tall title bar that provides more room for interactive content. See Title bar in the Fluent design guidelines for advice about when to use a tall title bar.

Fixed issues:

- When full screen presenter is invoked the first time, the window now fits on the entire screen correctly. See issue 1853 on GitHub for more info.

- Windows created with `AppWindow::GetFromWindowId` have the `OverlappedPresenter` as the default presenter but does not have restrictions in terms of changes to window styles coming from other APIs. Windows created with AppWindow::Create will have the default Presenter guardrails in place from the start. See issue 2049 on GitHub for more info.
- Using the `OverlappedPresenter.SetBorderAndTitlebar` API to hide caption buttons and borders would result in a 1px top border when maximized. This has been resolved. See issue 1693 on GitHub for more info.

Known limitations:

- When using the **AppWindowTitlebar** API to customize the colors of the standard title bar, the icon and text is misaligned compared to the standard title bar. For more info, see GitHub issue 2459.

- When solving GitHub issue 2049 (seen above), we introduced the following bug: if you apply any **AppWindowPresenter** to an **AppWindow** that you've retrieved from **GetFromWindowId**, then change a window style that's being tracked by that Presenter through calling USER32 APIs, and then try to revert back to the window's previous state by re-applying the default Presenter, the result is a window that has no title bar. If you rely on any Presenter in your app, and use calls to USER32 for changing window styles at the time that a non-default Presenter is applied, then you might need to add a workaround to ensure correct window behavior until this bug is serviced. You can use the following code snippet as a template for how to work around the issue:

```
C#

AppWindow m_appWindow;
OverlappedPresenter m_defaultPresenter;

private void EnterFullScreen_Click(object sender, RoutedEventArgs e)
{
    // Capture the default presenter.
    m_defaultPresenter = m_appWindow.Presenter as OverlappedPresenter;

    // Opt in the default overlapped presenter so it can control
various aspects of the AppWindow.
    m_defaultPresenter.IsAlwaysOnTop =
m_defaultPresenter.IsAlwaysOnTop;
    m_defaultPresenter.IsResizable = m_defaultPresenter.IsResizable;
    m_defaultPresenter.IsMinimizable =
m_defaultPresenter.IsMinimizable;
    m_defaultPresenter.IsMaximizable =
m_defaultPresenter.IsMaximizable;

m_defaultPresenter.SetBorderAndTitleBar(m_defaultPresenter.HasBorder,
```

```
m_defaultPresenter.HasTitleBar);

    m_appWindow.SetPresenter(AppWindowPresenterKind.FullScreen);
}

private void ExitFullScreen_Click(object sender, RoutedEventArgs e)
{
    m_appWindow.SetPresenter(AppWindowPresenterKind.Default);
}
```

C#/WinRT

C# Windows Runtime Components, including WinUI custom controls, are now supported. This enables component authors to distribute C#-authored runtime components to any WinRT compatible language (e.g., C++/WinRT). See Walkthrough—Create a C# component with WinUI 3 controls, and consume it from a C++/WinRT app that uses the Windows App SDK and the sample on GitHub to get started.

Other limitations and known issues

- Apps that reference a package that depends on WebView2 (like Microsoft.Identity.Client) fail to build. This is caused by conflicting binaries at build time. See issue 2492 on GitHub for more information.
- Using `dotnet build` with a WinAppSDK C# class library project may see a build error "Microsoft.Build.Packaging.Pri.Tasks.ExpandPriContent task could not be loaded". To resolve this issue set `<EnableMsixTooling>true</EnableMsixTooling>` in your project file.
- The default WinAppSDK templates note that the MaxVersionTested="10.0.19041.0" when it should be "10.0.22000.0". For full support of some features, notably UnlockedDEHs, update the MaxVersionTested to "10.0.22000.0" in your project file.

Stable channel release notes for the Windows App SDK 1.0

Article • 05/23/2024

The stable channel provides releases of the Windows App SDK that are supported for use by apps in production environments. Apps that use the stable release of the Windows App SDK can also be published to the Microsoft Store.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 1.0.4

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.0 release.

Bug fixes (1.0.4)

- Fixed issue causing AppBars, when used as Page.TopAppBar or Page.BottomAppBar to not render on screen.
- Fixed issue where apps with a package name of 12 characters or less that use a WinUI control from MUXControls.dll will immediately crash. For more information, see issue 6360 on GitHub.

- Fixed touch input issues causing problems with keyboard shortcuts and other scenarios. For more information, see issue 6291 on GitHub.
- Fixed issue causing apps packaged with MSIX or deployed as self-contained to fail to deploy.
- Fixed issue causing apps to sometimes crash during a drag and drop operation. For more information see issue 7002 on GitHub.

Version 1.0.3

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.0 release.

Bug fixes (1.0.3)

- Fixed issue causing C# apps with WebView2 to crash on launch when the C/C++ Runtime (CRT) isn't installed.
- Fixed touch input issues causing problems with keyboard shortcuts and other scenarios. For more information, see issue 6291 on GitHub.

Note: We don't usually add functionality in a servicing release, but this release's WebView2 fix required us to update to the latest version of the WebView2 SDK (1020.46 to 1185.39). See Release Notes for the WebView2 SDK for additional information on WebView2 1.0.1185.39 and Distribute your app and the WebView2 Runtime for additional information on the WebView2 Runtime.

Version 1.0.2

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 1.0 release.

Bug fixes (1.0.2)

- Fixed layout cycle issue causing an app to crash when scrolling to the end of a ListView. For more information see issue 6218 on GitHub.
- Fixed issue causing C# apps to crash on launch when the C/C++ Runtime (CRT) isn't installed. However, the CRT is still required for C# apps using WebView2. For more information see issue 2117 on GitHub.
- Fixed issue where applications with Single-project MSIX did not generate a .appinstaller file. For more information see issue 1821 on GitHub.
- Fixed issue where WinUI applications did not support .NET 6 `dotnet build`.

Version 1.0.1

This is a servicing release of the Windows App SDK that includes critical bug fixes and multi-window support for the 1.0 release.

Bug fixes (1.0.1)

- Fixed issue causing the MddBootstrapAutoinitializer to not compile with enabled ImplicitUsings. For more information see issue 1686 on GitHub.
- Fixed issue where focus in WebView2 would be unexpectedly lost causing input and selection issues. For more information, see issue 5615 & issue 5570 on GitHub.
- Fixed issue causing the in-app toolbar in Visual Studio to be unclickable when using a custom title bar in a WinUI 3 app.
- Fixed issue causing Snap Layout to not appear when using a custom title bar in a WinUI 3 app. For more information, see issue 6333 & issue 6246 on GitHub.
- Fixed issue causing an exception when setting Window.ExtendsContentIntoTitleBar property when Window.SetTitlebar has been called with a still-loading UIElement.
- Fixed issue where Single-project MSIX apps did not support `dotnet build`.
- Fixed issue causing unpackaged apps to not install after installing a packaged app. For more information, see issue 1871 on GitHub.
- Fixed issue reducing performance during mouse drag operations.
- Fixed crash when calling GetWindowIdFromWindow() in unpackaged apps. For more information, see discussion 1891 on GitHub.

The limitations and known issues for version 1.0 also apply to version 1.0.1.

Additionally, for apps with custom title bars, we have made changes in this release (and fixed numerous issues) that include fixes to the glass window used for drag&drop operations. The recommendation is to use the default values and behaviors (give them a try!). If your title bar used margins so that the default caption buttons were interactive, we recommend visualizing your drag region by setting the background of your title bar to red and then adjusting the margins to extend the drag region to the caption controls.

New features

We have stabilized and enabled the creation of **multiple windows on the same thread** in WinUI 3 applications. See issue 5918 for more information.

Version 1.0

The following sections describe new and updated features, limitations, and known issues for 1.0.

WinUI 3

WinUI 3 is the native user experience (UX) framework for Windows App SDK. In this release we've added multiple new features from Windows App SDK 0.8 and stabilized issues from 1.0 Preview releases.

New features and updates:

- We've added new controls (PipsPager, Expander, BreadcrumbBar) and updated existing controls to reflect the latest Windows styles from WinUI 2.6.
- Single-project MSIX packaging is supported in WinUI by creating a new application using the "Blank App, Packaged..." template.
- We now support deploying WinUI 3 apps that aren't packaged on Windows versions 1809 and above. Please view Create your first WinUI 3 (Windows App SDK) project for additional information.
- WinUI 3 projects can now set their target version down to Windows 10, version 1809. Previously, they could only be set as low as version 1903.
- In-app toolbar, Hot Reload, & Live Visual Tree for WinUI packaged apps are supported in Visual Studio 2022 Preview 5 and GA.

Important limitations:

- Known issues for **both packaged and unpackaged WinUI applications**:
  - *Run-time error in C++ or C# apps that reference a C++ Windows Runtime Component:*
    - To resolve, add the below target to the end of the Windows Runtime Component's .vcxproj:

XML

```
<Target Name="GetPriIndexName">
<PropertyGroup>
    <!-- Winmd library targets use the default root namespace of the
project for the App package name -->
    <PriIndexName Condition="'$(RootNamespace)' !=
''">$(RootNamespace)</PriIndexName>
    <!-- If RootNamespace is empty fall back to TargetName -->
    <PriIndexName Condition="$(PriIndexName) == ''">$(TargetName)
</PriIndexName>
</PropertyGroup>
</Target>
```

    - The expected error will be similar to *WinRT originate error - 0x80004005 : 'Cannot locate resource from 'ms-appx:///BlankPage.xaml'.'.*

- Known issues for **WinUI applications with Single-project MSIX** (Blank App, Packaged template):
    - *Missing Package & Publish menu item until you restart Visual Studio:* When creating a new app with Single-project MSIX in both Visual Studio 2019 and Visual Studio 2022 using the Blank App, Packaged (WinUI 3 in Desktop) project template, the command to publish the project doesn't appear in the menu until you close and re-open Visual Studio.
    - A C# app with Single-project MSIX will not compile without the "C++ (v14x) Universal Windows Platform Tools" optional component installed. See Install tools for the Windows App SDK for additional information.
    - *Potential run-time error in an app with Single-project MSIX that consumes types defined in a referenced Windows Runtime Component:* To resolve, manually add activatable class entries to the appxmanifest.xml.
        - The expected error in C# applications is "COMException: Class not registered (0x80040154 (REGDB_E_CLASSNOTREG)).
        - The expected error in C++/WinRT applications is "winrt::hresult_class_not_registered".

- Known issues for **WinUI 3 apps that aren't packaged** (unpackaged apps):
    - Some APIs require package identity, and aren't supported in unpackaged apps, such as:
        - ApplicationData
        - StorageFile.GetFileFromApplicationUriAsync
        - StorageFile.CreateStreamedFileFromUriAsync
        - ApiInformation (not supported on Windows 10)
        - Package.Current
        - Any API in the Windows.ApplicationModel.Resources namespace
        - Any API in the Microsoft.Windows.ApplicationModel.Resources namespace

- Known issues for **packaging and deploying WinUI applications**:
    - The `Package` command is not supported in WinUI apps with Single-project MSIX (Blank App, Packaged template). Instead, use the `Package & Publish` command to create an MSIX package.
    - To create a NuGet package from a C# Class Library with the `Pack` command, ensure the active `Configuration` is `Release`.
    - The `Pack` command is not supported in C++ Windows Runtime Components to create a NuGet package.

For more info, or to get started developing with WinUI, see:

- WinUI
- Create your first WinUI 3 (Windows App SDK) project

Windowing

The Windows App SDK provides an AppWindow class that evolves the previous easy-to-use Windows.UI.WindowManagement.AppWindow preview class and makes it available to all Windows apps, including Win32, WPF, and WinForms.

New Features:

- AppWindow is a high-level windowing API that allows for easy-to-use windowing scenarios that integrates well with the Windows user experience and with other apps. Represents a high-level abstraction of a system-managed container of the content of an app. This is the container in which your content is hosted, and represents the entity that users interact with when they resize and move your app on screen. For developers familiar with Win32, the AppWindow can be seen as a high-level abstraction of the HWND.
- DisplayArea represents a high-level abstraction of a HMONITOR, follows the same principles as AppWindow.
- DisplayAreaWatcher allows a developer to observe changes in the display topology and enumerate DisplayAreas currently defined in the system.

For more info, see Manage app windows (Windows App SDK).

Input

These are the input APIs that support WinUI and provide a lower level API surface for developers to achieve more advanced input interactions.

New Features:

- Pointer APIs: PointerPoint, PointerPointProperties, and PointerEventArgs to support retrieving pointer event information with XAML input APIs.
- InputPointerSource API: Represents an object that is registered to report pointer input, and provides pointer cursor and input event handling for XAML's SwapChainPanel API.
- Cursor API: Allows developers to change the cursor bitmap.
- GestureRecognizer API: Allows developers to recognize certain gestures such as drag, hold, and click when given pointer information.

Important limitations:

- All PointerPoint static factory functions have been removed: **GetCurrentPoint**, **GetCurrentPointTransformed**, **GetIntermediatePoints**, and **GetIntermediatePointsTransformed**.
- The Windows App SDK doesn't support retrieving **PointerPoint** objects with pointer IDs. Instead, you can use the **PointerPoint** member function **GetTransformedPoint** to retrieve a transformed version of an existing **PointerPoint** object. For intermediate points, you can use the **PointerEventArgs** member functions **GetIntermediatePoints** and **GetTransformedIntermediatePoints**.
- Direct use of the platform SDK API **Windows.UI.Core.CoreDragOperation** will not work with WinUI applications.
- **PointerPoint** properties **RawPosition** and **ContactRectRaw** were removed because they referred to non-predicted values, which were the same as the normal values in the OS. Use **Position** and **ContactRect** instead. Pointer prediction is now handled with the **Microsoft.UI.Input.PointerPredictor** API object.

App Lifecycle

Most of the App Lifecycle features already exist in the UWP platform, and have been brought into the Windows App SDK for use by desktop app types, especially unpackaged Console apps, Win32 apps, Windows Forms apps, and WPF apps. The Windows App SDK implementation of these features cannot be used in UWP apps, since there are equivalent features in the UWP platform itself.

> **ⓘ Important**
>
> If you're working on a UWP app, then refer to Migrate from UWP to the Windows App SDK.

Non-UWP apps can also be packaged into MSIX packages. While these apps can use some of the Windows App SDK App Lifecycle features, they must use the manifest approach where this is available. For example, they cannot use the Windows App SDK **RegisterForXXXActivation** APIs and must instead register for rich activation via the manifest.

All the constraints for packaged apps also apply to WinUI apps, which are packaged, and there are additional considerations as described below.

Important considerations:

- Rich activation: GetActivatedEventArgs
  - *Unpackaged apps*: Fully usable.

    - *Packaged apps*: Usable, but these apps can also use the platform `GetActivatedEventArgs`. Note that the platform defines Windows.ApplicationModel.AppInstance whereas the Windows App SDK defines Microsoft.Windows.AppLifecycle.AppInstance. And while UWP apps can use the `ActivatedEventArgs` classes, such as `FileActivatedEventArgs` and `LaunchActivatedEventArgs`, apps that use the Windows App SDK AppLifecycle feature must use the interfaces not the classes (e.g, `IFileActivatedEventArgs`, `ILaunchActivatedEventArgs`, and so on).
    - *WinUi apps*: WinUI's App.OnLaunched is given a Microsoft.UI.Xaml.LaunchActivatedEventArgs, whereas the platform `GetActivatedEventArgs` returns a Windows.ApplicationModel.IActivatedEventArgs, and the WindowsAppSDK `GetActivatedEventArgs` returns a Microsoft.Windows.AppLifecycle.AppActivationArguments object which can represent a platform `LaunchActivatedEventArgs`.
    - For more info, see Rich activation with the app lifecycle API.

- Register/Unregister for rich activation
    - *Unpackaged apps*: Fully usable.
    - *Packaged apps*: Not usable use the app's MSIX manifest instead.
    - For more info, see Rich activation with the app lifecycle API.

- Single/Multi-instancing
    - *Unpackaged apps*: Fully usable.
    - *Packaged apps*: Fully usable.
    - *WinUI apps*: If an app wants to detect other instances and redirect an activation, it must do so as early as possible, and before initializing any windows, etc. To enable this, the app must define DISABLE_XAML_GENERATED_MAIN, and write a custom Main (C#) or WinMain (C++) where it can do the detection and redirection.
    - RedirectActivationToAsync is an async call, and you should not wait on an async call if your app is running in an STA. For Windows Forms and C# WinUI apps, you can declare Main to be async, if necessary. For C++ WinUI and C# WPF apps, you cannot declare Main to be async, so instead you need to move the redirect call to another thread to ensure you don't block the STA.
    - For more info, see App instancing with the app lifecycle API.

- Power/State notifications
    - *Unpackaged apps*: Fully usable.
    - *Packaged apps*: Fully usable.
    - For more info, see Power management with the app lifecycle API.

Known issue:

- File Type associations incorrectly encode %1 to be %251 when setting the Verb handler's command line template, which crashes unpackaged Win32 apps. You can manually edit the Registry value to be %1 instead as a partial workaround. If the target file path has a space in it, then it will still fail and there is no workaround for that scenario.
- These Single/Multi-instancing bugs will be fixed in an upcoming servicing patch:
  - AppInstance redirection doesn't work when compiled for x86
  - Registering a key, unregistering it, and re-registering it causes the app to crash

DWriteCore

DWriteCore is the Windows App SDK implementation of DirectWrite, which is the DirectX API for high-quality text rendering, resolution-independent outline fonts, and full Unicode text and layout support. DWriteCore is a form of DirectWrite that runs on versions of Windows down to Windows 10, version 1809 (10.0; Build 17763), and opens the door for you to use it cross-platform.

Features:

DWriteCore contains all of the features of DirectWrite, with a few exceptions.

Important limitations:

- DWriteCore does not contain the following DirectWrite features:
  - Per-session fonts
  - End-user defined character (EUDC) fonts
  - Font-streaming APIs
- Low-level rendering API support is partial.
- DWriteCore doesn't interoperate with Direct2D, but you can use IDWriteGlyphRunAnalysis and IDWriteBitmapRenderTarget.

For more information, see DWriteCore overview.

MRT Core

MRT Core is a streamlined version of the modern Windows Resource Management System that is distributed as part of the Windows App SDK.

Important limitations:

- In .NET projects, resource files copy-pasted into the project folder aren't indexed on F5 if the app was already built. As a workaround, rebuild the app. See issue 1503 for more info.

- In .NET projects, when a resource file is added to the project using the Visual Studio UI, the files may not be indexed by default. See issue 1786 for more info. To work around this issue, please remove the entries below in the CSPROJ file:

  XML

  ```xml
  <ItemGroup>
      <Content Remove="<image file name>" />
  </ItemGroup>
  <ItemGroup>
      <PRIResource Remove="<resw file name>" />
  </ItemGroup>
  ```

- For unpackaged C++ WinUI apps, the resource URI is not built correctly. To work around this issue, add the following in the vcxproj:

  XML

  ```xml
  <!-- Add the following after <Import
  Project="$(VCTargetsPath)\Microsoft.Cpp.props" /> -->

  <PropertyGroup>
      <AppxPriInitialPath></AppxPriInitialPath>
  </PropertyGroup>
  ```

For more information, see Manage resources with MRT Core.

Deployment

New Features and updates:

- You can auto-initialize the Windows App SDK through the `WindowsPackageType project` property to load the Windows App SDK runtime and call the Windows App SDK APIs. See Create your first WinUI 3 (Windows App SDK) project for instructions.
- Unpackaged apps can deploy Windows App SDK by integrating in the standalone Windows App SDK `.exe` installer into your existing MSI or setup program. For more info, see Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged.

- Unpackaged .NET apps can also use .NET wrapper for the bootstrapper API to dynamically take a dependency on the Windows App SDK framework package at run time. For more info about the .NET wrapper, see .NET wrapper library.
- Packaged apps can use the deployment API to verify and ensure that all required packages are installed on the machine. For more info about how the deployment API works, see Windows App SDK deployment guide for framework-dependent packaged apps.

Important limitations:

- The .NET wrapper for the bootstrapper API is only intended for use by unpackaged .NET applications to simplify access to the Windows App SDK.
- Only MSIX packaged apps that are full trust or have the packageManagement restricted capability have the permission to use the deployment API to install the main and singleton package dependencies. Support for partial-trust packaged apps will be coming in later releases.
- When F5 testing an x86 app which uses the DeploymentManager.Initialize method on an x64 system, ensure that the x64 framework is first installed by running the WindowsAppRuntimeInstall.exe. Otherwise, you will encounter a **NOT_FOUND** error due to Visual Studio not deploying the x64 framework, which normally occurs through Store deployment or sideloading.

Other limitations and known issues

- **No support for Any CPU build configuration**: When adding the Windows App SDK to an existing .NET application or component that supports **Any CPU**, you must specify the desired architecture: `x86`, `x64` or `arm64`.

- **Upgrading from .NET 5 to .NET 6**: When upgrading in the Visual Studio UI, you might run into build errors. As a workaround, manually update your project file's `TargetFrameworkPackage` to the below:

  ```
  XML
  <TargetFramework>net8.0-windows10.0.19041.0</TargetFramework>
  ```

- **C# Single-project MSIX app doesn't compile if C++ UWP Tools aren't installed.** If you have a C# Single-project MSIX project, then you'll need to install the **C++ (v14x) Universal Windows Platform Tools** optional component.

- **Subsequent language VSIX fails to install into Visual Studio 2019 when multiple versions of Visual Studio 2019 are installed.** If you have multiple versions of Visual

Studio 2019 installed (e.g. Release and Preview) and then install the Windows App SDK VSIX for both C++ *and* C#, the second installation will fail. To resolve, uninstall the Single-project MSIX Packaging Tools for Visual Studio 2019 after the first language VSIX. View this feedback for additional information about this issue.

- An alternative to **DispatcherQueue.TryEnqueue** (for resuming execution on the dispatcher queue thread) is to use the resume_foreground helper function in the Windows Implementation Library (WIL):

    1. Add a reference to your project to the Microsoft.Windows.ImplementationLibrary NuGet package.
    2. Add `#include <wil/cppwinrt_helpers.h>` to your `pch.h`.
    3. Add `#include <winrt/Microsoft.UI.Dispatching.h>` to your `pch.h`.
    4. Now `co_await wil::resume_foreground(your_dispatcherqueue);`.

Stable channel release notes for the Windows App SDK 0.8

Article • 05/23/2024

The stable channel provides releases of the Windows App SDK that are supported for use by apps in production environments. Apps that use the stable release of the Windows App SDK can also be published to the Microsoft Store.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.

Latest stable channel release:

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 0.8

The latest available release of the 0.8.x lineage of the stable channel of the Windows App SDK is version 0.8.12.

> **Note**
>
> The Windows App SDK was previously known by the code name **Project Reunion**. Some SDK assets in version 0.8 and earlier still use the code name. Some areas of the documentation still use **Project Reunion** when referring to an existing asset or a specified earlier release.

Version 0.8.12

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 0.8.0 release.

> **Note**
>
> For C# developers, one of the following .NET SDK versions is required: 5.0.213, 5.0.407, 6.0.104, 6.0.202 (or later). To update your .NET SDK version, visit .NET Downloads or update to the latest version of Visual Studio. Without the required .NET SDK version, when updating your NuGet package you will see an error like: "*This version of WindowsAppSDK requires WinRT.Runtime.dll version 1.6 or greater.*".

Bug fixes (0.8.12)

- Fixed issue where apps with SwapChainPanel or WebView2 would unpredictably crash due to an access violation.

Version 0.8.11

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 0.8.0 release.

> **Note**
>
> For C# developers, one of the following .NET SDK versions is required: 5.0.213, 5.0.407, 6.0.104, 6.0.202 (or later). To update your .NET SDK version, visit .NET Downloads or update to the latest version of Visual Studio. Without the required .NET SDK version, when updating your NuGet package you will see an error like: "*This version of WindowsAppSDK requires WinRT.Runtime.dll version 1.6 or greater.*".

Bug fixes (0.8.11)

- Fixed regression causing the lost focus event to fire when selecting text using mouse.

Version 0.8.10

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 0.8.0 release.

> **Note**
>
> For C# developers, one of the following .NET SDK versions is required: 5.0.213, 5.0.407, 6.0.104, 6.0.202 (or later). To update your .NET SDK version, visit .NET Downloads or update to the latest version of Visual Studio. Without the required .NET SDK version, when updating your NuGet package you will see an error like: "*This version of WindowsAppSDK requires WinRT.Runtime.dll version 1.6 or greater.*".

Bug fixes (0.8.10)

- Fixed issues causing apps to sometimes crash during a drag and drop operation.

> **Note**
>
> Windows App SDK 0.8.9 was not released. The version released directly after 0.8.8 is 0.8.10.

Version 0.8.8

This is a servicing release of the Windows App SDK that includes critical bug fixes for the 0.8.0 release.

> **Note**
>
> For C# developers, one of the following .NET SDK versions (or later) is required: 6.0.202, 6.0.104, 5.0.407, 5.0.213. To update your .NET SDK version, visit .NET Downloads or update to the latest version of Visual Studio. Without the required .NET SDK version, when updating your NuGet package you will see an error like: "*This version of WindowsAppSDK requires WinRT.Runtime.dll version 1.6 or greater.*".

Bug fixes (0.8.8)

- Fixed touch input issues in TextBox regarding soft keyboard and general interaction. These issues also affected keyboard shortcuts. For more information, see issue 6291 on GitHub.
- Fixed issue where an app window would sometimes show as inactive when active.

- Fixed performance issue caused by UIA (UI Automation) running in external processes.
- Fixed app stability issue with pen input.
- Fixed issue where the render of png icons in a Menu are dramatically delayed because of UIA.

Version 0.8.7

This is a servicing release of the Windows App SDK that includes several performance updates for C#/.NET applications. To update to this version, you'll need to reference the latest Windows SDK package version. To do that, add the property `<WindowsSdkPackageVersion>10.0.<sdk_version>.24</WindowsSdkPackageVersion>` to your `.csproj` file with the SDK version your app is targeting from the `TargetFramework` property. For example:

XML

```
<Project Sdk="Microsoft.NET.Sdk">
   <PropertyGroup>
       <OutputType>WinExe</OutputType>
       <TargetFramework>net8.0-windows10.0.19041.0</TargetFramework>
       <TargetPlatformMinVersion>10.0.17763.0</TargetPlatformMinVersion>
       <WindowsSdkPackageVersion>10.0.19041.24</WindowsSdkPackageVersion>
   <PropertyGroup>
   ...
```

This version of the Windows SDK projection will be available in an upcoming .NET 6 servicing release. After that .NET SDK update is available, you should remove the `<WindowsSdkPackageVersion>` property from your project file.

If you don't set this property, then you'll see an error like: `"Error: This version of Project Reunion requires WinRT.Runtime.dll version 1.6 or greater."`

Version 0.8.6

This is a servicing release of the Windows App SDK that includes several performance improvements for C#/.NET applications for the 0.8.0 release.

To update to this version of Windows App SDK, you will need to have the latest .NET SDK December update installed (see Download .NET and .NET 5 will reach End of Support on May 10, 2022). If you don't have the minimum required version of the .NET SDK installed, then you'll see an error like `"Error: This version of Project Reunion requires WinRT.Runtime.dll version 1.4 or greater."`

Bug Fixes (0.8.6)

For a detailed list of the performance improvements, see the C#/WinRT 1.4.1 release notes.

Version 0.8.5

This is a servicing release of the Windows App SDK that includes more critical bug fixes for the 0.8.0 release.

Bug fixes (0.8.5)

- Fixed issue that was causing WinUI apps using pointer input to crash.
- Fixed issue causing the title bar buttons (min, max, close) to not have rounded corners on Windows 11.
- Fixed issue causing the resizing layout options to not appear when hovering over maximize/restore button on Windows 11.
- Fixed issue causing a crashing exception where creating a PointCollection object. For more information, see issue 971 on Github.

The limitations and known issues for version 0.8 also apply to version 0.8.5, unless marked otherwise in the section below.

Version 0.8.4

This is a servicing release of the Windows App SDK that includes more critical bug fixes for the 0.8.0 release.

Bug fixes (0.8.4)

- Fixes for custom title bars so that ContentDialog doesn't cover it up, and the title bar buttons are rounded.
- Fix for a crash in image processing when the display scale is changed.
- Fixes clipping bugs where UI disappear or clipped incorrectly

The limitations and known issues for version 0.8 also apply to version 0.8.4, unless marked otherwise in the section below.

Version 0.8.3

This is a servicing release of the Windows App SDK that includes more critical bug fixes for the 0.8.0 release.

Bug fixes (0.8.3)

Keyboard focus was being lost when a window was minimized and then restored, requiring a mouse click to restore focus.

The limitations and known issues for version 0.8 also apply to version 0.8.3, unless marked otherwise in the section below.

Version 0.8.2

This is a servicing release of the Windows App SDK that includes more critical bug fixes for the 0.8.0 release.

Bug fixes (0.8.2)

- Windows App SDK and WinUI 3 are now supported in Visual Studio 2022 Preview 2 and later.
- For .NET apps, you may receive the following error when passing in an array of enums: `Object contains non-primitive or non-blittable data.`
- Writing using the HandWriting Panel inside a textbox causes a crash
- Icons/images always load at their 100% scale value rather than based on the monitor scale value
- Garbage collection of **EventSource<T>** causes subsequent failure to unsubscribe handlers (see GitHub issue for more details)
- Security fix – see CVE-2021-34533 for more details.
- SwapChainPanel.CompositionScaleChanged sometimes returning incorrect CompositionScale values after changing display scale

The limitations and known issues for version 0.8 also apply to version 0.8.2, unless marked otherwise in the section below.

Version 0.8.1

This is a servicing release of the Windows App SDK that includes a few critical bug fixes for the 0.8.0 release.

Bug fixes (0.8.1)

- Windows App SDK cannot run on the latest Windows Insider build
- Crash in EditableComboBox when entering a value that does not appear in dropdown
- WebView2 doesn't allow user to tab out once focused has been received
- Fully qualify Windows.Foundation.Metadata.DefaultOverload namespace in WinUI generated code to avoid namespace ambiguity
  - This fixes bug #5108.
- Security fix – see CVE-2021-34489 for more details.

The limitations and known issues for version 0.8 also apply to version 0.8.1, unless marked otherwise in the section below.

Version 0.8.0 Stable

New features and updates

This release supports all stable channel features.

WinUI 3:

This release includes many bug fixes and improved stabilization across WinUI 3. These are all of the new changes in WinUI 3 since the release of WinUI 3 - Project Reunion 0.5:

- The Pivot control has been added back in and can now be used in any WinUI 3 app.

- All bug fixes from Project Reunion v0.5.5, v0.5.6, and v0.5.7 are included with this release.

- New bug fixes, including:
  - Mouse right-click in TextBox crashes the application
  - NavigationView causes crash in UWP, Reunion 0.5 Preview
  - ProgressBar doesn't show difference between Paused and Error option
  - Crash in RichEditBox when copying/pasting/changing text style
  - Window caption buttons are misplaced when SetTitleBar is not set or null

  For the full list of bugs addressed in this release, see our GitHub repo.

- The `ColorHelper.ToDisplayName` API is no longer available.

- The following types have been removed:
  - `Microsoft.Graphics.IGeometrySource2D`
  - `Microsoft.Graphics.IGeometrySource2DInterop`

Use `Windows.Graphics.IGeometrySource2D` and `Windows.Graphics.IGeometrySource2DInterop` instead.

- All types in the `Microsoft.System` namespace have been moved to the `Microsoft.UI.Dispatching` namespace, including the DispatcherQueue class.
- The `AcrylicBrush.BackgroundSource` property has been removed, since `HostBackdrop` is not supported as a `BackgroundSource` in WinUI 3.

For more information on WinUI, see WinUI.

To see WinUI 3 controls and features in action, you can clone and build the WinUI 3 Gallery app from GitHub, or download the app from the Microsoft Store.

To get started developing with WinUI, check out the following articles:

- WinUI 3 templates in Visual Studio
- Create your first WinUI 3 (Windows App SDK) project
- Build a C# .NET app with WinUI 3 and Win32 interop
- WinUI 3 API Reference

DWriteCore:

This release of DWriteCore includes the following new and updated features. DWriteCore is introduced and described in the DWriteCore overview.

- DWriteCore now has support for underline—see **IDWriteTextLayout::GetUnderline** and **IDWriteTextLayout::SetUnderline**.
- Support for strikethrough—see **IDWriteTextLayout::GetStrikethrough** and **IDWriteTextLayout::SetStrikethrough**.
- Support for vertical text via **IDWriteTextLayout**—see Vertical text.
- All of the methods of the **IDWriteTextAnalyzer** and **IDWriteTextAnalyzer1** interfaces are implemented.
- The **DWriteCoreCreateFactory** free function creates a factory object that is used for subsequent creation of individual DWriteCore objects.

> **Note**
>
> DWriteCoreCreateFactory is functionally the same as the DWriteCreateFactory function exported by the system version of DirectWrite. The DWriteCore function has a different name to avoid ambiguity in the event that you link both `DWriteCore.lib` and `DWrite.lib`.

For DWriteCore and DirectWrite API reference, see DWriteCore API Reference and DirectWrite API Reference.

MRTCore:

- The **Build Action** for resources is automatically set when you add the resource to your project, reducing the need for manual project configuration.

Limitations

- This release is not currently supported on the Dev Channel of the Windows Insider Program. **This is fixed in version 0.8.1**.
- Desktop apps (C# or C++ desktop): This release is supported for use only in desktop apps (C++ or C#) that are packaged using MSIX. To use the Windows App SDK in unpackaged desktop apps, you must use the experimental release channel.

> **Important**
>
> If you're working on a UWP app, then refer to **Migrate from UWP to the Windows App SDK**.

Known issues

- WinUI 3 tooling such as Live Visual Tree, Live Property Explorer, and Hot Reload in version 0.8 and later requires Visual Studio 2019 16.11 Preview 3 and later.
- Apps currently using WinUI 3 and the Windows App SDK 0.8 cannot use class libraries that use Project Reunion 0.5. Update the class libraries to use the Windows App SDK 0.8.
- .NET apps must target build 18362 or later: Your TFM must be set to net6.0-windows10.0.18362 or later, and your packaging project's must be set to 18362 or later. For more info, see GitHub issue #921.
- You may encounter a crash when switching frequently between light and dark mode.
- For .NET apps, you may receive the following error when passing in an array of enums: `Object contains non-primitive or non-blittable data.` **This is fixed in version 0.8.2**.

- For .NET apps, there is currently no way to opt out of an image getting indexed as an app resource using the Visual Studio UI. To work around this, add a Directory.Build.targets (see Customize your build - Visual Studio for instructions) to the project and remove the image(s) as follows:
    - To remove specific images (note that the relative path is needed):

      XML

      ```
      <Project>
      <ItemGroup>
          <Content Remove="..\Bitmap1.bmp" />
      </ItemGroup>
      </Project>
      ```

    - To remove images based on metadata:

      XML

      ```
      <Project>
      <ItemGroup>
          <Content Remove="@(None->WithMetadataValue('Pack','true'))" />
      </ItemGroup>
      </Project>
      ```

    A fix for this issue is planned for an upcoming release - at that point, the above workarounds will no longer be needed.

Downloads for the Windows App SDK

> **Note**
>
> The Windows App SDK Visual Studio Extensions (VSIX) are no longer distributed as a separate download. They are available in the Visual Studio Marketplace inside Visual Studio.

Version 0.5

The latest available release of the 0.5.x lineage of the stable channel of the Windows App SDK is version 0.5.9.

Download

New features and updates

This release supports all stable channel features.

Known issues and limitations

This release has the following limitations and known issues:

- **Desktop apps (C# or C++ desktop)**: This release is supported for use only in desktop apps (C++ or C#) that are packaged using MSIX. To use the Windows App SDK in unpackaged desktop apps, you must use the experimental release channel.
- **.NET apps must target build 18362 or later**: Your TFM must be set to `net6.0-windows10.0.18362` or later, and your packaging project's `<TargetPlatformVersion>` must be set to 18362 or later. For more info, see the known issue on GitHub.

> **Important**
>
> If you're working on a UWP app, then refer to **Migrate from UWP to the Windows App SDK**.

Preview channel release notes for the Windows App SDK 1.5

Article • 08/13/2024

> **ⓘ Important**
>
> The preview channel is **not supported** for use in production environments, and apps that use the preview releases cannot be published to the Microsoft Store.

The preview channel includes releases of the Windows App SDK with preview channel features in late stages of development. Preview releases do not include experimental features and APIs but may still be subject to breaking changes before the next stable release.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on preview releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest preview channel release:

- Latest preview channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.5 Preview 1 (1.5.0-preview1)

This is the latest release of the preview channel for version 1.5.

In an existing Windows App SDK 1.4 (from the stable channel) app, you can update your Nuget package to 1.5.0-preview1 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Downloads for the Windows App SDK.

XAML Islands runtime and shutdown updates

- There is a behavioral difference between WinAppSDK 1.4 and WinAppSDK 1.5 for Xaml Islands-based apps when the last Xaml Window on any thread is closed.
  - In WinAppSDK 1.4, the Xaml runtime always exits the thread's event loop when the last Xaml window on a thread is closed.
  - In WinAppSDK 1.5:
    - If your app is a WinUI Desktop app, the default behavior is still the same as in WinAppSDK 1.4.
    - If you're using Xaml for the DesktopWindowXamlSource ("Xaml Islands") API, the default behavior is now that Xaml does not automatically exit the thread's event loop.
    - In both modes, you can change this behavior by setting the `Application.DispatcherShutdownMode` property.
  - For more information, see the documentation for the `Application.DispatcherShutdownMode` property when available.
- There is a behavioral difference between WinAppSDK 1.4 and WinAppSDK 1.5 for Xaml Islands-based apps in the lifetime of the Xaml runtime:
  - In WinAppSDK 1.4, the Xaml runtime shuts down on a thread if either all `WindowsXamlManager` and `DesktopWindowXamlSource` objects on a given thread are closed or shut down, or the `DispatcherQueue` running on that thread is shut down (the Xaml runtime shuts down during the `DispatcherQueue.FrameworkShutdownStarting` stage).
  - In WinAppSDK 1.5, the Xaml runtime shuts down on a thread only when the DispatcherQueue running on that thread is shut down (the Xaml runtime shuts down during the `DispatcherQueue.FrameworkShutdownStarting` stage).
  - For more information, see the documentation for the `WindowsXamlManager` class when available.

WinUI Maps control

The initial release of the WinUI `Maps` control is now available! This control is powered by WebView2 and Azure Maps, providing the following features:

- Panning and zooming with either the map buttons or touch.
- Changing the style of the map to satellite, terrain, or street view.
- Programmatically adding interactable pins with developer-customizable icons to the map.
- Developer customization for where the map is centered on initial load.
- Control for developers over hiding or showing the buttons for panning, zooming, and map styles.

> **Note**
>
> To use the `Maps` control, you'll need an Azure Maps key. To create the key, see the Azure Maps documentation page for creating a web app.

The `Maps` control is entirely new and we welcome your feedback to evaluate its future direction!

Other new features from across the WinAppSDK

- Added support for the PublishSingleFile deployment model. For more info about PublishSingleFile, see the Single-file deployment documentation.

Bug fixes

- Fixed an issue from the 1.5-experimental2 release where the projection DLL was not generated. For more info, see GitHub issue #4152.
- Fixed an issue where the ellipsis button on the text formatting popup of the `RichEditBox` was not displaying the list of actions properly. For more info, see GitHub issue #9140.
- Fixed an issue where `ListView` didn't handle keyboard accelerators properly. For more info, see GitHub issue #8063.
- Fixed an access violation issue with using `AccessKey` to close a window. For more info, see GitHub issue #8648.
- Fixed an issue affecting text alignment in a `MenuFlyoutItem` within a `MenuBar`. For more info, see GitHub issue #8755.
- Fixed an issue where highlighted text would not remain highlighted upon right-click. For more info, see GitHub issue #1801.
- Fixed an issue causing inactive windows to crash the app when closed. For more info, see GitHub issue #8913.
- Fixed an issue that could hang applications when scrolling with the middle mouse button and left-clicking immediately afterwards. For more info, see GitHub issue #9233.

New APIs in 1.5.0-preview1

Version 1.5-preview1 includes the following new APIs compared to the stable 1.4 release:

C#

```
Microsoft.Graphics.DirectX

    DirectXPixelFormat
        A4B4G4R4
```

C#

```
Microsoft.UI.Input

    FocusNavigationReason
    FocusNavigationRequest
    FocusNavigationRequestEventArgs
    FocusNavigationResult
    InputFocusController
        DepartFocus
        NavigateFocusRequested

    InputFocusNavigationHost
```

C#

```
Microsoft.UI.Xaml

    Application
        DispatcherShutdownMode

    DebugSettings
        LayoutCycleDebugBreakLevel
        LayoutCycleTracingLevel

    DispatcherShutdownMode
    LayoutCycleDebugBreakLevel
    LayoutCycleTracingLevel
```

C#

```
Microsoft.UI.Xaml.Controls

    MapControl
    MapControlMapServiceErrorOccurredEventArgs
    MapElement
    MapElementClickEventArgs
    MapElementsLayer
    MapIcon
    MapLayer
    SelectorBar
    SelectorBarItem
    SelectorBarSelectionChangedEventArgs
```

```
    WebView2
        EnsureCoreWebView2Async
        EnsureCoreWebView2Async
```

C#

```
Microsoft.UI.Xaml.Hosting

    WindowsXamlManager
        GetForCurrentThread
        XamlShutdownCompletedOnThread

    XamlShutdownCompletedOnThreadEventArgs
```

C#

```
Microsoft.Web.WebView2.Core

    CoreWebView2
        FrameId

    CoreWebView2AcceleratorKeyPressedEventArgs
        IsBrowserAcceleratorKeyEnabled

    CoreWebView2BrowserExtension
    CoreWebView2BrowsingDataKinds
        ServiceWorkers

    CoreWebView2CustomSchemeRegistration
        CoreWebView2CustomSchemeRegistration (String)
        AllowedOrigins
        SchemeName

    CoreWebView2Environment
        GetProcessExtendedInfosAsync

    CoreWebView2EnvironmentOptions
        AreBrowserExtensionsEnabled
        CustomSchemeRegistrations

    CoreWebView2Frame
        FrameId

    CoreWebView2FrameInfo
        FrameId
        FrameKind
        ParentFrameInfo

    CoreWebView2FrameKind
    CoreWebView2MouseEventKind
        NonClientRightButtonDown
        NonClientRightButtonUp
```

```
    CoreWebView2NavigationKind
    CoreWebView2NavigationStartingEventArgs
        NavigationKind

    CoreWebView2NewWindowRequestedEventArgs
        OriginalSourceFrameInfo

    CoreWebView2ProcessExtendedInfo
    CoreWebView2Profile
        AddBrowserExtensionAsync
        Delete
        Deleted
```

C#

```
Microsoft.Windows.Management.Deployment

    AddPackageOptions
    EnsureReadyOptions
    PackageDeploymentContract
    PackageDeploymentManager
    PackageDeploymentProgress
    PackageDeploymentProgressStatus
    PackageDeploymentResult
    PackageDeploymentStatus
    PackageRuntimeManager
    PackageSet
    PackageSetItem
    PackageSetItemRuntimeDisposition
    PackageSetRuntimeDisposition
    PackageVolume

Preview channel release notes for the Windows App SDK 1.4

Article • 05/23/2024

> **ⓘ Important**
>
> The preview channel is **not supported** for use in production environments, and apps that use the preview releases cannot be published to the Microsoft Store.

The preview channel includes releases of the Windows App SDK with preview channel features in late stages of development. Preview releases do not include experimental features and APIs but may still be subject to breaking changes before the next stable release.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on preview releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest preview channel release:

- Latest preview channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.4 Preview 2 (1.4.0-preview2)

This is the latest release of the preview channel for version 1.4.

In an existing Windows App SDK 1.3 (from the stable channel) app, you can update your Nuget package to 1.4.0-preview2 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Latest Windows App SDK downloads.

XAML Islands no longer experimental

XAML Islands and the underlying ContentIslands platform are no longer experimental.

- Currently XAML Islands are only tested for use in C++ apps. This release does not include any convenient wrapper elements for use in WPF or WinForms.
- `DesktopWindowXamlSource` and related types have been added in the Microsoft.UI.Xaml.Hosting namespace for XAML Islands. `XamlRoot.ContentIslandEnvironment` was added to help access the underlying Island information for an element.
- Many new types have been introduced in the Microsoft.UI.Content namespace and the Microsoft.UI.Input namespace as the underlying support for XAML Islands or for using this ContentIslands functionality without XAML.
- A new `DragDropManager` (plus related types) has been added in the Microsoft.UI.Input.DragDrop namespace for Island scenarios.

ItemsView updates

The new `ItemsView` class that was introduced in version 1.4-preview1 has been substantially updated with new properties and a new supporting class.

- The new `ItemsView` control displays a data collection. `ItemsView` is similar to the `ListView` and `GridView` controls, but is built using the `ItemsRepeater`, `ScrollView`, `ItemContainer` and `ItemCollectionTransitionProvider` components. It offers the unique ability to plug in custom `Layout` or `ItemCollectionTransitionProvider` implementations. Another key advantage is the ability to switch the layout on the fly while preserving items selection. The inner `ScrollView` control also offers features unavailable in `ListView`/`GridView`'s `ScrollViewer` control such as the ability to control the animation during programmatic scrolls.
  - A new `ItemTransitionProvider` property on `ItemsRepeater` (and the new `ItemsView` control) lets you specify an `ItemCollectionTransitionProvider` object to control transition animations on that control. A `CreateDefaultItemTransitionProvider` method has also been added to `Layout`, which enables a layout object to provide a fallback transition to accompany it if you do not provide one explicitly on the `ItemsView` control.
  - A new `IndexBasedLayoutOrientation` property on `Layout` where the layout orientation, if any, of items is based on their index in the source collection. The default value is `IndexBasedLayoutOrientation.None`. Custom layouts set this property by calling the new (protected) `SetIndexBasedLayoutOrientation` method.
  - A new `VisibleRect` property on `VirtualizingLayoutContext` gets the visible viewport rectangle within the `FrameworkElement` associated with the `Layout`. The

protected virtual `VirtualizingLayoutContext.VisibleRectCore` method can be overridden to provide the value that will be returned from the `VisibleRect` property.

- The new `LinedFlowLayout` class is typically used to lay out the items of the `ItemsView` collection control. It is particularly useful for displaying collection of pictures. It does so by laying them out from left to right, and top to bottom, in lines of equal height. The pictures fill a horizontal line and then wrap to a next line. Pictures may be cropped at the left and right edges to fit into a line. They may also be expanded horizontally and cropped at the top and bottom edges to fill a line when the stretching mode is employed.

New features and updates from across the WinAppSDK

- `Popup/FlyoutBase.IsConstrainedToRootBounds = false` is now supported, allowing a popup/flyout to extend outside the bounds of the parent window. A `SystemBackdrop` property has been added to these types to support having acrylic in these unconstrained popups. Menus by default use this to have acrylic.
- `Closed`, `FrameworkClosed`, and `IsClosed` have been added to `DesktopAcrylicController` and `MicaController` to improve handling during object/thread shutdown.
- `DesktopAcrylicController.Kind` can now be set to choose between some standard acrylic appearances.
- `DispatcherQueue` has some new events and helpers to facilitate better organized shutdown and for apps using Islands to easily run a standard supported event loop.
- `InputNonClientPointerSource` in the Microsoft.UI.Input namespace can be used for custom titlebar scenarios to define non-client area regions. Code can register for corresponding events like hover and click events on these regions.
- `AppWindow` has some new helpers to get and associate with a `DispatcherQueue`.
- The new `TreeView.SelectionChanged` event allows developers to respond when the user or code-behind changes the set of selected nodes in the `TreeView` control.
- The new `ScrollView` control provides a new alternative to `ScrollViewer`. This new control is highly aligned in behavior and API with the existing `ScrollViewer` control, but is based on `InteractionTracker`, has new features such as animation-driven view changes, and is also designed to ensure full functionality of `ItemsRepeater`. See A more flexible ScrollViewer · Issue #108 · microsoft/microsoft-ui-xaml (github.com) for more details. Various new types, including `ScrollPresenter`, are part of the overall `ScrollView` model.

- The new `AnnotatedScrollBar` control extends a regular scrollbar's functionality by providing an easy way to navigate through a large collection of items. This is achieved through a clickable rail with labels that act as markers. It also allows for a more granular understanding of the scrollable content by displaying a tooltip when hovering over the clickable rail.

New APIs in 1.4.0-preview2

Version 1.4-preview2 includes the following new APIs compared to the previous 1.4-preview1 release:

C#

```
Microsoft.UI

    ClosableNotifierHandler
    IClosableNotifier
```

C#

```
Microsoft.UI.Composition.SystemBackdrops

    DesktopAcrylicController
        Closed
        FrameworkClosed
        IsClosed
        Kind

    DesktopAcrylicKind
    MicaController
        Closed
        FrameworkClosed
        IsClosed
```

C#

```
Microsoft.UI.Content

    ContentCoordinateConverter
    ContentCoordinateRoundingMode
    ContentDeferral
    ContentEnvironmentSettingChangedEventArgs
    ContentEnvironmentStateChangedEventArgs
    ContentIsland
    ContentIslandAutomationProviderRequestedEventArgs
    ContentIslandEnvironment
    ContentIslandStateChangedEventArgs
    ContentLayoutDirection
```

```
    ContentSite
    ContentSiteEnvironment
    ContentSiteEnvironmentView
    ContentSiteRequestedStateChangedEventArgs
    ContentSiteView
    ContentSizePolicy
    DesktopChildSiteBridge
    DesktopSiteBridge
    IContentSiteBridge
```

C#

```
Microsoft.UI.Dispatching

    DispatcherExitDeferral
    DispatcherQueue
        EnqueueEventLoopExit
        EnsureSystemDispatcherQueue
        FrameworkShutdownCompleted
        FrameworkShutdownStarting
        RunEventLoop
        RunEventLoop

    DispatcherQueueController
        ShutdownQueue

    DispatcherRunOptions
```

C#

```
Microsoft.UI.Input

    CharacterReceivedEventArgs
    ContextMenuKeyEventArgs
    FocusChangedEventArgs
    InputActivationListener
        GetForIsland

    InputFocusChangedEventArgs
    InputFocusController
    InputKeyboardSource
        CharacterReceived
        ContextMenuKey
        GetCurrentKeyState
        GetForIsland
        GetKeyState
        KeyDown
        KeyUp
        SystemKeyDown
        SystemKeyUp

    InputNonClientPointerSource
```

```
    InputPointerSource
        GetForIsland

    InputPreTranslateKeyboardSource
    KeyEventArgs
    NonClientCaptionTappedEventArgs
    NonClientPointerEventArgs
    NonClientRegionKind
    NonClientRegionsChangedEventArgs
    PhysicalKeyStatus
    VirtualKeyStates
```

C#

```
Microsoft.UI.Input.DragDrop

    DragDropManager
    DragDropModifiers
    DragInfo
    DragOperation
    DragUIContentMode
    DragUIOverride
    DropOperationTargetRequestedEventArgs
    IDropOperationTarget
```

C#

```
Microsoft.UI.Windowing

    AppWindow
        AssociateWithDispatcherQueue
        Create
        DispatcherQueue
```

C#

```
Microsoft.UI.Xaml

    XamlRoot
        ContentIslandEnvironment
```

C#

```
Microsoft.UI.Xaml.Automation.Peers

    ItemsViewAutomationPeer
```

C#

    DesktopWindowXamlSourceGotFocusEventArgs
    DesktopWindowXamlSourceTakeFocusRequestedEventArgs
    WindowsXamlManager
    XamlSourceFocusNavigationReason
    XamlSourceFocusNavigationRequest
    XamlSourceFocusNavigationResult
```

Version 1.4 Preview 1 (1.4.0-preview1)

This is the latest release of the preview channel for version 1.4.

In an existing Windows App SDK 1.3 (from the stable channel) app, you can update your Nuget package to 1.4.0-preview1 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Latest Windows App SDK downloads.

Widgets updates

Three new interfaces have been added for Widget Providers to implement: `IWidgetProvider2`, `IWidgetProviderAnalytics`, and `IWidgetProviderErrors`. `IWidgetProvider2` allows providers to respond to the *Customize* action invoked by the user, which is identical to what is available for 1st party Widgets. The `IWidgetProviderAnalytics` and `IWidgetProviderErrors` interfaces are used by providers to gather telemetry for their widgets; analytics and failure events about widgets are communicated to the respective widget providers. The `WidgetCustomizationRequestedArgs`, `WidgetAnalyticsInfoReportedArgs`, and `WidgetErrorInfoReportedArgs` classes are used to communicate relevant information to support new functionalities.

New features from across the WinAppSDK

- A new `ThemeSettings` class that allows Win32 WinRT apps to detect when the system's High Contrast setting has changed, similar to UWP's AccessibilitySettings class. See the ThemeSettings API spec on GitHub for more information.
- `Popup/FlyoutBase.ShouldConstrainToRootBounds` is now supported to allow tooltips, menus, and other popups to extend outside the bounds of the main window. Preview 1 does not yet fully support having Acrylic or other SystemBackdrops on a popup/flyout; additional APIs and implementation for this will be included in the next 1.4 release.
- `AccessKeyManager.EnterDisplayMode` is a new method to display access keys for the current focused element of a provided root. Access keys are in "display mode" when showing a key tip to invoke a command, such as pressing the Alt key in Paint to show what keys correspond to what controls. This method allows for programmatically entering display mode.
- `Application.ResourceManagerRequested` provides a mechanism to provide a different `IResourceManager` to resolve resource URIs for scenarios when the default `ResourceManager` won't work. For more information, see the Application.ResourceManagerRequested API spec on GitHub.
- We're introducing a new list control called the `ItemsView` and a corresponding concrete `ItemContainer` class. `ItemContainer` is a lightweight container with built-

in selection states and visuals, which can easily wrap desired content and be used with `ItemsView` for a collection control scenario. `ItemsView` is still marked experimental in Preview 1 but will be included in the next 1.4 release.
- The version of the WebView2 SDK was updated from 1661.34 to 1823.32.

New APIs in 1.4.0-preview1

Version 1.4-preview1 includes the following new APIs compared to the stable 1.3 release:

```
C#
```

```
Microsoft.UI.System

    ThemeSettings
```

```
C#
```

```
Microsoft.UI.Xaml

    Application
        ResourceManagerRequested

    ResourceManagerRequestedEventArgs
```

```
C#
```

```
Microsoft.UI.Xaml.Automation.Peers

    ItemContainerAutomationPeer
```

```
C#
```

```
Microsoft.UI.Xaml.Controls

    ItemContainer
```

```
C#
```

```
Microsoft.UI.Xaml.Controls.Primitives

    CommandBarFlyoutCommandBar
        SystemBackdrop
        SystemBackdropProperty
```

C#

```
Microsoft.UI.Xaml.Input

    AccessKeyManager
        EnterDisplayMode
```

C#

```
Microsoft.Web.WebView2.Core

    CoreWebView2
        LaunchingExternalUriScheme
        MemoryUsageTargetLevel

    CoreWebView2File
    CoreWebView2LaunchingExternalUriSchemeEventArgs
    CoreWebView2MemoryUsageTargetLevel
    CoreWebView2PermissionKind
        WindowManagement

    CoreWebView2Profile
        CookieManager
        IsGeneralAutofillEnabled
        IsPasswordAutosaveEnabled

    CoreWebView2Settings
        IsReputationCheckingRequired

    CoreWebView2WebMessageReceivedEventArgs
        AdditionalObjects
```

C#

```
Microsoft.Windows.Widgets.Providers

    IWidgetProvider2
    IWidgetProviderAnalytics
    IWidgetProviderErrors
    WidgetAnalyticsInfoReportedArgs
    WidgetCustomizationRequestedArgs
    WidgetErrorInfoReportedArgs
```

Preview channel release notes for the Windows App SDK 1.3

Article • 05/23/2024

> **ⓘ Important**
>
> The preview channel is **not supported** for use in production environments, and apps that use the preview releases cannot be published to the Microsoft Store.

The preview channel includes releases of the Windows App SDK with preview channel features in late stages of development. Preview releases do not include experimental features and APIs but may still be subject to breaking changes before the next stable release.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on preview releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest preview channel release:

- Latest preview channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.3 Preview 1 (1.3.0-preview1)

This is the latest release of the preview channel for version 1.3. This release includes previews for new features across WinAppSDK and several performance, security, accessibility and reliability bug fixes.

In an existing Windows App SDK 1.2 (from the stable channel) app, you can update your Nuget package to 1.3.0-preview1 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Latest Windows App SDK downloads.

XAML Backdrop APIs

With properties built in to the XAML Window, Mica & Background Acrylic backdrops are now easier to use in your WinUI 3 app.

See the Xaml Backdrop API spec on GitHub for more information about the **Window.SystemBackdrop** property.

```
C#

public MainWindow()
{
    this.InitializeComponent();

    this.SystemBackdrop = new MicaBackdrop();
}
```

Window.AppWindow

Replacing several lines of boilerplate code, you're now able to use AppWindow APIs directly from a **Window** through `Window.AppWindow`. See the Window.AppWindow API spec on GitHub for additional background and usage information.

New features from across WinAppSDK

- `ApplicationModel.DynamicDependency`: `PackageDependency.PackageGraphRevisionId` that replaces the deprecated MddGetGenerationId.
- Environment Manager: `EnvironmentManager.AreChangesTracked` to inform you whether changes to the environment manager are able to be tracked in your application. See the Environment Manager API spec on GitHub for more information.
- MRT Core: A new event, `Application.ResourceManagerInitializing` allows your app to provide its own implementation of the `IResourceManager` interface, and gives you access to the ResourceManager that WinUI uses to resolve resource URIs. See the IResourceManager API spec on GitHub for more information.
- With the latest experimental VSIX, you're now able to convert your app between unpackaged and packaged through the Visual Studio menu instead of in your project file.
- A new event, `DebugSettings.XamlResourceReferenceFailed` is now raised when a referenced Static/ThemeResource lookup can't be resolved. This event gives access to a trace that details where the framework searched for that key in order to better

enable you to debug Static & ThemeResource lookup failures. For more information, see the API spec and issues 4972, 2350, and 6073 on GitHub.

- Deployment: To manage and repair the Windows App Runtime, `DeploymentRepairOptions` is now available as part of the `DeploymentManager`. For more information, see the Repair section of the Deployment API Spec on GitHub.

Known issues

- The Pivot control causes a runtime crash with a XAML parsing error. See issue #8160 on GitHub for more info.
- When the DatePicker or TimePicker flyout is opened, the app crashes.
- The `WindowsAppRuntime.ReleaseInfo` and `WindowsAppRuntime.RuntimeInfo` APIs introduced in 1.3 releases are not yet supported as they contain a critical bug.

Preview channel release notes for the Windows App SDK 1.2

Article • 05/23/2024

> **ⓘ Important**
>
> The preview channel is **not supported** for use in production environments, and apps that use the preview releases cannot be published to the Microsoft Store.

The preview channel includes releases of the Windows App SDK with preview channel features in late stages of development. Preview releases do not include experimental features and APIs but may still be subject to breaking changes before the next stable release.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on preview releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest preview channel release:

- Latest preview channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.2 Preview 2 (1.2.0-preview2)

This is the latest release of the preview channel for version 1.2.

In an existing Windows App SDK 1.1 (from the stable channel) app, you can update your Nuget package to 1.2.0-preview2 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Latest Windows App SDK downloads.

> **ⓘ Important**

Visual Studio 2019 and .NET 5 is no longer supported for building C# apps (see **Windows App SDK 1.2 moving to C# WinRT 2.0**). You will need Visual Studio 2022 and one of the following .NET SDK versions: 6.0.401 (or later), 6.0.304, 6.0.109.

To update your .NET SDK version, install the latest version of Visual Studio 2022 or visit **.NET Downloads**. When updating your NuGet package without the required .NET SDK version, you will see an error like: "*This version of WindowsAppSDK requires .NET 6+ and WinRT.Runtime.dll version 2.0 or greater.*". To update the project from .NET 5.0 to .NET 6.0, open the project file and change "TargetFramework" to `net6.0` and "Target OS version" to the appropriate value (such as `net6.0-windows10.0.19041.0`).

Third-party Widgets in Windows

The Widgets Board was first introduced in Windows 11 and was limited to displaying first party Widgets. Widgets are small UI containers that display text and graphics on the Widgets Board, and are associated with an app installed on the device. With Windows App SDK, as third party developers you can now create Widgets for your packaged Win32 apps and test them locally on the Windows 11 Widgets Board.

For more information about Widgets, check out Widgets overview.

To get started developing Widgets for your app, check out the Widget providers development docs and Widgets design fundamentals for prerequisites, guidance and best practices.

Prerequisites for this release include:

- Developer mode enabled on the development machine.
- The development machine is running a version of Windows from the Dev Channel of the Windows Insider Program (WIP) with Widgets Board version 521.20060.1205.0 or above.

Known limitations when developing Widgets

- Third-party Widgets can only be tested locally on devices enrolled in WIP for this preview release. In Windows App SDK 1.2.0, users on retail versions of Windows can begin acquiring 3P Widgets via Microsoft Store shipped versions of your app.
- Widgets can only be created for packaged, Win32 apps. Widgets for Progressive Web Apps (PWA) are planned to be supported as part of Microsoft Edge 108.

Trimming for apps developed with .NET

.NET developers are now able to publish their WinAppSDK apps trimmed. With CsWinRT 2.0, the C#/WinRT projections distributed in WinAppSDK are now trimmable. Publishing your app trimmed can reduce the disk footprint of your app by removing any unused code from trimmable binaries. Apps may also see a startup performance improvement. With a basic Hello World app, we have seen a ~80% disk footprint improvement and a ~7% startup performance improvement when published trimmed. With WinUI gallery, we have seen a ~45% disk footprint improvement.

For more details on how to enable trimming, trimming limitations (such as reflection against trimmable types), and trim warnings, see Trim self-contained deployments and executables. Developers should thoroughly test their apps after trimming to ensure everything works as expected. For more information, check out issue 2478 on GitHub.

DisplayInformation

Win32 apps can now support High Dynamic Range (HDR) through the DisplayInformation class in WinAppSDK. The DisplayInformation class enables you to monitor display-related information for an application view. This includes events to allow clients to monitor for changes in the application view affecting which display(s) the view resides on, as well as changes in displays that can affect the application view.

Fixed issues in WinUI 3

- Acrylic backdrop material via DesktopAcrylicController is now supported in Windows 10 apps. For more information, check out issue 7112 on GitHub.
- Fixed issue causing App.UnhandledException to fail to be routed to the application. For more information, check out issue 5221 on GitHub.
- Fixed issue causing ListView styles to regress and change from WinAppSDK 1.1. For more information, check out issue 7666 on GitHub.

Other limitations and known issues (1.2.0-preview2)

> **Important**
>
> When you reference WinAppSDK 1.2 from a project you might see an error similar to: "*Detected package downgrade: Microsoft.Windows.SDK.BuildTools from 10.0.22621.1 to 10.0.22000.194.*", which is caused by incompatible references to the package from the app project and the WinAppSDK package. To resolve this you can

update the reference in the project to a more recent and compatible version of Microsoft.Windows.SDK.BuildTools, or simply remove the reference from your project. If you remove it from your project, a compatible version will be implicitly referenced by the WinAppSDK package.

- Building with Arm64 Visual Studio is not currently supported.
- Bootstrapper and Undocked RegFree WinRT auto-initializer defaults is (now) only set for projects that produce an executable (OutputType=Exe or WinExe). This prevents adding auto-initializers into class library DLLs and other non-executables by default.
  - If you need an auto-initializer in a non-executable (e.g. a test DLL loaded by a generic executable that doesn't initialize the Bootstrapper) you can explicitly enable an auto-initializer in your project via `<WindowsAppSdkBootstrapInitialize>true</WindowsAppSdkBootstrapInitialize>` or `<WindowsAppSdkUndockedRegFreeWinRTInitialize>true</WindowsAppSdkUndockedRegFreeWinRTInitialize>`.
- The version information APIs (ReleaseInfo and RuntimeInfo) can be called but return version 0 (not the actual version information).

Version 1.2 Preview 1 (1.2.0-preview1)

In an existing Windows App SDK 1.1 (from the stable channel) app, you can update your Nuget package to 1.2.0-preview1 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager).

For the updated runtime and MSIX, see Latest Windows App SDK downloads.

WinUI 3

WinUI 3 apps can play audio and video with the **MediaPlayerElement** and **MediaTransportControls** media playback controls. For more info on how and when to use media controls, see Media players.

WinUI 3 has been updated with the latest controls, styles, and behaviors from WinUI 2.8. These updates include the addition of the **InfoBadge** control, improvements to accessibility and high contrast mode, as well as bug fixes across controls. For more details, see the release notes for WinUI 2.7 and WinUI 2.8.

Known issue

ListView styles regressed and changed from WinAppSDK 1.1.

Notifications

AppNotificationBuilder introduced as an alternative to XML payload for creating and defining App Notifications.

For usage information, see the AppNotificationBuilder spec on GitHub.

Also see Quickstart: App notifications in the Windows App SDK for an example of how to create a desktop Windows application that sends and receives local app notifications.

Breaking change

For push notifications, when making a channel request call, apps will need to use the Azure Object ID instead of the Azure App ID. See Quickstart: Push notification in the Windows App SDK for details on finding your Azure Object ID.

Fixed issue

PushNotificationManager.IsSupported will perform a check for elevated mode. It will return `false` if the app is elevated.

Known limitations (Notifications)

- In **AppNotificationScenario**, `Urgent` is only supported for Windows builds 19041 and later. You can use **AppNotificationBuilder.IsUrgentScenarioSupported** to check whether the feature is available at runtime.
- In **AppNotificationButton**, `hint-toolTip` and `hint-buttonStyle` are only supported for builds 19041 and later. You can use **IsButtonStyleSupported** and **IsToolTipSupported** to check whether the feature is available at runtime.
- In **MediaPlayerElement**, when used in XAML markup for an unpackaged app, the **Source** property cannot be set with an ms-appx or ms-resource URI. As an alternative, set the Source using a file URI, or set from code.

Windowing

Full title bar customization is now available on Windows 10, version 1809 and later through the **AppWindowTitleBar** class. You can set **AppWindowTitleBar.ExtendsContentIntoTitleBar** to `true` to extend content into the

title bar area, and **SetDragRectangles** to define drag regions (in addition to other customization options).

If you've been using the **AppWindowTitleBar.IsCustomizationSupported** property to check whether you can call the **AppWindowTitleBar** APIs, it now returns `true` on supported Windows App SDK Windows 10 versions (1809 and later).

Known limitations (Windowing)

Simple title bar customizations are not supported on Windows 10. These include **BackgroundColor**, **InactiveBackgroundColor**, **ForegroundColor**, **InactiveForegroundColor** and **IconShowOptions**. If you call these properties, they will be ignored silently. All other **AppWindowTitleBar** APIs work in Windows 10, version 1809 and later. For the caption button color APIs (among others) and **Height**, **ExtendsContentIntoTitleBar** must be set to `true`, otherwise they will also be ignored silently.

Access control

Introduced security.accesscontrol.h with the **GetSecurityDescriptorForAppContainerNames** function to ease and streamline named object sharing between packaged processes and general Win32 APIs. This method takes a list of Package Family Names (PFNs) and access masks, and returns a security descriptor. For more information, see the GetSecurityDescriptorForAppContainerNames spec on GitHub.

Other limitations and known issues (1.2.0-preview1)

- .NET PublishSingleFile isn't supported.

Preview channel release notes for the Windows App SDK 1.1

Article • 05/23/2024

> **ⓘ Important**
>
> The preview channel is **not supported** for use in production environments, and apps that use the preview releases cannot be published to the Microsoft Store.

The preview channel includes releases of the Windows App SDK with preview channel features in late stages of development. Preview releases do not include experimental features and APIs but may still be subject to breaking changes before the next stable release.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on preview releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest preview channel release:

- Latest preview channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.1 Preview 3 (1.1.0-preview3)

This is the latest release of the preview channel for version 1.1. It supports all preview channel features (see Features available by release channel).

In an existing app using Windows App SDK 1.0, you can update your Nuget package to 1.1.0-preview3 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager). Additionally, see Latest Windows App SDK downloads for the updated runtime and MSIX.

> **Note**
>
> For C# developers, one of the following .NET SDK versions (or later) is required: 6.0.202, 6.0.104, 5.0.407, 5.0.213. To update your .NET SDK version, visit .NET Downloads or update to the latest version of Visual Studio. Without the required .NET SDK version, when updating your NuGet package you will see an error like: "*This version of WindowsAppSDK requires WinRT.Runtime.dll version 1.6 or greater.*".

In addition to all of the Preview 2 features, the following sections describe new and updated features, limitations, and known issues for this release.

WinUI 3 (1.1.0-preview3)

Mica and Background Acrylic are now available for WinUI 3 applications.

For more information about these materials, check out Materials in Windows 11. Check out our sample code for applying Mica in C++ applications at Apply Mica or Acrylic materials in desktop apps for Windows 11 and in C# applications on GitHub as part of the WinUI Controls Gallery.

Notifications (1.1.0-preview3)

Fixed issues:

- In 1.1.0-preview1 and 1.1.0-preview2, some unpackaged apps will have seen their app icons incorrectly copied to AppData\LocalMicrosoftWindowsAppSDK. For this release, they will be copied to AppData\Local\Microsoft\WindowsAppSDK instead. To avoid leaking icons, you should manually delete the app icon at the incorrect path after updating to 1.1.0-preview3.
- App icon and app display name retrieval for app notifications via Shortcuts is now supported. This app icon will be prioritized over any icon specified in resource files.
- Support for push notifications for unpackaged apps has been restored (see **Limitations** for noted exception). We've introduced the PushNotificationManager::IsSupported API to check if your app supports push notifications.

Limitations:

- Notifications for an *elevated* unpackaged app is not supported. PushNotificationManager::IsSupported will not perform a check for elevated mode. However, we are working on supporting this in a future release.

MSIX packaging

We've enhanced MSIX adding new and extending existing functionality via the extension categories:

- windows.appExecutionAlias
- windows.customDesktopEventLog
- windows.dataShortcuts
- windows.fileTypeAssociation
- windows.fileTypeAssociation.iconHandler
- windows.folder
- windows.shortcut

These require the Windows App SDK framework package to be installed. See Latest Windows App SDK downloads to install the runtime.

Environment manager (1.1.0-preview3)

API set that allows developers to add, remove, and modify environment variables without having to directly use the registry API.

Clarification from 1.1 Preview 1: Automatic removal of any environment variable changes when an app that used environment manager is uninstalled is only available for packaged apps. Additionally, reverting environment variable changes requires installation of the Windows App SDK framework package, see Latest Windows App SDK downloads for the runtime.

Other known limitations

Regressions from 1.1 Preview 2:

- For .NET apps using MRT Core APIs and WinUI apps that *don't* deploy with single-project MSIX:
  - RESW and image files that were added to the project as Existing Items and previously automatically included to the PRIResource and Content ItemGroups, respectively, won't be included in those ItemGroups. As a result, these resources won't be indexed during PRI generation, so they won't be available during runtime.
    - Workaround: Manually include the resources in the project file and remove them from the None ItemGroup.
    - Alternative workaround: When available, upgrade your apps' .NET SDK to 6.0.300. See Version requirements for .NET SDK for additional information.

- For .NET apps that *don't* deploy with single-project MSIX:
  - If a file is added to the Content ItemGroup twice or more, then there will be a build error.
    - Workaround: Delete the duplicate inclusion/s or set EnableDefaultContentItems to false in the project file.

Both regressions will be restored in the next stable release.

Version 1.1 Preview 2 (1.1.0-preview2)

This is the second release of the preview channel for version 1.1. It supports all preview channel features (see Features available by release channel).

In an existing app using Windows App SDK 1.0, you can update your Nuget package to 1.1.0-preview2 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager). Additionally, see Latest Windows App SDK downloads for the updated runtime and MSIX.

> **Note**
>
> For C# developers, one of the following .NET SDK versions (or later) is required: 6.0.202, 6.0.104, 5.0.407, 5.0.213. To update your .NET SDK version, visit .NET Downloads or update to the latest version of Visual Studio. Without the required .NET SDK version, when updating your NuGet package you will see an error like: "*This version of WindowsAppSDK requires WinRT.Runtime.dll version 1.6 or greater.*".

In addition to all of the Preview 1 features, the following sections describe new and updated features, limitations, and known issues for this release.

Notifications (1.1.0-preview2)

Fixed issues:

- An app without package identity sending notifications will now see its app icon in the notification if the icon is a part of the app's resource. If the app resource has no icon, the Windows default app icon is used.
- A WinUI 3 app that's not running can now be background-activated via a notification.

Regression from 1.1 Preview 1: Push notifications support for unpackaged apps. Expected to be restored in the next release.

Known limitations:

- We've introduced the PushNotificationManager::IsSupported API to check if self-contained apps support push notifications. However, this API is not yet working as intended, so keep an eye out in the next preview release for full support of the IsSupported API.
- Some unpackaged apps will see their app icons incorrectly copied to AppData\LocalMicrosoftWindowsAppSDK. For the next release, they will be copied to AppData\Local\Microsoft\WindowsAppSDK instead. To avoid leaking icons, the developer should manually delete their app icon at the incorrect path after upgrading to the next release.
- App icon and app display name retrieval for notifications via Shortcuts is not supported. But we're working on supporting that in a future release.

Deployment

New features:

- Packaged apps can now force deploy the Windows App SDK runtime packages using the **DeploymentManager.Initialize** API.
- The Bootstrapper API now includes new options for improved usability and troubleshooting. For more details, see Use the Windows App SDK runtime for apps packaged with external location or unpackaged and Rich information on Bootstrap initialization failure.

Known limitations:

- Self-contained deployment is supported only on Windows 10, 1903 and later.

Windowing

For easier programming access to functionality that's implemented in `USER32.dll` (see Windows and messages), this release surfaces more of that functionality in **AppWindow** itself.

New features:

- Apps with existing windows have more control over how a window is shown, by calling **AppWindow.ShowOnceWithRequestedStartupState**—the equivalent of `ShowWindow(SW_SHOWDEFAULT)`.
- Apps can show, minimize, or restore a window and specify whether the window should be activated or not at the time the call is made.

- Apps can now set a window's client area size in Win32 coordinates.
- We've added APIs to support z-order management of windows.
- Apps drawing custom titlebars with **AppWindowTitleBar.ExtendsContentIntoTitleBar** can set a *PreferredTitleBarHeight* option. You have a choice of a *standard height* titlebar, or a *tall* titlebar that provides more room for interactive content. See Title bar in the Fluent design guidelines for advice about when to use a tall titlebar.

Known limitations:

- Tall titlebar support is available only on Windows 11. We are working to bring this downlevel along with other custom titlebar APIs.

WinUI 3 (1.1.0-preview2)

Fixed issues:

- Fixed issue causing C# apps with WebView2 to crash on launch when the C/C++ Runtime (CRT) isn't installed by upgrading the WebView2 SDK from 1020.46 to 1185.39.
- Fixed issue causing some rounded corners to show a gradient when they should be a solid color. For more information see issue 6076 & issue 6194 on GitHub.
- Fixed issue where updated styles were missing from generic.xaml.
- Fixed layout cycle issue causing an app to crash when scrolling to the end of a ListView. For more information see issue 6218 on GitHub.

Performance

C# applications have several performance improvements. For more details, see the C#/WinRT 1.6.1 release notes.

Version 1.1 Preview 1 (1.1.0-preview1)

This is the first release of the preview channel for version 1.1. It supports all preview channel features (see Features available by release channel).

In an existing app using Windows App SDK 1.0, you can update your Nuget package to 1.1.0-preview1 (see the **Update a package** section in Install and manage packages in Visual Studio using the NuGet Package Manager). Additionally, see Latest Windows App SDK downloads for the updated runtime and MSIX.

The following sections describe new and updated features, limitations, and known issues for this release.

WinUI 3 (1.1.0-preview1)

Known issue: Users are unable to drop an element when drag-and-drop is enabled.

Elevated (admin) support

Using Windows App SDK 1.1 Preview 1, apps (including WinUI 3) will be able to run with elevated privilege.

Important limitations:

- Currently available only on Windows 11. But we're evaluating bringing this support downlevel in a later release.

Known issues:

- WinUI 3 apps crash when dragging an element during a drag-and-drop interaction.

Self-contained deployment

Windows App SDK 1.1 will introduce support for self-contained deployment. Our Windows App SDK deployment overview details the differences between framework-dependent and self-contained deployment, and how to get started.

Known issues:

- A C++ app that's packaged needs to add the below to the bottom of its project file to work around a bug in the self-contained `.targets` file that removes framework references to VCLibs:

```
XML
<PropertyGroup>

<IncludeGetResolvedSDKReferences>true</IncludeGetResolvedSDKReferences>
</PropertyGroup>

<Target Name="_RemoveFrameworkReferences"

BeforeTargets="_ConvertItems;_CalculateInputsForGenerateCurrentProjectA
ppxManifest">
```

```
    <ItemGroup>
        <FrameworkSdkReference Remove="@(FrameworkSdkReference)"
Condition="'%(FrameworkSdkReference.SDKName)' ==
'Microsoft.WindowsAppRuntime.1.1-preview1'" />
    </ItemGroup>
</Target>
```

- Supported only on Windows 10, 1903 and later.

Notifications (1.1.0-preview1)

Developers of packaged (including packaged with external location) and unpackaged apps can now send Windows notifications.

New features:

- Support for app notifications for packaged and unpackaged apps. Full details on GitHub
  - Developers can send app notifications, also known as toast notifications, locally or from their own cloud service.
- Support for push notification for packaged and unpackaged apps. Full details on GitHub
  - Developers can send raw notifications or app notifications from their own cloud service.

Limitations:

- Apps published as self-contained may not have push notifications support. Keep an eye out in the next preview release for an **IsSupported** API to check for push notifications support.
- Apps that are unpackaged sending app notifications will not see their app icon in the app notification unless they are console applications. Console apps that are unpackaged should follow the patterns shown in the ToastNotificationsDemoApp sample.
- Windows App SDK runtime must be installed to support push notifications, see Latest Windows App SDK downloads for the installer.
- A WinUI 3 app that's not running can't be background-activated via a notification. But we're working on supporting that in a future release.

Environment manager (1.1.0-preview1)

API set that allows developers to add, remove, and modify environment variables without having to directly use the registry API.

New features:

- Provides automatic removal of any environment variables changes when an app that used environment manager is uninstalled.

Limitations:

- Currently unavailable in C# apps. But we're evaluating bringing this feature to C# apps in a later release.

Other limitations and known issues

- If you're using C# with 1.1.0 Preview 1, then you must use one of the following .NET SDK versions at a minimum: .NET SDK 6.0.201, 6.0.103, 5.0.212, or 5.0.406. To upgrade your .NET SDK, you can update to the latest version of Visual Studio, or visit Download .NET.

Preview channel release notes for the Windows App SDK 1.0

Article • 05/23/2024

> **Important**
>
> The preview channel is **not supported** for use in production environments, and apps that use the preview releases cannot be published to the Microsoft Store.

The preview channel includes releases of the Windows App SDK with preview channel features in late stages of development. Preview releases do not include experimental features and APIs but may still be subject to breaking changes before the next stable release.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on preview releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest preview channel release:

- Latest preview channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.0 Preview 3 (1.0.0-preview3)

Preview 3 is the latest release of the preview channel for version 1.0 of the Windows App SDK. Preview 3 supports all preview channel features.

Download 1.0 Preview 3 Visual Studio extensions (VSIX)

> **Note**

If you have Windows App SDK Visual Studio extensions (VSIX) already installed, then uninstall them before installing a new version. For directions, see Manage extensions for Visual Studio.

From the table below you can download the Visual Studio extensions (VSIX) for the 1.0 Preview 3 release. For all versions, see Latest Windows App SDK downloads. If you haven't done so already, start by configuring your development environment, using the steps in Install tools for the Windows App SDK.

The extensions below are tailored for your programming language and version of Visual Studio.

Expand table

1.0 Preview 3 downloads	Description
C# Visual Studio 2019 extension	Build C# apps with the Windows App SDK Visual Studio 2019 extension.
C++ Visual Studio 2019 extension	Build C++ apps with the Windows App SDK Visual Studio 2019 extension.
C# Visual Studio 2022 extension	Build C# apps with the Windows App SDK Visual Studio 2022 extension.
C++ Visual Studio 2022 extension	Build C++ apps with the Windows App SDK Visual Studio 2022 extension.
The .exe installer, and MSIX packages	Deploy the Windows App SDK with your app using the `.exe` installer, and MSIX packages.

The following sections describe new and updated features, limitations, and known issues for 1.0 Preview 3.

WinUI 3 (1.0.0-preview3)

We now support deploying WinUI 3 apps without MSIX packaging. See Create your first WinUI 3 (Windows App SDK) project to configure your WinUI 3 application to support unpackaged deployment.

Important limitations:

- Unpackaged WinUI 3 applications are **supported only on Windows versions 1909 and later**.

- Unpackaged WinUI 3 applications are **supported on x86 and x64**; arm64 support will be added in the next stable release.
- **Single-project MSIX Packaging Tools** for Visual Studio 2019 or Visual Studio 2022 is required for unpackaged apps.
- In an unpackaged app, you might receive a prompt to install .NET 3.5; if you do, then you can ignore it.
- Some APIs are not currently supported in unpackaged apps. We're aiming to fix this in the next stable release. A few examples:
  - ApplicationData
  - StorageFile.GetFileFromApplicationUriAsync
  - ApiInformation (not supported on Windows 10)
  - Package.Current
- ListView, CalendarView, and GridView controls are using the incorrect styles, and we're aiming to fix this in the next stable release.

For more info, or to get started developing with WinUI 3, see:

- WinUI
- Create your first WinUI 3 (Windows App SDK) project

Other limitations and known issues:

- **Unpackaged apps are not supported on Windows 10 version 1809**. We're aiming to fix this in the next release in the stable channel.

- **C# Single-project MSIX app doesn't compile if C++ UWP Tools aren't installed**. If you have a C# Single-project MSIX project, then you'll need to install the **C++ (v14x) Universal Windows Platform Tools** optional component.

- This release introduces the **Blank App, Packaged (WinUI 3 in Desktop)** project templates for C# and C++. These templates enable you to build your app into an MSIX package without the use of a separate packaging project (see Package your app using single-project MSIX). These templates have some known issues in this release:

  - **Missing Publish menu item until you restart Visual Studio**. When creating a new app in both Visual Studio 2019 and Visual Studio 2022 using the **Blank App, Packaged (WinUI 3 in Desktop)** project template, the command to publish the project doesn't appear in the menu until you close and re-open Visual Studio.

  - **Error when adding C++ static/dynamic library project references to C++ apps using Single-project MSIX Packaging**. Visual Studio displays an error that the

project can't be added as a reference because the project types are not compatible.

  - **Error when referencing a custom user control in a class library project**. The application will crash with the error that the system can't find the path specified.

  - **C# or C++ template for Visual Studio 2019**. When you try to build the project, you'll encounter the error "The project doesn't know how to run the profile *project name*". To resolve this issue, install the Single-project MSIX Packaging Tools extension.

  - **C# template for Visual Studio 2019 and Visual Studio 2022**. In Visual Studio when you **Start Debugging** or **Start Without Debugging**, if your app doesn't deploy and run (and there's no feedback from Visual Studio), then click on the project node in **Solution Explorer** to select it, and try again.

  - **C# template for Visual Studio 2019 and Visual Studio 2022**. You will encounter the following error when you try to run or debug your project on your development computer: "The project needs to be deployed before we can debug. Please enable Deploy in the Configuration Manager." To resolve this issue, enable deployment for your project in **Configuration Manager**. For detailed instructions, see the Create your first WinUI 3 (Windows App SDK) project.

  - **C++ template for Visual Studio 2022 version 17.0 releases up to Preview 4**. You will encounter the following error the first time you try to run your project: "There were deployment errors". To resolve this issue, run or deploy your project a second time. This issue will be fixed in Visual Studio 2022 version 17.0 Preview 7.

- **No support for Any CPU build configuration**: When adding the Windows App SDK to an existing .NET application or component that supports **Any CPU**, you must specify the desired architecture: `x86`, `x64` or `arm64`.

- **C# projects using 1.0 Preview 3 must use the following .NET SDK**: .NET 6 SDK or later (see Download .NET and .NET 5 will reach End of Support on May 10, 2022).

- An alternative to **DispatcherQueue.TryEnqueue** (for resuming execution on the dispatcher queue thread) is to use the resume_foreground helper function in the Windows Implementation Library (WIL):

  1. Add a reference to your project to the Microsoft.Windows.ImplementationLibrary NuGet package.

2. Add `#include <wil/cppwinrt_helpers.h>` to your `pch.h`.
3. Add `#include <winrt/Microsoft.UI.Dispatching.h>` to your `pch.h`.
4. Now `co_await wil::resume_foreground(your_dispatcherqueue);`.

Important issue impacting 1.0 Preview 1 and Preview 2

Version 1.0 Preview 1 and Preview 2 of the Windows App SDK includes a mechanism to clean up any environment variable changes made by a packaged app when that app is uninstalled. This feature is in an experimental state, and the first release includes a known bug that can corrupt the system **PATH** environment variable.

Preview 1 and Preview 2 corrupts any **PATH** environment variable that contains the expansion character `%`. This happens whenever any packaged app is uninstalled, regardless of whether that app uses the Windows App SDK.

Also see PATH environment variable corruption issue.

Details

The system **PATH** entry is stored in the **Path** value in the following key in the Windows Registry:

`Computer\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Environment`

If you launch the Registry Editor (`regedit.exe`), then you can copy and paste the path above into the breadcrumb bar (immediately below the menu bar), and press Enter to locate the key.

The **Path** value of that key *should* be of type **REG_EXPAND_SZ**, but the bug changes it to **REG_SZ**. And that makes the system **PATH** environment variable unusable if it contains the variable expansion character `%`.

Affected releases

- Windows App SDK 1.0 Preview 1 (1.0.0-preview1)
- Windows App SDK 1.0 Preview 2 (1.0.0-preview2)

Mitigation

To get your machine back into a good state, take the following steps:

1. Check whether the **PATH** in the Registry is corrupt and, if so, reset it by running the script below.

   You can accomplish step 1 with the following Windows PowerShell script (PowerShell Core won't work). Run it elevated.

   Powershell

   ```
   # This script must be run from an elevated Windows PowerShell
   # window (right-click Windows PowerShell in the Start menu,
   # and select Run as Administrator).

   # If the PATH in the Registry has been set to REG_SZ, then delete
   # it, and recreate it as REG_EXPAND_SZ.

   $EnvPath = 'Registry::HKLM\System\CurrentControlSet\Control\Session
   Manager\Environment'
   $Environment=Get-Item $EnvPath
   $PathKind = $Environment.GetValueKind('Path')

   if ($PathKind -ne 'ExpandString') {
     $Path = $Environment.GetValue('Path')
     Remove-ItemProperty $EnvPath -Name Path
     New-ItemProperty $EnvPath -Name Path -PropertyType ExpandString -
   Value $Path
   }
   ```

2. Uninstall all apps that use the Windows App SDK 1.0 Preview1 or Preview2 (see the script below).

3. Uninstall the Windows App SDK 1.0 Preview1/Preview2 packages, including the package that contains the bug (see the script below).

   You can accomplish steps 2 and 3 with the following Windows PowerShell script (PowerShell Core won't work). Run it elevated.

   Powershell

   ```
   # This script must be run from an elevated Windows PowerShell
   # window (right-click Windows PowerShell in the Start menu,
   # and select Run as Administrator).

   # Remove the Windows App SDK 1.0 Preview1/2, and all apps that use it.

   $winappsdk = "Microsoft.WindowsAppRuntime.1.0-preview*"
   Get-AppxPackage | Where-Object { $_.Dependencies -like $winappsdk } |
   ```

```
Remove-AppxPackage
Get-AppxPackage $winappsdk | Remove-AppxPackage
```

Fix in Windows App SDK 1.0 Preview 3

The feature causing the **PATH** environment variable to be corrupted will be removed in the upcoming Windows App SDK 1.0 Preview 3 release. It might be reintroduced at a later date, when all bugs have been fixed and thoroughly tested.

We recommend using version 1.0 Preview 3.

Version 1.0 Preview 2 (1.0.0-preview2)

> **ⓘ Important**
>
> Version 1.0 Preview 1 and Preview 2 contain a critical bug. If you've already installed one of these previews, see **how to resolve the issue**. We recommend using version **1.0 Preview 3** instead.

This is the latest release of the preview channel for version 1.0. It supports all preview channel features.

The following sections describe new and updated features, limitations, and known issues for this release.

WinUI 3 (1.0.0-preview2)

New updates:

- Controls have been updated to reflect the latest Windows styles from WinUI 2.6.
- Single-project MSIX is supported.
- WinUI 3 package can now target build 17763 and later. See issue #921 for more info.
- In-app toolbar is supported. However, the in-app toolbar and existing Hot Reload/Live Visual Tree support require the upcoming Visual Studio 17.0 Preview 5 release, available later in October.

Bug fixed: WebView2Runtime text is now localized.

For more info or to get started developing with WinUI 3, see:

- WinUI

- Create your first WinUI 3 (Windows App SDK) project

Windowing (1.0.0-preview2)

This release introduces updates to the AppWindow class. There are no major new features added in this release, but there are changes to method names, properties, and some return values have been removed. See the documentation and samples for detailed updates. If you worked with AppWindow in the 1.0 Experimental or 1.0 Preview 1 releases, expect some changes to your code.

New updates:

- The **AppWindowConfiguration** class has been removed. The properties of this class is now available on the AppWindow itself, or on the **Presenter** classes.
- Most `bool` return values for the WinRT API methods in this space has been removed and are now `void` since these methods would always succeed.
- The C# ImportDll calls are no longer needed for GetWindowIdFromWindow and GetWindowFromWindowId. Use the .NET wrapper methods available in the **Microsoft.UI.Win32Interop** class instead.

Important limitations:

- The Windows App SDK does not currently provide methods for attaching UI framework content to an AppWindow; you're limited to using the HWND interop access methods.
- Window title bar customization works only on Windows 11. Use the IsCustomizationSupported method to check for title bar customization feature support. We intend to bring this functionality down-level.

For more info, see Manage app windows (Windows App SDK).

Input (1.0.0-preview2)

New updates:

- Improved support for precision touchpad input.

Important limitations:

- All PointerPoint static factory functions have been removed: **GetCurrentPoint**, **GetCurrentPointTransformed**, **GetIntermediatePoints**, and **GetIntermediatePointsTransformed**.

- The Windows App SDK does not support retrieving **PointerPoint** objects with pointer IDs. Instead, you can use the **PointerPoint** member function **GetTransformedPoint** to retrieve a transformed version of an existing **PointerPoint** object. For intermediate points, you can use the **PointerEventArgs** member functions GetIntermediatePoints and **GetTransformedIntermediatePoints**. See the documentation for additional details.

MRT Core (1.0.0-preview2)

New updates:

- App developers can now opt out an image file or a RESW file from being indexed in the PRI file in .NET projects. See issue 980 for more info.

Important limitations:

- In .NET projects, resource files copy-pasted into the project folder aren't indexed on F5 if the app was already built. As a workaround, rebuild the app. See issue 1503 for more info].
- In .NET projects, existing resource files added from an external folder aren't indexed without manual setting of the Build Action. To work around this issue, set the Build Action in Visual Studio: **Content** for image files and **PRIResource** for RESW files. See issue 1504 for more info.

Deployment for unpackaged apps

New features:

- Windows App SDK 1.0 Preview 2 introduces a .NET wrapper for the bootstrapper API (see Use the Windows App SDK runtime for apps packaged with external location or unpackaged). The bootstrapper API is a set of native C/C++ functions that unpackaged apps must use to dynamically take a dependency on the Windows App SDK framework package at run time. The .NET wrapper provides an easier way to call the bootstrapper API from .NET apps, including Windows Forms and WPF apps. The .NET wrapper for the bootstrapper API is available in the Microsoft.WindowsAppRuntime.Bootstrap.Net.dll assembly, which is local to your app project. For more info about the .NET wrapper, see .NET wrapper library.
- Packaged apps can now use the deployment API to get the main and singleton MSIX packages installed on the machine. The main and singleton packages are part of the framework package that is installed with the app, but due to a limitation with the Windows application model, packaged apps will need to take this additional step in order to get those packages installed. For more info about

how the deployment API works, see Windows App SDK deployment guide for framework-dependent packaged apps.

Important limitations:

- The .NET wrapper for the bootstrapper API only is only intended for use by unpackaged .NET applications to simplify access to the Windows App SDK.
- Only MSIX packaged apps that are full trust or have the packageManagement restricted capability have the permission to use the deployment API to install the main and singleton package dependencies. Support for partial-trust packaged apps will be coming in later releases.
- When F5 testing an x86 app which uses the DeploymentManager.Initialize method on an x64 system, ensure that the x64 framework is first installed by running the WindowsAppRuntimeInstall.exe. Otherwise, you will encounter a **NOT_FOUND** error due to Visual Studio not deploying the x64 framework, which normally occurs through Store deployment or sideloading.

App lifecycle

Most of the App Lifecycle features already exist in the UWP platform, and have been brought into the Windows App SDK for use by desktop app types, especially unpackaged Console apps, Win32 apps, Windows Forms apps, and WPF apps. The Windows App SDK implementation of these features cannot be used in UWP apps, since there are equivalent features in the UWP platform itself.

Non-UWP apps can also be packaged into MSIX packages. While these apps can use some of the Windows App SDK App Lifecycle features, they must use the manifest approach where this is available. For example, they cannot use the Windows App SDK **RegisterForXXXActivation** APIs and must instead register for rich activation via the manifest.

All the constraints for packaged apps also apply to WinUI 3 apps that are packaged; and there are additional considerations as described below.

Important considerations:

- Rich activation: GetActivatedEventArgs
  - *Unpackaged apps*: Fully usable.
  - *Packaged apps*: Usable, but these apps can also use the platform `GetActivatedEventArgs`. Note that the platform defines Windows.ApplicationModel.AppInstance whereas the Windows App SDK defines Microsoft.Windows.AppLifecycle.AppInstance. And while UWP apps can use the `ActivatedEventArgs` classes, such as `FileActivatedEventArgs` and

`LaunchActivatedEventArgs`, apps that use the Windows App SDK AppLifecycle feature must use the interfaces not the classes (e.g, `IFileActivatedEventArgs`, `ILaunchActivatedEventArgs`, and so on).
    - *WinUI 3 apps*: WinUI 3's App.OnLaunched is given a Microsoft.UI.Xaml.LaunchActivatedEventArgs, whereas the platform `GetActivatedEventArgs` returns a Windows.ApplicationModel.IActivatedEventArgs, and the WindowsAppSDK `GetActivatedEventArgs` returns a Microsoft.Windows.AppLifecycle.AppActivationArguments object which can represent a platform `LaunchActivatedEventArgs`.
    - For more info, see Rich activation with the app lifecycle API.

- Register/Unregister for rich activation
    - *Unpackaged apps*: Fully usable.
    - *Packaged apps*: Not usable use the app's MSIX manifest instead.
    - For more info, see Rich activation with the app lifecycle API.

- Single/Multi-instancing
    - *Unpackaged apps*: Fully usable.
    - *Packaged apps*: Fully usable.
    - *WinUI 3 apps*: If an app wants to detect other instances and redirect an activation, it must do so as early as possible, and before initializing any windows, etc. To enable this, the app must define DISABLE_XAML_GENERATED_MAIN, and write a custom Main (C#) or WinMain (C++) where it can do the detection and redirection.
    - RedirectActivationToAsync is an async call, and you should not wait on an async call if your app is running in an STA. For Windows Forms and C# WinUI 3 apps, you can declare Main to be async, if necessary. For C++ WinUI 3 and C# WPF apps, you cannot declare Main to be async, so instead you need to move the redirect call to another thread to ensure you don't block the STA.
    - For more info, see App instancing with the app lifecycle API.

- Power/State notifications
    - *Unpackaged apps*: Fully usable.
    - *Packaged apps*: Fully usable.
    - For more info, see Power management with the app lifecycle API.

Known issue:

File Type associations incorrectly encode %1 to be %251 when setting the Verb handler's command line template, which crashes unpackaged Win32 apps. You can manually edit

the Registry value to be %1 instead as a partial workaround. If the target file path has a space in it, then it will still fail and there is no workaround for that scenario.

Other limitations and known issues:

- Version 1.0 Preview 1 and Preview 2 contain a critical bug. If you've already installed one of these previews, see how to resolve the issue. We recommend using version 1.0 Preview 3 instead.
- This release introduces the **Blank App, Packaged (WinUI 3 in Desktop)** templates for C# and C++ projects. These templates enable you to build your app into an MSIX package without the use of a separate packaging project. These templates have some known issues in this release:
  - **C# template for Visual Studio 2019.** You will encounter the error when you try to build the project: "The project doesn't know how to run the profile *project name*". To resolve this issue, install the Single-project MSIX Packaging Tools extension.
  - **C# template for Visual Studio 2019 and Visual Studio 2022.** You will encounter the following error when you try to run or debug your project on your development computer: "The project needs to be deployed before we can debug. Please enable Deploy in the Configuration Manager." To resolve this issue, enable deployment for your project in **Configuration Manager**. For detailed instructions, see the Create your first WinUI 3 (Windows App SDK) project.
  - **C++ template for Visual Studio 2019 and Visual Studio 2022.** In this release, these projects are restricted to calling the subset of Win32 APIs that can be called by UWP apps. The **Blank App, Packaged with WAP (WinUI 3 in Desktop)** template is not affected by this issue.
  - **C++ template for Visual Studio 2022 version 17.0 releases up to Preview 4.** You will encounter the following error the first time you try to run your project: "There were deployment errors". To resolve this issue, run or deploy your project a second time. This issue will be fixed in Visual Studio 2022 version 17.0 Preview 5.
- **Push notifications API (Microsoft.Windows.PushNotifications namespace) incorrectly included in the 1.0 Preview 2 release.** This is still an experimental feature, and to you use it you must install the 1.0 Experimental release instead. This feature will be removed from the upcoming 1.0 release.

- **App lifecycle API (Microsoft.Windows.AppLifecycle namespace) incorrectly includes the Experimental attribute in the 1.0 Preview 2 release.** The Experimental attribute will be removed from this API in the next release.
- **No support for Any CPU build configuration**: When adding the Windows App SDK to an existing .NET application or component that supports **Any CPU**, you must specify the desired architecture: `x86`, `x64` or `arm64`.
- **C# projects using 1.0 Preview 2 must use the following .NET SDK**: .NET 6 SDK or later (see Download .NET and .NET 5 will reach End of Support on May 10, 2022).
- An alternative to **DispatcherQueue.TryEnqueue** (for resuming execution on the dispatcher queue thread) is to use the resume_foreground helper function in the Windows Implementation Library (WIL):

    1. Add a reference to your project to the Microsoft.Windows.ImplementationLibrary NuGet package.
    2. Add `#include <wil/cppwinrt_helpers.h>` to your `pch.h`.
    3. Add `#include <winrt/Microsoft.UI.Dispatching.h>` to your `pch.h`.
    4. Now `co_await wil::resume_foreground(your_dispatcherqueue);`.

Version 1.0 Preview 1 (1.0.0-preview1)

> **Important**
>
> Version 1.0 Preview 1 and Preview 2 contain a critical bug. If you've already installed one of these previews, see **how to resolve the issue**. We recommend using version **1.0 Preview 3** instead.

This is the first release of the preview channel for version 1.0. It supports all preview channel features.

The following sections describe new and updated features, limitations, and known issues for this release.

WinUI 3 (1.0.0-preview1)

This release of WinUI 3 is focused on building towards 1.0 with bug fixes.

- **New features**: No new features in Preview 1.

- **Fixed issues**: For the full list of issues addressed in this release, see our GitHub repo.

For more info or to get started developing with WinUI 3, see:

- WinUI
- Create your first WinUI 3 (Windows App SDK) project

Windowing (1.0.0-preview1)

This release brings the Windowing API we introduced in Experimental 1 to a Preview state. There are no major new features areas in this release as it is focused on bugfixes, stability, and adjustments to the API signature. The noteworthy changes and additions are called out below.

New features:

- DisplayAreaWatcher has been added to the Windowing APIs. This allows a developer to observe changes in the display topology and enumerate DisplayAreas currently defined in the system.
- AppWindow now supports setting the window icon via the SetIcon method, and AppWindowTitleBar now supports selecting whether to show/hide the window icon along with the system menu via the IconShowOptions property.

Important limitations:

- This release of AppWindow is currently available only to Win32 apps (both packaged and unpackaged).
- The Windows App SDK does not currently provide methods for attaching UI framework content to an AppWindow; you're limited to using the HWND interop access methods.
- Window title bar customization works only on Windows 11. Use the IsCustomizationSupported method to check for title bar customization feature support. We intend to bring this functionality down-level.

For more info, see Manage app windows (Windows App SDK).

Input (1.0.0-preview1)

This release brings some new features to the Input API. The noteworthy changes and additions are called out below.

New features and updates:

- PointerPredictor gives input latency sensitive applications such inking applications the ability to predict input point locations up to 15ms in the future to achieve better latency and smooth animation.
- PenDeviceInterop enables you to acquire a reference to the Windows.Devices.Input.PenDevice by using the FromPointerPoint method.
- InputCursor provides an explicit distinction between preset system cursor types and custom cursor types by removing the "Custom" type present in `CoreCursor`, and splitting the `CoreCursor` object into separate objects.
- Updates to InputCursor APIs.
- GestureRecognizer moved out of experimental to Microsoft.UI.Input.
- PointerPoint moved out of experimental to Microsoft.UI.Input.
- Mouse, touch, and pen input fully supported for WinUI 3 drag and drop.

Important limitations:

- This release of Input APIs has known issues with Windows version 1809.
- MRT Core is not yet supported by any subtype of InputCursor.
- Direct use of the platform SDK API Windows.UI.Core.CoreDragOperation will not work with WinUI 3 applications.
- PointerPoint properties RawPosition and ContactRectRaw were removed because they referred to non-predicted values, which were the same as the normal values in the OS. Use Position and ContactRect instead. Pointer prediction is now handled with the Microsoft.UI.Input.PointerPredictor API object.

MRT Core (1.0.0-preview1)

Starting in version 1.0 Preview 1, MRT Core APIs have moved from the Microsoft.ApplicationModel.Resources namespace to the Microsoft.Windows.ApplicationModel.Resources namespace.

Other limitations and known issues:

- Version 1.0 Preview 1 and Preview 2 contain a critical bug. If you've already installed one of these previews, see how to resolve the issue. We recommend using version 1.0 Preview 3 instead.

- Projects created by using the C++ **Blank App, Packaged with WAP (WinUI 3 in Desktop)** project template encounter the following build error by default: `fatal error C1083: Cannot open include file: 'winrt/microsoft.ui.dispatching.co_await.h': No such file or directory`. To resolve this issue, remove the following line of code from the **pch.h** file. This issue will be fixed in the next release.

```
C++

#include <winrt/microsoft.ui.dispatching.co_await.h>
```

- An alternative to **DispatcherQueue.TryEnqueue** (for resuming execution on the dispatcher queue thread) is to use the resume_foreground helper function in the Windows Implementation Library (WIL):

    1. Add a reference to your project to the Microsoft.Windows.ImplementationLibrary NuGet package.
    2. Add `#include <wil/cppwinrt_helpers.h>` to your `pch.h`.
    3. Add `#include <winrt/Microsoft.UI.Dispatching.h>` to your `pch.h`.
    4. Now `co_await wil::resume_foreground(your_dispatcherqueue);`.

- **No support for Any CPU build configuration**: The Windows App SDK is written in native code and thus does not support **Any CPU** build configurations. The WinUI 3 templates in Visual Studio only allow architecture-specific builds. When adding the Windows App SDK to an existing .NET application or component that supports **Any CPU**, you must specify the desired architecture: `x86`, `x64` or `arm64`.

- **.NET apps must target build 18362 or later**: Your TFM must be set to `net6.0-windows10.0.18362` or later, and your packaging project's `<TargetPlatformVersion>` must be set to 18362 or later. For more info, see the known issue on GitHub.

- **C# projects using 1.0 Preview 1 must use the following .NET SDK**: .NET 6 SDK or later (see Download .NET and .NET 5 will reach End of Support on May 10, 2022).

- **Unpackaged apps not supported on Windows 10 version 1809**: This should be resolved in the next release.

Experimental channel release notes for the Windows App SDK 1.7

Article • 04/16/2025

> **ⓘ Important**
>
> The experimental channel is **not supported** for use in production environments, and apps that use the experimental releases cannot be published to the Microsoft Store.

The experimental channel includes releases of the Windows App SDK with experimental channel features in early stages of development. APIs for experimental features have the Experimental attribute. If you call an experimental API in your code, you will receive a build-time warning. All APIs in the experimental channel are subject to extensive revisions and breaking changes. Experimental features and APIs may be removed from subsequent releases at any time.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on experimental releases, see Install tools for preview and experimental channels of the Windows App SDK.

Version 1.7 Experimental (1.7.0-experimental3)

Use on-device AI with Windows Copilot Runtime APIs

> **ⓘ Important**
>
> The underlying ML models required for these APIs currently require your device to be running the latest Windows 11 Insider Preview Build on the Dev Channel. Additionally,

these APIs require your device to be a Copilot+ PC. See **Copilot+ PCs Developer Guide** to learn more about these devices. APIs will throw an exception when called on devices lacking the necessary support.

The Windows Copilot Runtime (WCR) offers several AI-powered features and APIs for you to easily, efficiently, and responsibly use on-device AI models in your Windows apps. In this release we are making available several scenario focused APIs for you to leverage powerful capabilities without the need to find, run, or optimize your own Machine Learning (ML) models.

Learn more about responsible development practices used during WCR API development that you can also apply as you create AI-assisted features in the Developing Responsible Generative AI Applications and Features on Windows guidance.

Phi Silica

With **Phi Silica**, Microsoft's most powerful NPU-tuned local language model, you can generate text responses to broad user prompts with built in content moderation. You can also specify it to perform common tasks like summarizing a piece of text, rewriting a piece of text for clarity, and converting text to a table format. Phi Silica is optimized for efficiency and performance on Windows Copilot+ PCs devices while still offering many of the capabilities found in Large Language Models (LLMs).

See Get started with Phi Silica in the Windows App SDK and API ref for Phi Silica in the Windows App SDK for more information.

Text Recognition (OCR)

Text recognition, also known as optical character recognition (OCR), APIs in Windows Copilot Runtime (WCR) can detect and extract text within images and convert it into machine readable character streams. These APIs can identify characters, words, lines, polygonal text boundaries, and provide confidence levels for each match. The set of WCR AI-assisted APIs benefit from NPU-assisted acceleration to perform faster and more accurately than the legacy Windows.Media.Ocr.OcrEngine APIs.

See Get Started with Text Recognition (OCR) in the Windows App SDK and API ref for AI-backed Text Recognition (OCR) in the Windows App SDK for more information.

Image Super Resolution

Using the 'ImageScaler' APIs you can increase the sharpness and clarity of an image and upscale the image up to 8x its original resolution.

See What can I do with Image Super Resolution? and API ref for AI imaging features in the Windows App SDK to get started.

Image Description

The Image Description APIs can be used to generate a text description of an image. The APIs are configurable to specify the length and type of the text description. Image descriptions may include a short caption or a long description for users with accessibility needs.

> **Note**
>
> When calling ImageDescriptionGenerator.DescribeAsync() in a Debug build, an error may occur that can be mitigated by continuing the build in Visual Studio.

See What can I do with Image Description? and API ref for AI imaging features in the Windows App SDK to learn more.

Image Segmentation

Using Image Segmentation APIs you can identify specific objects within an image. The model takes both an image and a "hints" object and returns a mask of the identified object.

See What can I do with Image Segmentation? and API ref for AI imaging features in the Windows App SDK to get started.

New APIs for Windowing

New `AppWindow` APIs make it easier to control your app windows and create a great experience. New capabilities include using `EnablePlacementPersistence` to automatically remember the size and position of your windows, using `SetTaskBarIcon` and `SetTitleBarIcon` to independently set the taskbar and titlebar icons, using `AppWindowTitleBar.PreferredTheme` to set the light/dark theme of the titlebar, and using `OverlappedPresenter.PreferredMinimum/MaximumSize` to set a minimum or maximum size for the window.

Other notable changes

- The missing C# projections for the new `BadgeNotifications` have been added so these APIs are now usable from C#.
- A class registration issue which prevented using the new `AppNotificationConferencingConfig` API has been fixed. Note that this enhanced user

experience for video or audio calling in notifications is only available on the latest Windows Insider releases of Windows.

New APIs

This release includes the following new and modified experimental APIs compared to 1.7-experimental2:

```
Microsoft.Graphics.Imaging

    ImageBuffer
    ImageBufferContract
    ImageObjectExtractor
    ImageObjectExtractorContract
    ImageObjectExtractorHint
    ImageScaler
    ImageScalerContract
    PixelFormat
```

```
Microsoft.UI.Content

    ChildSiteLink
        AutomationOption
        ProcessKeyboardInput
        ProcessPointerInput

    ContentAutomationOptions
    ContentIsland
        AutomationOption
        ProcessKeyboardInput
        ProcessPointerInput

    ContentSite
        ProcessKeyboardInput
        ProcessPointerInput

    ContentSiteView
        AutomationOption
        ProcessKeyboardInput
        ProcessPointerInput

    DesktopPopupSiteBridge
        AutomationOption

    IContentSiteAutomation
        AutomationOption
```

```
    IContentSiteInput
    ReadOnlyDesktopSiteBridge
        ProcessKeyboardInput
        ProcessPointerInput
```

```
Microsoft.UI.Windowing

    AppWindow
        EnablePlacementPersistence
        EnablePlacementPersistence
        GetCurrentPlacement
        SaveCurrentPlacement
        SetPlacement
        SetTaskBarIcon
        SetTaskBarIcon
        SetTitleBarIcon
        SetTitleBarIcon

    AppWindowTitleBar
        PreferredTheme

    OverlappedPresenter
        PreferredMaximumSize
        PreferredMinimumSize
        SetPreferredBounds

    PlacementPersistenceBehaviorFlags
    TitleBarTheme
```

```
Microsoft.Windows.AI.ContentModeration

    ContentFilterOptions
    ContentFilterOptionsContract
    ImageContentFilterSeverity
    SeverityLevel
    TextContentFilterSeverity
```

```
Microsoft.Windows.AI.Generative

    ImageDescriptionContract
    ImageDescriptionGenerator
    ImageDescriptionScenario
    LanguageModel
    LanguageModelContext
```

```
    LanguageModelContract
    LanguageModelOptions
    LanguageModelResponse
    LanguageModelResponseStatus
    LanguageModelSkill
```

```
Microsoft.Windows.SemanticSearch

    EmbeddingVector
    SemanticSearchContract
```

```
Microsoft.Windows.Vision

    BoundingBox
    DetectedLineStyle
    OrientationDetectionOptions
    RecognizedLine
    RecognizedLineStyle
    RecognizedText
    RecognizedWord
    TextRecognitionContract
    TextRecognizer
    TextRecognizerOptions
```

```
Microsoft.Windows.Workloads

    WorkloadPriority
    WorkloadsContract
```

Version 1.7 Experimental (1.7.0-experimental2)

Background Task Registration

A new `BackgroundTaskBuilder` API enables registering background tasks for Windows App SDK apps. For more info, see GitHub #4831.

New Notifications Features

New badge notification support allows showing a number or glyph badge on your app in the taskbar. For more info, see GitHub #4926.

> **Important**
>
> In this release, the C# projections are missing for the new `BadgeNotifications` APIs, which prevents using them from C#. The APIs are available in C++.

Video or audio calling can have an enhanced user experience in notifications. For more info, see GitHub #4783.

> **Important**
>
> This functionality is only available on the latest Windows Insider releases of Windows.

Other notable changes

- `RichEditBox` now supports math mode, via `RichEditTextDocument.SetMathMode` and `RichEditTextDocument.SetMath`.
- New `CompatibilityOptions` support will allow more control over how servicing changes affect apps. For more info, see GitHub #4976.

New APIs

This release includes the following new and modified experimental APIs:

```
Microsoft.Security.Authentication.OAuth

    AuthFailure
    AuthRequestParams
    AuthRequestResult
    AuthResponse
    ClientAuthentication
    CodeChallengeMethodKind
    OAuth2Manager
    OAuthContract
    TokenFailure
    TokenFailureKind
    TokenRequestParams
    TokenRequestResult
    TokenResponse
```

```
Microsoft.UI.Composition

    CompositionNotificationDeferral
    CompositionProjectedShadow
        MaxOpacity
        MinOpacity
        OpacityFalloff

    CompositionProjectedShadowCaster
        AncestorClip
        Mask

    CompositionProjectedShadowDrawOrder
    CompositionProjectedShadowReceiver
        DrawOrder
        Mask
```

```
Microsoft.UI.Composition.Experimental

    ExpCompositionVisualSurface
    ExpExpressionNotificationProperty
    IExpCompositionPropertyChanged
    IExpCompositionPropertyChangedListener
    IExpCompositor
    IExpVisual
```

```
Microsoft.UI.Content

    AutomationTreeOptions
    ChildSiteLink
    ContentAppWindowBridge
    ContentDisplayOrientations
    ContentEnvironmentStateChangedEventArgs
        DidDisplayScaleChange

    ContentExternalBackdropLink
    ContentExternalOutputLink
    ContentIsland
        AutomationTreeOption
        Children
        Connected
        ConnectionInfo
        ConnectRemoteEndpoint
        CreateForSystemVisual
        Disconnected
```

```
        FindAllForSystemCompositor
        FragmentRootAutomationProvider
        GetBySystemVisual
        InputCapabilities
        IsRemoteEndpointConnected
        LocalToClientTransformMatrix
        LocalToParentTransformMatrix
        NextSiblingAutomationProvider
        ParentAutomationProvider
        Popups
        PreviousSiblingAutomationProvider
        Root

    ContentIslandEnvironment
        CurrentOrientation
        DisplayScale
        NativeOrientation
        ThemeChanged

    ContentIslandStateChangedEventArgs
        DidLocalToClientTransformMatrixChange
        DidLocalToParentTransformMatrixChange

    ContentSite
        InputCapabilities
        LocalToClientTransformMatrix
        LocalToParentTransformMatrix
        SetContentNodeParent
        TryGetAutomationProvider

    ContentSiteAutomationProviderRequestedEventArgs
    ContentSiteEnvironment
        CurrentOrientation
        DisplayScale
        NativeOrientation
        NotifyThemeChanged

    ContentSiteEnvironmentView
        DisplayScale

    ContentSiteView
        AutomationTreeOption
        InputCapabilities
        LocalToClientTransformMatrix
        LocalToParentTransformMatrix

    CoreWindowSiteBridge
    CoreWindowTopLevelWindowBridge
    DesktopChildSiteBridge
        AcceptRemoteEndpoint
        ConnectionInfo
        CreateWithDispatcherQueue
        IsRemoteEndpointConnected
        RemoteEndpointConnecting
        RemoteEndpointDisconnected
```

```
        RemoteEndpointRequestedStateChanged

    DesktopPopupSiteBridge
    DesktopSiteBridge
        TryCreatePopupSiteBridge

    EndpointConnectionEventArgs
    EndpointRequestedStateChangedEventArgs
    IContentIslandEndpointConnectionPrivate
    IContentNodeOwner
    IContentSiteAutomation
    IContentSiteBridgeEndpointConnectionPrivate
    IContentSiteInput
    IContentSiteLink
    IContentSiteLink2
    InputCapabilities
    PopupWindowSiteBridge
    ProcessStarter
    ReadOnlyDesktopSiteBridge
    SystemVisualSiteBridge
```

```
Microsoft.UI.Input

    InputFocusNavigationHost
        GetForSiteLink

    InputKeyboardSource
        GetForWindowId

    InputLayoutPolicy
    InputLightDismissAction
        GetForIsland

    InputPointerActivationBehavior
    InputPointerSource
        ActivationBehavior
        DirectManipulationHitTest
        GetForVisual
        GetForWindowId
        RemoveForVisual
        TouchHitTesting
        TrySetDeviceKinds

    ProximityEvaluation
    TouchHitTestingEventArgs
```

```
Microsoft.UI.Input.Experimental
```

```
    ExpInputSite
    ExpPointerPoint
```

```

Microsoft.UI.Text

    RichEditTextDocument
        GetMath
        SetMath
        SetMathMode
```

```

Microsoft.UI.Windowing

    AppWindow
        DefaultTitleBarShouldMatchAppModeTheme

    DisplayArea
        GetMetricsFromWindowId
```

```

Microsoft.UI.Xaml

    XamlIsland
    XamlRoot
        TryGetContentIsland
```

```

Microsoft.UI.Xaml.Automation.Peers

    AutomationEvents
        Notification

    InkCanvasAutomationPeer
    PagerControlAutomationPeer
```

```

Microsoft.UI.Xaml.Controls

    ContentDialogPlacement
        UnconstrainedPopup

    DoInkPresenterWork
```

```
    ElementFactory
    FlowLayout
    FlowLayoutAnchorInfo
    FlowLayoutLineAlignment
    FlowLayoutState
    IApplicationViewSpanningRects

Version 1.7 Experimental (1.7.0-experimental1)

This is the latest release of the experimental channel.

To download, retarget your WinAppSDK NuGet version to `1.7.241114004-experimental1`.

New CameraCaptureUI API

A new CameraCaptureUI API makes it easier to capture photos and videos in your WinAppSDK app. For more info, see GitHub issue #4721.

New Authentication API

A new `OAuth2Manager` API provides a streamlined solution for web authentication, offering OAuth 2.0 capabilities with full feature parity across all Windows platforms supported by WinAppSDK. For more info, see GitHub issue #4772.

New Background Task support

A new `BackgroundTaskBuilder` API brings integrated support for background task registration to your WinAppSDK apps. For more info, see GitHub issue #4822.

New APIs for 1.7-experimental1

This release includes the following new and modified experimental APIs:

C#

```
Microsoft.Security.Authentication.OAuth

    AuthFailure
    AuthRequestParams
    AuthRequestResult
    AuthResponse
    ClientAuthentication
    CodeChallengeMethodKind
    OAuth2Manager
    OAuthContract
    TokenFailure
    TokenFailureKind
    TokenRequestParams
    TokenRequestResult
    TokenResponse
```

C#

```
Microsoft.UI.Composition

    CompositionNotificationDeferral
    CompositionProjectedShadow
        MaxOpacity
        MinOpacity
        OpacityFalloff

    CompositionProjectedShadowCaster
        AncestorClip
        Mask

    CompositionProjectedShadowDrawOrder
    CompositionProjectedShadowReceiver
        DrawOrder
        Mask
```

C#

```
Microsoft.UI.Composition.Experimental

    ExpCompositionVisualSurface
    ExpExpressionNotificationProperty
    IExpCompositionPropertyChanged
    IExpCompositionPropertyChangedListener
    IExpCompositor
    IExpVisual
```

C#

```
Microsoft.UI.Content

    AutomationOptions

```

Bug fixes

This release includes the following bug fixes:

- Changed `SplitButton` so touch input now matches the behavior of mouse input. For more info, see GitHub issue #178.

- Changed cascading menus so sub menus now open immediately if clicked. For more info, see GitHub issue #939.
- Fixed an issue where opening a `ComboBox` which is in a flyout closes all flyouts. For more info, see GitHub issue #1467.
- Fixed an issue where `SwipeControl` would randomly crash in a `ListView`. For more info, see GitHub issue #2527.
- Fixed an issue where drag-and-drop only a `ListViewItem` would leave it in the wrong visual state. For more info, see GitHub issue #3458.
- Fixed an issue in `StackLayout` so that it respects the ItemsRepeater.HorizontalAlignment and ItemsRepeater.VerticalAlignment properties (when StackLayout.Orientation is Vertical and Horizontal respectively). The old layout behaved as if the ItemsRepeater alignment was Stretch. With the fix, the layout results in items aligned to the right when the Right alignment is used, for example. For more info, see GitHub issue #3842.
- Fixed an issue where deleting items in the `ItemsRepeater`'s source would not generate items which moved up into view. For more info, see GitHub issue #6661.
- Fixed an issue where the right Alt key would not show keytips for Access Keys. For more info, see GitHub issue #8447. **Note:** This may result in key events for the right Alt key no longer being delivered to handles in the app or controls.
- Fixed a crash where `UniformGridLayout` would sometimes pick a wrong layout anchor and cause infinite layout passes when scrolling backwards. For more info, see GitHub issue #9199.
- Fixed an issue where setting `NavigationFailedEventArgs.Handled` to True would still throw an exception. For more info, see GitHub issue #9632.
- Fixed an issue where `TabView` would not apply any specified `CornerRadius`. For more info, see GitHub issue #9846.
- Fixed a potential layout cycle crash in `StackLayout`. For more info, see GitHub issue #9852.
- Fixed a potential crash in `ItemsView` when removing items. For more info, see GitHub issue #9868.

Experimental channel release notes for the Windows App SDK 1.6

Article • 11/21/2024

> **ⓘ Important**
>
> The experimental channel is **not supported** for use in production environments, and apps that use the experimental releases cannot be published to the Microsoft Store.

The experimental channel provides releases of the Windows App SDK that include experimental channel features that are in early stages of development. APIs for experimental features have the Experimental attribute. If you call an experimental API in your code, you will receive a build-time warning. All APIs in the experimental channel might have breaking changes in future releases, but experimental APIs are especially subject to change. Experimental features may be removed from the next release, or may never be released.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on experimental releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest experimental channel release:

- Latest experimental channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.6 Experimental (1.6.0-experimental2)

This is the latest release of the experimental channel.

To download, retarget your WinAppSDK NuGet version to `1.6.240701003-experimental2`.

> **Note**
>
> Phi Silica and OCR APIs are not included in this release. These will be coming in a future 1.6 release.

Native AOT support updates

In 1.6-experimental1, the XAML compiler was generating `XamlTypeInfo.g.cs` with code that wasn't safe for AOT/Trimming. This relates to GitHub issue #9675, though it does not fully fix that issue.

Changed Edge WebView2 SDK Integration

The Windows App SDK now consumes the Edge WebView2 SDK as a NuGet reference rather than embedding a hardcoded version of the Edge WebView2 SDK. The new model allows apps to choose a newer version of the `Microsoft.Web.WebView2` package instead of being limited to the version with which the Windows App SDK was built. The new model also allows apps to reference NuGet packages which also reference the Edge WebView2 SDK. For more info, see GitHub issue #5689.

New Package Deployment APIs

The Package Management API has received several enhancements including Is*ReadyOrNewerAvailable*(), EnsureReadyOptions.RegisterNewerIfAvailable, Is*Provisioned*(), IsPackageRegistrationPending(), and several bug fixes. See PackageManagement.md and Pull Request #4453 for more details.

Other notable changes

- Starting with 1.6-experimental2, the latest WinUI 3 source will now publish to the main branch in the microsoft-ui-xaml GitHub repo, which will enable source searching in that repo.
- We added a new `ColorHelper.ToDisplayName()` API, filling that gap from UWP.
  - **Known issue:** Some language translations have character encoding issues. This will be fixed in the next 1.6 release.
- Added a new `Microsoft.Windows.Globalization.ApplicationLanguages` class, which notably includes a new `PrimaryLanguageOverride` feature. For more info, see GitHub issue #4523.

- New extensions enable Widget Providers to provide Widgets with web content and announcements for Widgets.

New APIs for 1.6-experimental2

1.6-experimental2 includes the following new APIs. These APIs are not experimental, but are not yet included in a stable release version of the WinAppSDK.

```
C#

Microsoft.UI.Xaml.Controls

    PipsPager
        WrapMode
        WrapModeProperty

    PipsPagerWrapMode
```

```
C#

Microsoft.Windows.Globalization

    ApplicationLanguages
```

```
C#

Microsoft.Windows.Management.Deployment

    EnsureReadyOptions
        RegisterNewerIfAvailable

    PackageDeploymentFeature
    PackageDeploymentManager
        IsPackageDeploymentFeatureSupported
        IsPackageProvisioned
        IsPackageProvisionedByUri
        IsPackageReadyOrNewerAvailable
        IsPackageReadyOrNewerAvailableByUri
        IsPackageSetProvisioned
        IsPackageSetReadyOrNewerAvailable

    PackageReadyOrNewerAvailableStatus
```

Additional 1.6-experimental2 APIs

This release includes the following new and modified experimental APIs:

Known issues

- For TabView tab tear-out, pointer input behavior for *CanTearOutTabs* is incorrect on monitors with scale factor different from 100%. This will be fixed in the next 1.6 release.

Bug fixes

- Fixed an issue from 1.6-experimental1 where `NumberBox` wasn't using the correct foreground and background colors. For more info, see GitHub issue #9714.
- Fixed an issue where duplicate `KeyUp` events were raised for arrow and tab keys. For more info, see GitHub issue #9399.
- Fixed an issue where the `PowerManager.SystemSuspendStatusChanged` event was unusable to get the `SystemSuspendStatus`. For more info, see GitHub issue #2833.
- Fixed an issue where initial keyboard focus was not correctly given to a `WebView2` when that was the only control in the window.
- Fixed an issue when using `ExtendsContentIntoTitleBar=true` where the Min/Max/Close buttons did not correctly appear in the UI Automation, which prevented Voice Access from showing numbers for those buttons.
- Fixed an issue where an app might crash in a lock check due to unexpected reentrancy.
- Fixed an issue from 1.6-experimental1 where `TitleBar` only showed the Icon and Title because some elements did not show up on load.
- Fixed an issue where `Hyperlink` colors did not correctly update when switching into a high contrast theme.
- Fixed an issue where changing the collection of a `ListView` in a background window may incorrectly move that window to the foreground and take focus.
- Fixed an issue from 1.6-experimental1 where setting `AcrylicBrush.TintLuminosityOpacity` in .xaml in a class library project would crash with a type conversion error.
- Fixed an issue where calling `ItemsRepeater.StartBringIntoView` could sometimes cause items to disappear.
- Fixed an issue where touching and dragging on a `Button` in a `ScrollViewer` would leave it in a pressed state.

- Updated IntelliSense, which was missing information for many newer types and members.

Version 1.6 Experimental (1.6.0-experimental1)

This is the latest release of the experimental channel.

To download, retarget your WinAppSDK NuGet version to `1.6.240531000-experimental1`.

Required C# project changes for 1.6-experimental1

In 1.6-experimental1, Windows App SDK managed apps require Microsoft.Windows.SDK.NET.Ref `*.*.*.35-preview` (or later), which can be specified via WindowsSdkPackageVersion in your `csproj` file. For example:

XML

```
<Project Sdk="Microsoft.NET.Sdk">
   <PropertyGroup>
       <OutputType>WinExe</OutputType>
       <TargetFramework>net8.0-windows10.0.22621.0</TargetFramework>
       <TargetPlatformMinVersion>10.0.17763.0</TargetPlatformMinVersion>
       <WindowsSdkPackageVersion>10.0.22621.35-
preview</WindowsSdkPackageVersion>
   <PropertyGroup>
   ...
```

In addition, Windows App SDK managed apps using C#/WinRT should update to Microsoft.Windows.CsWinRT `2.1.0-prerelease.240602.1` (or later).

Native AOT support

> ⓘ **Note**
>
> For Windows App SDK 1.6.0 stable, the following guidance is obsolete. Projects should instead simply set `PublishAot` to **true** unconditionally.

The .NET `PublishAot` project property is now supported for native Ahead-Of-Time compilation. For details, see Native AOT Deployment. Because AOT builds on Trimming support, much of the following trimming-related guidance applies to AOT as well.

For `PublishAot` support, in addition to the C# project changes described in the previous section you'll also need a package reference to Microsoft.Windows.CsWinRT `2.1.0-prerelease.240602.1` (or later) to enable the source generator from that package.

Because the Windows App SDK invokes publishing targets when F5 deploying, we recommend enabling `PublishAot` at NuGet restore time by adding this to your `csproj` file:

XML

```
<PublishAot
Condition="'$(ExcludeRestorePackageImports)'=='true'">true</PublishAot>
```

In addition, we recommend conditionally enabling `PublishAot` when publishing release configurations, either in publish profiles or the project:

XML

```
<PublishAot Condition="'$(Configuration)'=='Release'">true</PublishAot>
```

Resolving AOT Issues

In this release, the developer is responsible for ensuring that all types are properly rooted to avoid trimming (such as with reflection-based `{Binding}` targets). Later releases will enhance both C#/WinRT and the XAML Compiler to automate rooting where possible, alert developers to trimming risks, and provide mechanisms to resolve.

Partial Classes

C#/WinRT also includes `PublishAot` support in version 2.1.0-prerelease.240602.1. To enable a class for AOT publishing with C#/WinRT, it must first be marked `partial`. This allows the C#/WinRT AOT source analyzer to attribute the classes for static analysis. Only classes (which contain methods, the targets of trimming) require this attribute.

Reflection-Free Techniques

To enable AOT compatibility, reflection-based techniques should be replaced with statically typed serialization, AppContext.BaseDirectory, typeof(), etc. For details, see Introduction to trim warnings.

Rooting Types

Until full support for `{Binding}` is implemented, types may be preserved from trimming as follows: Given project `P` consuming assembly `A` with type `T` in namespace `N`, which is only dynamically referenced (so normally trimmed), `T` can be preserved via:

`P.csproj`:

XML

```xml
<ItemGroup>
    <TrimmerRootDescriptor Include="ILLink.Descriptors.xml" />
</ItemGroup>
```

`ILLink.Descriptors.xml`:

XML

```xml
<?xml version="1.0" encoding="utf-8"?>
<linker>
    <assembly fullname="A">
        <type fullname="N.T" preserve="all" />
    </assembly>
</linker>
```

For complete root descriptor XML expression syntax, see Root Descriptors.

> ⓘ **Note**
>
> Dependency packages that have not yet adopted AOT support may exhibit runtime issues.

Improved TabView tab tear-out

`TabView` supports a new `CanTearOutTabs` mode which provides an enhanced experience for dragging tabs and dragging out to a new window. When this new option is enabled, tab dragging is very much like the tab drag experience in Edge and Chrome, where a new window is immediately created during the drag, allowing the user to drag it to the edge of the screen to maximize or snap the window in one smooth motion. This implementation also doesn't use drag-and-drop APIs, so it isn't impacted by any limitations in those APIs. Notably, tab tear-out is supported in processes running elevated as Administrator.

Known issue: In this release, pointer input behavior for `CanTearOutTabs` is incorrect on monitors with scale factor different than 100%. This will be fixed in the next 1.6 release.

New TitleBar control

A new `TitleBar` control makes it easy to create a great, customizable titlebar for your app with the following features:

- Configurable Icon, Title, and Subtitle properties
- An integrated back button
- The ability to add a custom control like a search box
- Automatic hiding and showing of elements based on window width
- Affordances for showing active or inactive window state
- Support for default titlebar features including draggable regions in empty areas, theme responsiveness, default caption (min/max/close) buttons, and built-in accessibility support

The `TitleBar` control is designed to support various combinations of titlebars, making it flexible to create the experience you want without having to write a lot of custom code. We took feedback from the community toolkit titlebar prototype and look forward to additional feedback!

Known issue: In this release, the `TitleBar` only shows the Icon and Title due to an issue where some elements don't show up on load. To work around this, use the following code to load the other elements (Subtitle, Header, Content, and Footer):

C#

```
public MainWindow()
  {
      this.InitializeComponent();
      this.ExtendsContentIntoTitleBar = true;
      this.SetTitleBar(MyTitleBar);

      MyTitleBar.Loaded += MyTitleBar_Loaded;
  }

  private void MyTitleBar_Loaded(object sender, RoutedEventArgs e)
  {
      // Parts get delay loaded. If you have the parts, make them visible.
      VisualStateManager.GoToState(MyTitleBar, "SubtitleTextVisible",
false);
      VisualStateManager.GoToState(MyTitleBar, "HeaderVisible", false);
      VisualStateManager.GoToState(MyTitleBar, "ContentVisible", false);
      VisualStateManager.GoToState(MyTitleBar, "FooterVisible", false);

      // Run layout so we re-calculate the drag regions.
      MyTitleBar.InvalidateMeasure();
  }
```

This issue will be fixed in the next 1.6 release.

Other notable changes

- Unsealed `ItemsWrapGrid`. This should be a backward-compatible change.
- `PipsPager` supports a new mode where it can wrap between the first and list items.
- `RatingControl` is now more customizable, by moving some hard-coded style properties to theme resources. This allows apps to override these values to better customize the appearance of RatingControl.

New APIs for 1.6-experimental1

1.6-experimental1 includes the following new APIs. These APIs are not experimental, but are not yet included in a stable release version of the WinAppSDK.

```
C#

Microsoft.UI.Xaml.Controls

    PipsPager
        WrapMode
        WrapModeProperty

    PipsPagerWrapMode
        None
        Wrap
```

Additional 1.6-experimental1 APIs

This release includes the following new and modified experimental APIs:

```
C#

Microsoft.UI.Content

    ChildContentLink
    ContentExternalOutputLink
        IsAboveContent

    ContentIsland
        Children
        Create
        FindAllForCompositor
        GetByVisual
        Offset
        RotationAngleInDegrees
```

```
    ContentSite
        Offset
        RotationAngleInDegrees

    ContentSiteView
        Offset
        RotationAngleInDegrees

    IContentLink
    IContentSiteBridge2
    ReadOnlyDesktopSiteBridge
```

C#

```
Microsoft.UI.Input

    EnteredMoveSizeEventArgs
    EnteringMoveSizeEventArgs
    ExitedMoveSizeEventArgs
    InputNonClientPointerSource
        EnteredMoveSize
        EnteringMoveSize
        ExitedMoveSize
        WindowRectChanged
        WindowRectChanging

    MoveSizeOperation
    WindowRectChangedEventArgs
    WindowRectChangingEventArgs
```

C#

```
Microsoft.UI.Windowing

    AppWindow
        DefaultTitleBarShouldMatchAppModeTheme
```

C#

```
Microsoft.UI.Xaml

    XamlRoot
        CoordinateConverter
        TryGetContentIsland
```

C#

```
Microsoft.UI.Xaml.Controls

    ScrollingViewChangingEventArgs
    ScrollView
        ViewChanging

    StackLayout
        IsVirtualizationEnabled
        IsVirtualizationEnabledProperty

    TabView
        CanTearOutTabs
        CanTearOutTabsProperty
        ExternalTornOutTabsDropped
        ExternalTornOutTabsDropping
        TabTearOutRequested
        TabTearOutWindowRequested

    TabViewExternalTornOutTabsDroppedEventArgs
    TabViewExternalTornOutTabsDroppingEventArgs
    TabViewTabTearOutRequestedEventArgs
    TabViewTabTearOutWindowRequestedEventArgs
    TitleBar
    TitleBarAutomationPeer
    TitleBarTemplateSettings
```

C#

```
Microsoft.UI.Xaml.Controls.Primitives

    ScrollPresenter
        ViewChanging
```

Other known issues

- Non-XAML applications that use `Microsoft.UI.Content.ContentIslands` and do not handle the *ContentIsland.AutomationProviderRequested* event (or return *nullptr* as the automation provider) will crash if any accessibility or UI automation tool is enabled such as Voice Access, Narrator, Accessibility Insights, Inspect.exe, etc.

Bug fixes

This release includes the following bug fixes:

- Fixed an issue where clicking in an empty area of a `ScrollViewer` would always move focus to the first focusable control in the `ScrollViewer` and scroll that

control into view. For more info, see GitHub issue #597.

- Fixed an issue where the `Window.Activated` event sometimes fired multiple times. For more info, see GitHub issue #7343.
- Fixed an issue setting the `NavigationViewItem.IsSelected` property to `true` prevents its children from showing when expanded. For more info, see GitHub issue #7930.
- Fixed an issue where `MediaPlayerElement` would not properly display captions with `None` or `DropShadow` edge effects. For more info, see GitHub issue #7981.
- Fixed an issue where the `Flyout.ShowMode` property was not used when showing the flyout. For more info, see GitHub issue #7987.
- Fixed an issue where `NumberBox` would sometimes have rounding errors. For more info, see GitHub issue #8780.
- Fixed an issue where using a library compiled against an older version of WinAppSDK can hit a trying to find a type or property. For more info, see GitHub issue #8810.
- Fixed an issue where initial keyboard focus is not set when launching a window. For more info, see GitHub issue #8816.
- Fixed an issue where `FlyoutShowMode.TransientWithDismissOnPointerMoveAway` didn't work after the first time it is shown. For more info, see GitHub issue #8896.
- Fixed an issue where some controls did not correctly template bind `Foreground` and `Background` properties. For more info, see GitHub issue #7070, #9020, #9029, #9083 and #9102.
- Fixed an issue where `ThemeResource`s used in `VisualStateManager` setters wouldn't update on theme change. This commonly affected controls in flyouts. For more info, see GitHub issue #9198.
- Fixed an issue where `WebView` would lose key focus, resulting in extra blur/focus events and other issues. For more info, see GitHub issue #9288.
- Fixed an issue where `NavigationView` can show a binding error in debug output. For more info, see GitHub issue #9384.
- Fixed an issue where SVG files defining a negative viewbox no longer rendered. For more info, see GitHub issue #9415.
- Fixed an issue where changing `ItemsView.Layout` orientation caused an item to be removed. For more info, see GitHub issue #9422.
- Fixed an issue where scrolling a `ScrollView` generated a lot of debug output. For more info, see GitHub issue #9434.
- Fixed an issue where `MapContorl.InteractiveControlsVisible` does not work properly. For more info, see GitHub issue #9486.

- Fixed an issue where `MapControl.MapElementClick` event doesn't properly fire. For more info, see GitHub issue #9487.
- Fixed an issue where x:Bind doesn't check for null before using a weak reference, which can result in a crash. For more info, see GitHub issue #9551.
- Fixed an issue where changing the `TeachingTip.Target` property doesn't correctly update its position. For more info, see GitHub issue #9553.
- Fixed an issue where dropdowns did not respond in WebView2. For more info, see GitHub issue #9566.
- Fixed a memory leak when using `GeometryGroup`. For more info, see GitHub issue #9578.
- Fixed an issue where scrolling through a very large number of items from an `ItemRepeater` in a `ScrollView` can cause blank render frames. For more info, see GitHub issue #9643.
- Fixed an issue where `SceneVisual` wasn't working.

Experimental channel release notes for the Windows App SDK 1.5

Article • 06/04/2024

> **ⓘ Important**
>
> The experimental channel is **not supported** for use in production environments, and apps that use the experimental releases cannot be published to the Microsoft Store.

The experimental channel provides releases of the Windows App SDK that include experimental channel features that are in early stages of development. APIs for experimental features have the Experimental attribute. If you call an experimental API in your code, you will receive a build-time warning. All APIs in the experimental channel might have breaking changes in future releases, but experimental APIs are especially subject to change. Experimental features may be removed from the next release, or may never be released.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on experimental releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest experimental channel release:

Version 1.5 Experimental (1.5.0-experimental2)

This is the latest release of the experimental channel. To download, retarget your WinAppSDK NuGet version to `1.5.240124002-experimental2`.

Bug fixes

This release includes the following bug fixes:

- Fixed an issue causing apps to crash on startup when using a custom `NavigationViewItem`. For more info, see GitHub issue #8814.
- Fixed a `NavigationView` issue where the ellipsis button would incorrectly generate an error. For more info, see GitHub issue #8380.
- Fixed an issue where a `SystemBackdrop` would not render properly in a multi-window app. For more info, see GitHub issue #8423.
- Fixed a duplication issue when inserting into the beginning of an `ObservableCollection`. For more info, see GitHub issue #8370.

New APIs for 1.5-experimental2

1.5-experimental2 includes the following new APIs. These APIs are not experimental, but are not yet included in a stable release version of the WinAppSDK.

```
C#

Microsoft.Graphics.DirectX

    DirectXPixelFormat
        A4B4G4R4
```

```
C#

Microsoft.UI.Xaml

    DebugSettings
        LayoutCycleDebugBreakLevel
        LayoutCycleTracingLevel

    LayoutCycleDebugBreakLevel
    LayoutCycleTracingLevel
```

```
C#

Microsoft.UI.Xaml.Automation.Peers

    SelectorBarItemAutomationPeer
```

```
C#

Microsoft.UI.Xaml.Controls

    MapControl
```

```
    MapControlMapServiceErrorOccurredEventArgs
    MapElement
    MapElementClickEventArgs
    MapElementsLayer
    MapIcon
    MapLayer
    SelectorBar
    SelectorBarItem
    SelectorBarSelectionChangedEventArgs
    WebView2
        EnsureCoreWebView2Async
        EnsureCoreWebView2Async
```

C#

```
Microsoft.Windows.Management.Deployment

    EnsureReadyOptions
    PackageDeploymentManager
        AddPackageSetAsync
        DeprovisionPackageAsync
        DeprovisionPackageByUriAsync
        DeprovisionPackageSetAsync
        EnsurePackageReadyAsync
        EnsurePackageReadyByUriAsync
        EnsurePackageSetReadyAsync
        IsPackageReady
        IsPackageReadyByUri
        IsPackageRegistrationPending
        IsPackageRegistrationPendingForUser
        ProvisionPackageAsync
        ProvisionPackageByUriAsync
        ProvisionPackageSetAsync
        RegisterPackageAsync
        RegisterPackageByUriAsync
        RegisterPackageSetAsync
        RemovePackageByUriAsync
        RepairPackageAsync
        RepairPackageByUriAsync
        RepairPackageSetAsync
        ResetPackageAsync

        FindPackageVolumes
        IsRepairNeeded
        Repair

    ProvisionPackageOptions
    RegisterPackageOptions
        DependencyPackageFamilyNames

    RemovePackageOptions
        FailIfNotFound
```

Additional 1.5-experimental2 APIs

This release includes the following new and modified experimental APIs:

C#

```
Microsoft.UI.Xaml

    Application
        DispatcherShutdownMode

    DispatcherShutdownMode
    XamlIsland
        SystemBackdrop
```

C#

```
Microsoft.UI.Xaml.Hosting

    WindowsXamlManager
        IsXamlRunningOnCurrentThread
        XamlShutdownCompletedOnThread

    XamlShutdownCompletedOnThreadEventArgs
```

C#

```
Microsoft.Windows.System.Workloads

    IWorkloadHandler
    Workload
    WorkloadManager
```

```
    WorkloadProgress
    WorkloadProgressStatus
    WorkloadResult
    WorkloadsContract
    WorkloadStatus
```

Version 1.5 Experimental (1.5.0-experimental1)

This is the latest release of the experimental channel. To download, retarget your WinAppSDK NuGet version to `1.5.231202003-experimental1`.

New APIs for 1.5-experimental1

1.5-experimental1 includes the following new APIs. These APIs are not experimental, but are not yet included in a stable release version of the WinAppSDK.

C#

```
Microsoft.Windows.Widgets.Feeds.Providers
    CustomQueryParametersRequestedArgs
    CustomQueryParametersUpdateOptions
    FeedDisabledArgs
    FeedEnabledArgs
    FeedManager
    FeedProviderDisabledArgs
    FeedProviderEnabledArgs
    FeedProviderInfo
    IFeedManager
    IFeedProvider
```

Additional 1.5-experimental1 APIs

This release includes the following new and modified experimental APIs:

C#

```
Microsoft.UI.Content

    ContentIsland
        ConnectionInfo
        ConnectRemoteEndpoint
        IsRemoteEndpointConnected

    ContentIslandEnvironment
        CurrentOrientation
        DisplayScale
```

```
        NativeOrientation
        ThemeChanged

    ContentSiteEnvironment
        CurrentOrientation
        DisplayScale
        NativeOrientation
        NotifyThemeChanged

    DesktopChildSiteBridge
        AcceptRemoteEndpoint
        ConnectionInfo
        IsRemoteEndpointConnected
        RemoteEndpointConnecting
        RemoteEndpointDisconnected
        RemoteEndpointRequestedStateChanged

    EndpointConnectionEventArgs
    EndpointRequestedStateChangedEventArgs
    IContentIslandEndpointConnectionPrivate
    IContentSiteBridgeEndpointConnectionPrivate
    ProcessStarter
    SystemVisualSiteBridge
        IsClosed
```

C#

```
Microsoft.UI.Input

    FocusNavigationReason
    FocusNavigationRequest
    FocusNavigationRequestEventArgs
    FocusNavigationResult
    InputFocusController
        DepartFocus
        NavigateFocusRequested

    InputFocusNavigationHost
```

C#

```
Microsoft.UI.Xaml

    DebugSettings
        LayoutCycleDebugBreaks
        LayoutCycleTracing

    LayoutCycleDebugBreakLevel
    LayoutCycleTracingLevel
    XamlIsland
```

C#

```
Microsoft.UI.Xaml.Controls

    SelectionModel
        SelectAllFlat
```

C#

```
Microsoft.UI.Xaml.Core.Direct

    XamlPropertyIndex
        FlyoutBase_SystemBackdrop
        Popup_SystemBackdrop
```

C#

```
Microsoft.Windows.Management.Deployment

    AddPackageOptions
    AddPackageSetOptions
    DeploymentPriority
    DeploymentProcessingModel
    EnsureIsReadyOptions
    FindPackageSetOptions
    PackageDeploymentContract
    PackageDeploymentManager

Version 1.4 Experimental (1.4.0-experimental1)

This is the latest release of the experimental channel. To download, retarget your WinAppSDK NuGet version to `1.4.230518007-experimental1`.

Bug fixes

This release contains miscellaneous fixes, including the following:

- Fixed an issue where enabling the debug settings framerate counter in a new WinUI desktop application caused an access violation. For more information, see issue 2835 on GitHub.
- Fixed an issue where horizontal scrolling on a touchpad did not work in a WebView2 web page. For more information, see issue 7772 on GitHub.

Additional Experimental APIs

This release includes the following new and modified experimental APIs:

```
C#

Microsoft.UI

   IClosableNotifier
```

```
C#

Microsoft.UI.Composition.SystemBackdrops

   DesktopAcrylicController
       Closed
       FrameworkClosed
       Kind

   DesktopAcrylicKind
   MicaController
       Closed
       FrameworkClosed
```

```
C#

Microsoft.UI.Content

   ContentAppWindowBridge
       SettingChanged

   ContentEnvironmentSettingChangedEventArgs
   ContentExternalBackdropLink
   ContentExternalOutputLink
       ExternalOutputBorderMode

   ContentIsland
       FrameworkClosed

   ContentIslandWindow
```

```
        SettingChanged

    ContentSite
        FrameworkClosed

    ContentSiteWindow
        NotifySettingChanged
        SettingChanged

    CoreWindowTopLevelWindowBridge
        SettingChanged

    DesktopSiteBridge
        Closed
        FrameworkClosed

    IContentWindow
        SettingChanged

    SystemVisualSiteBridge
        Closed
        FrameworkClosed
```

C#

```
Microsoft.UI.Input

    InputLayoutPolicy
    InputNonClientPointerSource
        ConfigurationChanged
        GetForWindowId

    NonClientRegionConfigurationChangedEventArgs
```

C#

```
Microsoft.UI.System

    ThemeSettings
```

C#

```
Microsoft.UI.Windowing

    DisplayArea
        GetMetricsFromWindowId
```

C#

```
Microsoft.UI.Xaml

   XamlRoot
       ContentWindow
```

C#

```
Microsoft.UI.Xaml.Controls

   ItemContainer
       Child
       ChildProperty

   ItemContainerMultiSelectMode
       Extended

   ItemsView
       Animator
       AnimatorProperty

   MenuFlyoutPresenter
       SystemBackdrop
       SystemBackdropProperty

   RiverFlowLayout
       InvalidateItemsInfo
       RequestedRangeCount
       RequestedRangeStartIndex

   RiverFlowLayoutElementAnimator
```

C#

```
Microsoft.UI.Xaml.Controls.Primitives

   CommandBarFlyoutCommandBar
       SystemBackdrop
       SystemBackdropProperty
```

C#

```
Microsoft.UI.Xaml.Input

   AccessKeyManager
       EnterDisplayMode
```

Experimental channel release notes for the Windows App SDK 1.3

Article • 05/23/2024

> **ⓘ Important**
>
> The experimental channel is **not supported** for use in production environments, and apps that use the experimental releases cannot be published to the Microsoft Store.

The experimental channel provides releases of the Windows App SDK that include experimental channel features that are in early stages of development. APIs for experimental features have the Experimental attribute. If you call an experimental API in your code, you will receive a build-time warning. All APIs in the experimental channel might have breaking changes in future releases, but experimental APIs are especially subject to change. Experimental features may be removed from the next release, or may never be released.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on experimental releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest experimental channel release:

- Latest experimental channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.3 Experimental (1.3.0-experimental1)

This is the latest release of the experimental channel. To download, retarget your WinAppSDK NuGet version to `1.3.230202101-experimental1`.

XAML Backdrop APIs

With properties built in to the XAML Window, Mica & Background Acrylic backdrops are now easier to use in your WinUI 3 app.

See the Xaml Backdrop API spec on GitHub for more information about the **Window.SystemBackdrop** property.

Of note in this release, you're able to set the backdrop only in code-behind, as below. Setting `<Window.SystemBackdrop>` in markup results in a compile error.

Additionally, the Xaml Backdrop APIs are currently missing an 'experimental' tag as they are under active development.

C#

```
public MainWindow()
{
    this.InitializeComponent();

    this.SystemBackdrop = new MicaBackdrop();
}
```

Window.AppWindow

Replacing several lines of boilerplate code, you're now able to use AppWindow APIs directly from a **Window** through `Window.AppWindow`. See the Window.AppWindow API spec on GitHub for additional background and usage information.

New features from across WinAppSDK

- `ApplicationModel.DynamicDependency`: `PackageDependency.PackageGraphRevisionId` that replaces the deprecated MddGetGenerationId.
- Environment Manager: `EnvironmentManager.AreChangesTracked` to inform you whether changes to the environment manager are able to be tracked in your application. See the Environment Manager API spec on GitHub for more information.
- MRT Core: A new event, `Application.ResourceManagerInitializing` allows your app to provide its own implementation of the `IResourceManager` interface, and gives you access to the ResourceManager that WinUI uses to resolve resource URIs.
- With the latest experimental VSIX, you're now able to convert your app between unpackaged and packaged through the Visual Studio menu instead of in your project file.

- A new event, `DebugSettings.XamlResourceReferenceFailed` is now raised when a referenced Static/ThemeResource lookup can't be resolved. This event gives access to a trace that details where the framework searched for that key in order to better enable you to debug Static & ThemeResource lookup failures. For more information, see issues 4972, 2350, and 6073 on GitHub.

Bug fixes

- Fixed issues with touch input causing the soft keyboard to not appear on text boxes. For more information, see issue 6291 on GitHub.
- Fixed issue causing an ItemsRepeater with an IElementFactory as its ItemTemplate to throw an ArgumentException. For more info, see issue 4705 on GitHub.

Additional Experimental APIs

This release also includes several APIs that are in early development.

The list below details the APIs introduced in this experimental release that we don't plan to ship in the 1.3.0 stable release.

```
C#

**Microsoft.UI.Content**

    DesktopSiteBridge
        GetInputEnabledToRoot
        GetVisibleToRoot
        InputEnabled
```

```
C#

**Microsoft.UI.Dispatching**

    DispatcherQueue
        FrameworkShutdownStarting
```

```
C#

**Microsoft.UI.Input**

    InputLightDismissAction
        GetForIsland

    InputNonClientPointerSource
    InputPointerActivationBehavior
```

```
    InputPointerSource
        ActivationBehavior

    NonClientRegionCaptionTappedEventArgs
    NonClientRegionHoverEventArgs
    NonClientRegionKind
```

C#

```
**Microsoft.UI.Input.DragDrop**

    DragDropManager
    DragDropModifiers
    DragInfo
    DragOperation
    DragUIContentMode
    DragUIOverride
    DropOperationTargetRequestedEventArgs
    IDropOperationTarget
```

C#

```
**Microsoft.UI.Xaml.Automation.Peers**

    ItemContainerAutomationPeer
    ItemsViewAutomationPeer
```

C#

```
**Microsoft.UI.Xaml.Controls**

    AnnotatedScrollBar
    AnnotatedScrollBarLabel
    AnnotatedScrollBarScrollEventArgs
    AnnotatedScrollBarScrollEventType
    AnnotatedScrollBarScrollOffsetRequestedEventArgs
    AnnotatedScrollBarSubLabelRequestedEventArgs
    AnnotatedScrollBarValueRequestedEventArgs
    ElementFactory
        GetElement
        GetElementCore
        RecycleElement
        RecycleElementCore

    IndexBasedLayoutOrientation
    ItemContainer
    ItemContainerInteractionTrigger
    ItemContainerInvokedEventArgs
    ItemContainerMultiSelectMode
    ItemContainerUserInvokeMode
    ItemContainerUserSelectMode
```

```
    ItemsView
    ItemsViewItemInvokedEventArgs
    ItemsViewItemInvokeMode
    ItemsViewSelectionMode
    Layout
        IndexBasedLayoutOrientation

    NonVirtualizingLayout
        IndexBasedLayoutOrientationCore

    RiverFlowLayout
    RiverFlowLayoutItemsInfoRequestedEventArgs
    RiverFlowLayoutItemsJustification
    RiverFlowLayoutItemsStretch
    VirtualizingLayout
        IndexBasedLayoutOrientationCore

    VirtualizingLayoutContext
        VisibleRect
        VisibleRectCore
```

C#

```
**Microsoft.Graphics.Display**

    DisplayInformation
        AngularOffsetFromNativeOrientation
        DpiChanged
        OrientationChanged
        RawDpi
        RawPixelsPerViewPixel

    DisplayOrientation
```

C#

```
**Microsoft.UI.Xaml.Hosting**

    DesktopWindowXamlSource
        CreateSiteBridge
        SiteBridge
        SystemBackdrop
```

Experimental channel release notes for the Windows App SDK 1.2

Article • 05/23/2024

> **ⓘ Important**
>
> The experimental channel is **not supported** for use in production environments, and apps that use the experimental releases cannot be published to the Microsoft Store.

The experimental channel provides releases of the Windows App SDK that include experimental channel features that are in early stages of development. APIs for experimental features have the Experimental attribute. If you call an experimental API in your code, you will receive a build-time warning. All APIs in the experimental channel might have breaking changes in future releases, but experimental APIs are especially subject to change. Experimental features may be removed from the next release, or may never be released.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on experimental releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest experimental channel release:

- Latest experimental channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.2 Experimental (1.2.0-experimental2)

This is the latest release of the experimental channel. It supports all experimental channel features and features from Version 1.2 Preview 1 (1.2.0-preview1).

To download, retarget your WinAppSDK NuGet version to `1.2.220909.2-experimental2`.

Fixed issue

In upcoming Windows Insider Preview builds, applications using Windows App SDK would fail to launch.

Version 1.2 Experimental (1.2.0-experimental1)

This is the latest release of the experimental channel. It supports all experimental channel features.

To download, retarget your WinAppSDK NuGet version to `1.2.220727.1-experimental1`.

Input & Composition

First introduced in Windows App SDK 0.8, there are several experimental classes in the Microsoft.UI.Input.Experimental & Microsoft.UI.Composition.Experimental namespaces.

New to this release:

- InputPointerSource has a new static factory, GetforWindowId.

Content

New to this release, the experimental classes in the Microsoft.UI.Content namespace provide the building blocks of interactive content. These are low level primitives that can be assembled into content to provide the interactive experience for an end user. The content defines the structure for: rendering output with animations, processing input on different targets, providing accessibility representation, and handling host state changes.

Notable APIs:

- `ContentIsland` - brings together Output, Input, and Accessibility and provides the abstraction for interactive content. A custom visual tree can be constructed and made interactive with these APIs.
- `DesktopChildSiteBridge` - enables a `ContentIsland` to be connected into an HWND-based hierarchy.

Check out the sample on GitHub for more information.

Dispatching

DispatcherQueue now dispatches as reentrant. Previously, no more than a single DispatcherQueueHandler callback could be active on a single thread at a time. Now, if a handler starts a nested message pump, additional callbacks dispatch as reentrant. This matches Win32 behavior around window messages and nested message pumps.

Notifications

Registering app display name and icon for app notification is now supported. Check out the spec on GitHub for additional information.

WinUI 3

- Controls and styles are up to date with the WinUI 2.8 release.
- UWP is no longer supported in the experimental releases.

Other limitations and known issues

- Apps need to be rebuilt after updating to Windows App SDK 1.2-experimental1 due to a breaking change introduced in the ABI.
- Apps that reference a package that depends on WebView2 (like Microsoft.Identity.Client) fail to build. This is caused by conflicting binaries at build time. See issue 2492 on GitHub for more information.
- Using `dotnet build` with a WinAppSDK C# class library project may see a build error "Microsoft.Build.Packaging.Pri.Tasks.ExpandPriContent task could not be loaded". To resolve this issue set `<EnableMsixTooling>true</EnableMsixTooling>` in your project file.
- The default WinAppSDK templates note that the MaxVersionTested="10.0.19041.0" when it should be "10.0.22000.0". For full support of some features, notably UnlockedDEHs, update the MaxVersionTested to "10.0.22000.0" in your project file.

Experimental channel release notes for the Windows App SDK 1.0

Article • 05/23/2024

> **ⓘ Important**
>
> The experimental channel is **not supported** for use in production environments, and apps that use the experimental releases cannot be published to the Microsoft Store.

The experimental channel provides releases of the Windows App SDK that include experimental channel features that are in early stages of development. APIs for experimental features have the Experimental attribute. If you call an experimental API in your code, you will receive a build-time warning. All APIs in the experimental channel might have breaking changes in future releases, but experimental APIs are especially subject to change. Experimental features may be removed from the next release, or may never be released.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on experimental releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest experimental channel release:

- Latest experimental channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 1.0 Experimental (1.0.0-experimental1)

This release supports all experimental channel features.

Download

The following sections describe new and updated features, limitations, and known issues for this release.

WinUI 3

This release of WinUI 3 is focused on building towards new features for 1.0 stable and fixing bugs.

- **New features**: Support for showing a ContentDialog per window rather than per thread.
- **Bugs**: For the full list of bugs addressed in this release, see our GitHub repo.
- **Samples**: To see WinUI 3 controls and features in action, you can clone and build the WinUI 3 Gallery app from GitHub, or download the app from the Microsoft Store.

For more information or to get started developing with WinUI, see:

- WinUI
- Create your first WinUI 3 (Windows App SDK) project

Push notifications (experimental feature)

This release introduces a push notifications API that can be used by packaged desktop apps with Azure app registration-based identities. To use this feature, you must sign up for our private preview.

Important limitations:

- Push notifications are only supported in MSIX packaged apps that are running on Windows 10 version 2004 (build 19041) or later releases.
- Microsoft reserves the right to disable or revoke apps from push notifications during the private preview.
- Microsoft does not guarantee the reliability or latency of push notifications.
- During the private preview, push notification volume is limited to 1 million per month.

For more information, see Push notifications overview.

Windowing

This release includes updates to the windowing APIs. These are a set of high-level windowing APIs, centered around the AppWindow class, which allows for easy-to-use

windowing scenarios that integrates well with the Windows user experience and other apps. This is similar to, but not the same as, the UWP AppWindow.

Important limitations:

- This release of `AppWindow` is currently available only to Win32 apps (both packaged and unpackaged).
- The Windows App SDK does not currently provide methods for attaching UI framework content to an `AppWindow`; you're limited to using the `HWND` interop access methods.
- The Windowing API's will currently not work on Windows version 1809 and 1903 for AMD64.

For more information, see Manage app windows (Windows App SDK).

Deployment for unpackaged apps

This release introduces updates to the *dynamic dependencies* feature, including the *bootstrapper API*.

Important limitations:

- The dynamic dependencies feature is only supported for unpackaged apps.
- Elevated callers aren't supported.

For more information, see the following articles:

- MSIX framework packages and dynamic dependencies
- Use the Windows App SDK runtime for apps packaged with external location or unpackaged

Other limitations and known issues

- **No support for Any CPU build configuration**: The Windows App SDK is written in native code and thus does not support **Any CPU** build configurations. The WinUI 3 templates in Visual Studio only allow architecture-specific builds. When adding the Windows App SDK to an existing .NET application or component that supports **Any CPU**, you must specify the desired architecture: `x86`, `x64` or `arm64`.
- **.NET apps must target build 18362 or later**: Your TFM must be set to `net6.0-windows10.0.18362` or later, and your packaging project's `<TargetPlatformVersion>` must be set to 18362 or later. For more info, see the known issue on GitHub.
- **C# apps using 1.0 Experimental must use one of the following .NET SDKs**:

- .NET 6 SDK or later (see Download .NET and .NET 5 will reach End of Support on May 10, 2022).

Experimental channel release notes for the Windows App SDK 0.8

Article • 05/23/2024

> **ⓘ Important**
>
> The experimental channel is **not supported** for use in production environments, and apps that use the experimental releases cannot be published to the Microsoft Store.

The experimental channel provides releases of the Windows App SDK that include experimental channel features that are in early stages of development. APIs for experimental features have the Experimental attribute. If you call an experimental API in your code, you will receive a build-time warning. All APIs in the experimental channel might have breaking changes in future releases, but experimental APIs are especially subject to change. Experimental features may be removed from the next release, or may never be released.

Important links:

- If you'd like to upgrade an existing app from an older version of the Windows App SDK to a newer version, see Update existing projects to the latest release of the Windows App SDK.
- For documentation on experimental releases, see Install tools for preview and experimental channels of the Windows App SDK.

Latest experimental channel release:

- Latest experimental channel release notes for the Windows App SDK

Latest stable channel release:

- Latest stable channel release notes for the Windows App SDK

Version 0.8 Preview (0.8.0-preview)

This release supports all experimental channel features.

Download

The following sections describe new and updated features, limitations, and known issues for this release.

WinUI 3

This release introduces critical bug fixes (including those fixed in 0.5 servicing releases) and other changes for WinUI. For a complete list, see the Overview and release notes: WinUI 3 - Project Reunion 0.8 Preview (May 2021).

App lifecycle (experimental feature)

This release introduces new experimental features related to managing the app lifecycle of your app.

- All apps (packaged and unpackaged) can use **GetActivatedEventArgs** (although packaged apps can already use the implementation of this in the platform).
- Only unpackaged apps can use the **RegisterForXXXActivation** functions.
- Packaged desktop apps can use app lifecycle instancing.

For more information, see App instancing with the app lifecycle API and Rich activation with the app lifecycle API.

Deployment for unpackaged apps (experimental feature)

This release introduces new experimental deployment features for unpackaged apps. Unpackaged apps can now dynamically take a dependency on the Windows App SDK runtime packages so you can continue using your existing MSI or setup program for app deployment. This is available through the following features:

- Standalone installer for Windows App SDK.
- MSIX package bundle that includes dynamic dependencies functionality.

For more info, see Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged.

DWriteCore

This release adds the following features:

- Text decorations (underline and strikethrough in the text layout API)
- Vertical text layout
- Font face kerning API

- Experimental support for unpackaged apps

For more information, see DirectWrite to DWriteCore migration.

MRT Core

This release adds the following features:

- The build action for resources is now automatically set, reducing the need for manual project configuration.
- Experimental support for unpackaged apps.

For more information, see Manage resources with MRT Core.

Limitations and known issues

- **No support for Any CPU build configuration**: The Windows App SDK is written in native code and thus does not support **Any CPU** build configurations. The WinUI 3 templates in Visual Studio only allow architecture-specific builds. When adding the Windows App SDK to an existing .NET application or component that supports **Any CPU**, you must specify the desired architecture: `x86`, `x64` or `arm64`.
- **.NET apps must target build 18362 or later**: Your TFM must be set to `net6.0-windows10.0.18362` or later, and your packaging project's `<TargetPlatformVersion>` must be set to 18362 or later. For more info, see the known issue on GitHub.

Samples

The Windows App SDK samples do not work with this release.

Breaking changes - Project Reunion 0.8 to Windows App SDK 1.0

Article • 04/19/2024

If you're migrating an app to Windows App SDK 1.0 from Project Reunion 0.8, the breaking changes listed here might affect you. Changes are grouped by technology area, such as input and MRT Core.

Input

API changes from 0.8 to 1.0

- No access to experimental types | API change |
- Stable Microsoft.UI.Input.PointerPoint added. It replaces **Microsoft.UI.Input.Experimental.ExpPointerPoint**.
  - PointerPoint now references Microsoft.UI.Input enums and structs instead of **Windows.UI.*** enums and structs (for example, IPointerPointTransform, PointerUpdateKind, PointerDeviceType).
  - PointerPoint is now fully agile.
  - PointerPoint static functions **GetCurrentPoint**, **GetCurrentPointTransformed**, **GetIntermediatePoints**, and **GetIntermediatePointsTransformed** removed. They are replaced by member functions on PointerPoint and PointerEventArgs.
  - New GetTransformedPoint method.
  - Removed **ContactRectRaw** from PointerPointProperties.
  - Removed **RawPosition** properties.
- Stable Microsoft.UI.Input.PointerEventArgs added. It replaces **Microsoft.UI.Input.Internal.ExpPointerEventArgs)**.
  - New GetIntermediateTransformedPoints method.
- Stable Microsoft.UI.Input.GestureRecognizer added. It replaces **Microsoft.UI.Input.Experimental.ExpGestureRecognizer**. References Microsoft.UI.Input enums, structs, and classes instead of **Windows.UI.Input.*** and **Windows.UI.Core.*** types (for example, GestureSettings, ManipulationDelta, TappedEventArgs).
- Public stable InputCursor, InputSystemCursor, and InputDesktopResourceCursor added. This replaces previous references to **Windows.UI.Core.CoreCursor** in the 0.8 API surface.
- Public stable InputPointerSource added – this is returned from the XAML SwapChainPanel class instead of the previous experimental

Microsoft.UI.Input.Experimental.ExpIndependentPointerInputObserver class.
    - References **Microsoft.UI.Input.InputCursor** instead of **Windows.UI.Core.CoreCursor**.
    - References **Microsoft.UI.Input** structs, enums, and types instead of **Windows.UI.*** types, such as **PointerEventArgs** and **InputPointerSourceDeviceKinds**).
    - **Type** is no longer explicitly closeable.
- **Microsoft.UI.Input.KeyboardInput** renamed to **Microsoft.UI.Input.InputKeyboardSource**.

Behavior changes from 0.8 to 1.0

- Underlying input system infrastructure upgraded to use an independent message queue for processing.
    - Supports low-latency off-UI-thread input such as inking.
    - Fully supports lifted interaction tracker APIs such as **Microsoft.UI.Composition.VisualInteractionSource** (and others).
    - Fully supports hover input for off-thread input delivery (this was a limitation in 0.8).
    - System input messages, such as **WM_POINTERDOWN**, are no longer visible through Win32 APIs on the UI thread as they are routed to an independent message queue inside the infrastructure.
- **PointerPoint** is now agile and can be accessed on any thread.
- **PointerPoint** objects can no longer be constructed statically from a pointer ID.
- XAML-based drag and drop operations fully support mouse, touch, and pen input (0.8 used pen-to-mouse downleveling).
- Direct use of **Windows.ApplicationModel.DataTransfer.DragDrop.Core.CoreDragOperation** will no longer work on the UI thread. XAML drag and drop must be used instead.

MRT Core

MRT Core APIs have moved from the Microsoft.ApplicationModel.Resources namespace to the Microsoft.Windows.ApplicationModel.Resources namespace.

Overview and release notes: WinUI 3 - Project Reunion 0.8 Preview (May 2021)

Article • 03/13/2023

WinUI 3 is a native user experience (UX) framework for building modern Windows apps. It ships independently from the Windows operating system as a part of Project Reunion (now called the **Windows App SDK**). The 0.8 Preview release provides WinUI 3 templates in Visual Studio to help you start building apps with a WinUI 3-based user interface.

WinUI 3 - Project Reunion 0.8 Preview is a pre-release version of WinUI 3 that includes bug fixes, general improvements, and experimental features - some of which will be stabilized for the Windows App SDK 0.8 stable release in June 2021.

> **ⓘ Important**
>
> This preview release is intended for early evaluation and to gather feedback from the developer community. It should **NOT** be used for production apps.
>
> If you're looking to ship a production app using Project Reunion and WinUI 3, see Overview and release notes: WinUI 3 - Project Reunion 0.5.
>
> Please use the WinUI GitHub repo to provide feedback and log suggestions and issues.

> **ⓘ Note**
>
> **Project Reunion** is the previous code name for the Windows App SDK. This documentation still uses **Project Reunion** when referring to previous releases that used this code name.

Install WinUI 3 - Project Reunion 0.8 Preview

This version of WinUI 3 is available as part of the Project Reunion 0.8 Preview. To install, see:

Install tools for preview and experimental channels of the Windows App SDK

Since WinUI ships as a part of Project Reunion, you'll download the Project Reunion Visual Studio Extension (VSIX) to get started, which includes a set of developer tools and

components. For more on the Project Reunion package, see Deploy apps that use the Windows App SDK. The Windows App SDK VSIX includes WinUI 3 templates in Visual Studio that you'll use to build your WinUI 3 app.

> **Note**
>
> To see WinUI 3 controls and features in action, you can clone and build the **WinUI 3 Controls Gallery** from GitHub, or download it from the **Microsoft Store**.

Once you've set up your development environment, see WinUI 3 templates in Visual Studio to familiarize yourself with the available Visual Studio project and item templates.

For more information about getting started with building a WinUI 3 app, see the following articles:

- Create your first WinUI 3 project
- Build a C# .NET app with WinUI 3 and Win32 interop

Aside from the limitations and known issues, building an app using the WinUI projects is similar to building a UWP app with XAML and WinUI 2. Therefore, most of the guidance documentation for UWP apps and the **Windows.UI** WinRT namespaces in the Windows SDK is applicable.

WinUI 3 API reference documentation is available here: WinUI 3 API Reference

WebView2

To use WebView2 with this WinUI 3 release, please download the Evergreen Bootstrapper or Evergreen Standalone Installer found on this page if you don't already have the WebView2 Runtime installed.

Windows Community Toolkit

If you're using the Windows Community Toolkit, download the latest version.

Visual Studio Support

In order to take advantage of the latest tooling features added into WinUI 3 like Hot Reload, Live Visual Tree, and Live Property Explorer, you must use a preview version of Visual Studio 2019 16.10. Please note that Visual Studio preview releases are pre-release products, so you may run into bugs and limitations when using preview versions of Visual Studio to build WinUI 3 apps.

The table below shows the compatibility of Visual Studio 2019 versions with WinUI 3 - Project Reunion 0.5.

Expand table

VS Version	WinUI 3 - Project Reunion 0.5
16.8	No
16.9	Yes, but with no Hot Reload, Live Visual Tree, or Live Property Explorer
16.10 Previews	Yes, with all WinUI 3 tooling (in preview)

Updating your existing WinUI 3 app

If you created an app with an earlier preview or stable version of WinUI 3, you can update the project to use WinUI 3 - Project Reunion 0.8 Preview. For instructions, see Update existing projects to the latest release of Project Reunion.

Major changes introduced in this release

- Pivot control is now available to use in this release.
- Most of the critical bug fixes from the Project Reunion v0.5.5, v0.5.6, and v0.5.7 servicing releases are included in this release as well. For servicing fixes that didn't make it into this preview, see Known Issues.

List of bugs fixed in WinUI 3 - Project Reunion 0.8 Preview

- x:Bind does not work in a custom MenuFlyoutItem (more generally, x:Bind in ControlTemplate doesn't work if the parent namescope also uses x:Bind)
  - Thanks to @lhak for filing this issue on GitHub!
- Hide windowed popups when the top-level window (or island) moves
- StandardUICommand page in WinUI 3 Controls Gallery not showing everything
- Mouse right-click in TextBox crashes the application
  - Thanks to @Herdubreid for filing this issue on GitHub!
- Context menu displayed at the wrong location for EditableComboBox

- Changing RichTextBlock Selection with touch makes selection indicator go away
- Microsoft C++ exception: winrt::hresult_error at memory location 0x... when NavigationView is being used
  - Thanks to @LeftTwixWand for filing this issue on GitHub!
- WinUI 3 error message needs rewording: "Cannot resolve 'Windows.metadata'. Please install the Windows Software Development Kit. The Windows SDK is installed with Visual Studio."
- VSM Setter quirk for raising exception has backwards logic
  - Thanks to @HppZ for filling this issue on GitHub!
- Move focus off the WebView2 (if necessary) when browser process crashes
- ProgressBar doesn't show difference between Paused and Error option
  - Thanks to @j0shuams for filing this issue on GitHub!
- PointerReplay constantly running
- NavigationView causes crash in UWP, Reunion 0.5 Preview
  - Thanks to @kalin-todorov for filing this issue on GitHub!
- AutoSuggestBox, ComboBox, and CommandBarFlyout aren't setting ShouldConstrainToRootBounds="false" on their popup
- WinUI 3 - Project Reunion 0.5 generating C++ exceptions for a C# managed app
  - Thanks to @Noemata for filing this issue on GitHub!
- WebView2 initial tab focus lost
- WebView2 crashes when DPI changes after Close()
- Change in Appearance of AppBarButton with Flyout on CommandBar in WinUI3
  - Thanks to @eleanorleffler for filing this issue on GitHub!

Features and capabilities introduced in past WinUI 3 Previews

The following features and capabilities were introduced in past WinUI 3 preview releases and continue to be supported in WinUI 3 - Project Reunion 0.8 Preview.

> **Note**

Some of the following features will continue to be a part of WinUI 3 previews, but may not be a part of the next supported release. These features are marked as experimental and will throw a warning when used in an app. APIs that are a part of the WinUI 2.6 pre-release are also marked as experimental in this release.

- Ability to create desktop apps with WinUI, including .NET for Win32 apps
- Preview-level support for building UWP apps
- RadialGradientBrush
- TabView updates
- Dark theme updates
- Improvements and updates to WebView2
  - Support for High DPI
  - Support for window resizing and moving
  - Updated to target more recent version of Edge
  - No longer necessary to reference a WebView2-specific Nuget package
- SwapChainPanel
- MRT Core Support
  - This makes apps faster and lighter on startup and provides quicker resource lookup.
- Arm64 Support
- Drag and drop inside and outside of apps
- RenderTargetBitmap (currently only XAML content - no SwapChainPanel content)
- Custom cursor support
- Off-thread input
- Improvements to our tooling/developer experience:
  - Live Visual Tree, Hot Reload, Live Property Explorer and similar tools
  - Intellisense for WinUI 3
- Improvements required for open source migration
- Custom titlebar capabilities: new Window.ExtendsContentIntoTitleBar and Window.SetTitleBar APIs that allow developers to create custom title bars in desktop apps.
- VirtualSurfaceImageSource support
- In-app acrylic
- Multi-window support in desktop apps
- Input validation

Provide feedback and suggestions

We welcome your feedback in the WinUI GitHub repo.

Limitations and known issues

The WinUI 3 - Project Reunion 0.8 Preview is just that, a preview. Please expect bugs, limitations, and other issues.

The following items are some of the known issues with WinUI 3 - Project Reunion 0.8. If you find an issue that isn't listed below, please let us know by contributing to an existing issue or filing a new issue through the WinUI GitHub repo.

Platform and OS support

WinUI 3 - Project Reunion 0.8 Preview is compatible with PCs running the Windows 10 October 2018 Update (version 1809 - build 17763) and newer.

Developer tools

- Only C# and C++/WinRT apps are supported.
- Desktop apps support .NET 6 (and later) and C# 9, and must be packaged in an MSIX app.
- No XAML Designer support.
- New C++/CX apps are not supported, however, your existing apps will continue to function (please move to C++/WinRT as soon as possible).
- Unpackaged desktop deployment is not supported.
- When running a desktop app using F5, make sure that you are running the packaging project. Hitting F5 on the app project will run an unpackaged app, which WinUI 3 does not yet support.

Missing platform features

- Xbox support
- HoloLens support
- Windowed popups
  - More specifically, the `ShouldConstrainToRootBounds` property always acts as if it's set to `true`, regardless of the property value.
- Inking support, including:
  - InkCanvas
  - HandwritingView
  - InkPresenter

- Background acrylic
- MediaElement and MediaPlayerElement
- MapControl
- SwapChainPanel does not support transparency
- AcrylicBrush and other effects using a CompositionBackdropBrush can't sample from a SwapChainPanel or WebView2.
- Global Reveal uses fallback behavior, a solid brush
- XAML Islands is not supported in this release
- Using WinUI 3 directly in an existing non-WinUI desktop app has the following limitation: The currently available path for migrating an existing app is to add a **new** WinUI 3 project to your solution, and adjust or refactor your logic as needed.
- Application.Suspending is not called in desktop apps. See API reference documentation on the Application.Suspending Event for more details.
- The UISettings.ColorValuesChanged Event and AccessibilitySettings.HighContrastChanged Event are no longer supported in desktop apps. This may cause issues if you are using it to detect changes in Windows themes.
- Previously, to get a CompositionCapabilities instance you would call CompositionCapabilites.GetForCurrentView(). However, the capabilities returned from this call were *not* dependent on the view. To address and reflect this, we've deleted the GetForCurrentView() static in this release, so now you can create a CompositionCapabilties object directly.
- CoreWindow, ApplicationView, CoreApplicationView, CoreDispatcher and their dependencies are not supported in desktop apps (see below)

CoreWindow, ApplicationView, CoreApplicationView, and CoreDispatcher in desktop apps

New in WinUI 3 Preview 4 and standard going forward, CoreWindow, ApplicationView, CoreApplicationView CoreDispatcher, and their dependencies are not available in desktop apps. For example, the Window.Dispatcher property is always **null**, but the **Window.DispatcherQueue** property can be used as an alternative.

These APIs only work in UWP apps. In past previews they've partially worked in desktop apps as well, but since Preview 4 they've been fully disabled. These APIs are designed for the UWP case where there is only one window per thread, and one of the features of WinUI 3 is to enable multiple in the future.

There are APIs that internally depend on existence of these APIs, which consequently aren't supported in a desktop app. These APIs generally have a static `GetForCurrentView` method. For example UIViewSettings.GetForCurrentView.

For more information on affected APIs as well as workarounds and replacements for these APIs, please see Windows Runtime APIs not supported in desktop apps.

Known issues

- You may receive a build error due to mismatched versions of the .NET SDK and the winrt.runtime.dll. As a workaround, you can try the following:

  Explicitly set your .NET SDK to the correct version. To determine the correct version for your app, locate the `<TargetFramework>` tag in your project file. Using the Windows SDK build number that your app is targeting in the `<TargetFramework>` tag (such as 18362 or 19041), add the following item to your project file, then save your project:

  XML

  ```
  <ItemGroup>
      <FrameworkReference Update="Microsoft.Windows.SDK.NET.Ref"
  RuntimeFrameworkVersion="10.0.{Target Windows SDK Build Number}.16" />
      <FrameworkReference Update="Microsoft.Windows.SDK.NET.Ref"
  TargetingPackVersion="10.0.{Target Windows SDK Build Number}.16" />
  </ItemGroup>
  ```

  Note this workaround is required for .NET SDK 5.0.203 and earlier, but will not be required for .NET SDK 5.0.204 or 5.0.300.

- When using Visual Studio 2019 16.10 Preview 2, Live Visual Tree may cause a crash. To avoid this, update to the latest Visual Studio 2019 16.10 Preview.

- Window caption buttons may be misplaced when SetTitleBar is not set or null

WinUI 3 Controls Gallery

Check out the WinUI 3 Controls Gallery (previously called *XAML Controls Gallery - WinUI 3 version*) for a sample app that includes all controls and features that are a part of WinUI 3 - Project Reunion 0.8 Preview.

Example of the WinUI 3 Controls Gallery app

The WinUI 3 Controls Gallery app is available through the Microsoft Store.

You can also download the sample by cloning the GitHub repo. To do this, clone the **winui3** branch using the following command:

> **Note**
>
> There's also a **winui3preview** branch in this GitHub repo that provides a version of the WinUI 3 Controls Gallery that's using WinUI 3 - Project Reunion 0.8 Preview.

```
git clone --single-branch --branch winui3 https://github.com/microsoft/Xaml-Controls-Gallery.git
```

After cloning, ensure that you switch to the **winui3** branch in your local Git environment:

```
git checkout winui3
```

Overview and release notes: WinUI 3 - Project Reunion 0.5 (March 2021)

Article • 03/13/2023

WinUI 3 is a native user experience (UX) framework for building modern Windows apps. It ships independently from the Windows operating system as a part of Project Reunion (now called the **Windows App SDK**). The Project Reunion 0.5 release provides Visual Studio project templates to help you start building apps with a WinUI 3-based user interface.

WinUI 3 - Project Reunion 0.5 is the first stable, supported version of WinUI 3 that can be used to create production apps that can be published to the Microsoft Store. This release consists of the stability updates and general improvements that allow WinUI 3 to be forward-compatible and production-ready.

> **Note**
>
> **Project Reunion** is the previous code name for the Windows App SDK. This documentation still uses **Project Reunion** when referring to previous releases that used this code name.

Install WinUI 3 - Project Reunion 0.5

This new version of WinUI 3 is available as part of Project Reunion 0.5. To install, see:

Install tools for preview and experimental channels of the Windows App SDK

Now that WinUI ships as a part of Project Reunion, you'll download the Project Reunion Visual Studio Extension (VSIX) to get started, which includes a set of developer tools and components. For more on the Project Reunion package, see Deploy apps that use the Windows App SDK. The Windows App SDK VSIX includes WinUI 3 templates in Visual Studio that you'll use to build your WinUI 3 app.

> **Note**
>
> To see WinUI 3 controls and features in action, you can clone and build the WinUI 3 version of the XAML Controls Gallery from GitHub.

Once you've set up your development environment, see WinUI 3 templates in Visual Studio to familiarize yourself with the available Visual Studio Project and Item templates.

For more information about getting started with building a WinUI 3 app, see the following articles:

- Create your first WinUI 3 project
- Build a C# .NET app with WinUI 3 and Win32 interop

Aside from the limitations and known issues, building an app using the WinUI projects is similar to building a UWP app with XAML and WinUI 2. Therefore, most of the guidance documentation for UWP apps and the **Windows.UI** WinRT namespaces in the Windows SDK is applicable.

WinUI 3 API reference documentation is available here: WinUI 3 API Reference

WebView2

To use WebView2 with this WinUI 3 release, please download the Evergreen Bootstrapper or Evergreen Standalone Installer found on this page if you don't already have the WebView2 Runtime installed.

Windows Community Toolkit

If you're using the Windows Community Toolkit, download the latest version.

Visual Studio Support

In order to take advantage of the latest tooling features added into WinUI 3 like Hot Reload, Live Visual Tree, and Live Property Explorer, you must use a preview version of Visual Studio 2019 16.10. Please note that Visual Studio preview releases are pre-release products, so you may run into bugs and limitations when using preview versions of Visual Studio to build WinUI 3 apps.

The table below shows the compatibility of Visual Studio 2019 versions with WinUI 3 - Project Reunion 0.5.

Expand table

VS Version	WinUI 3 - Project Reunion 0.5
16.8	No

VS Version	WinUI 3 - Project Reunion 0.5
16.9	Yes, but with no Hot Reload, Live Visual Tree, or Live Property Explorer
16.10 Previews	Yes, with all WinUI 3 tooling (in preview)

Update your existing WinUI 3 app

If you created an app with an earlier preview or release version of WinUI 3, you can update the project to use the latest release of WinUI 3 - Project Reunion 0.5. For instructions, see Update existing projects to the latest release of the Windows App SDK.

Major changes introduced in this release

Stable features

This release provides the stability and support to make WinUI 3 suitable for production apps that can ship to the Microsoft Store. It includes support and forward compatibility for most features introduced in past previews:

- Ability to create desktop apps with WinUI, including .NET for Win32 apps
- RadialGradientBrush
- TabView updates
- Dark theme updates
- Improvements and updates to WebView2
  - Support for High DPI
  - Support for window resizing and moving
  - Updated to target more recent version of Edge
  - No longer necessary to reference a WebView2-specific Nuget package
- SwapChainPanel
- MRT Core Support
  - This makes apps faster and lighter on startup and provides quicker resource lookup.
- Arm64 Support
- Drag and drop inside and outside of apps
- RenderTargetBitmap (currently only XAML content - no SwapChainPanel content)
- Custom cursor support
- Off-thread input
- Improvements to our tooling/developer experience:
  - Live Visual Tree, Hot Reload, Live Property Explorer and similar tools

    - Intellisense for WinUI 3
- Improvements required for open source migration
- Custom titlebar capabilities: new Window.ExtendsContentIntoTitleBar and Window.SetTitleBar APIs that allow developers to create custom title bars in desktop apps.
- VirtualSurfaceImageSource support
- In-app acrylic

Preview features

As this is a stable release of WinUI 3, preview features have been removed. You can still access preview features by using the latest preview version of WinUI 3 (see WinUI 3 - Project Reunion 0.8 Preview). Please note the following key features are still in preview, and work to stabilize them is ongoing:

- UWP support
    - This means you cannot build or run a UWP app using the WinUI 3 - Project Reunion 0.5 VSIX. You'll need to use the WinUI 3 - Project Reunion Preview VSIX, and follow the rest of the instructions in Create your first WinUI 3 project. See Overview and release notes: WinUI 3 - Project Reunion 0.8 Preview for more information.
- Multi-window support in desktop apps
- Input validation

Provide feedback and suggestions

We welcome your feedback in the WinUI GitHub repo.

Limitations and known issues

The following items are some of the known issues with WinUI 3 - Project Reunion 0.5. If you find an issue that isn't listed below, please let us know by contributing to an existing issue or filing a new issue through the WinUI GitHub repo.

Platform and OS support

WinUI 3 - Project Reunion 0.5 is compatible with PCs running the Windows 10 October 2018 Update (version 1809 - build 17763) and newer.

Developer tools

- Only C# and C++/WinRT apps are supported
- Desktop apps support .NET 6 (and later) and C# 9, and must be packaged in an MSIX app
- No XAML Designer support
- New C++/CX apps are not supported, however, your existing apps will continue to function (please move to C++/WinRT as soon as possible)
- Unpackaged desktop deployment is not supported
- When running a desktop app using F5, make sure that you are running the packaging project. Hitting F5 on the app project will run an unpackaged app, which WinUI 3 does not yet support.

Missing Platform Features

- Xbox support
- HoloLens support
- Windowed popups
  - More specifically, the `ShouldConstrainToRootBounds` property always acts as if it's set to `true`, regardless of the property value.
- Inking support, including:
  - InkCanvas
  - HandwritingView
  - InkPresenter
- Background acrylic
- MediaElement and MediaPlayerElement
- MapControl
- SwapChainPanel does not support transparency
- AcrylicBrush and other effects using a CompositionBackdropBrush can’t sample from a SwapChainPanel or WebView2.
- Global Reveal uses fallback behavior, a solid brush
- XAML Islands is not supported in this release
- Using WinUI 3 directly in an existing non-WinUI desktop app has the following limitation: The currently available path for migrating an existing app is to add a

new WinUI 3 project to your solution, and adjust or refactor your logic as needed.

- Application.Suspending is not called in desktop apps. See API reference documentation on the Application.Suspending Event for more details.

- CoreWindow, ApplicationView, CoreApplicationView, CoreDispatcher and their dependencies are not supported in desktop apps (see below)

CoreWindow, ApplicationView, CoreApplicationView, and CoreDispatcher in desktop apps

New in WinUI 3 Preview 4 and standard going forward, CoreWindow, ApplicationView, CoreApplicationView CoreDispatcher, and their dependencies are not available in desktop apps. For example, the Window.Dispatcher property is always **null**, but the **Window.DispatcherQueue** property can be used as an alternative.

These APIs only work in UWP apps. In past previews they've partially worked in desktop apps as well, but since Preview 4 they've been fully disabled. These APIs are designed for the UWP case where there is only one window per thread, and one of the features of WinUI 3 is to enable multiple in the future.

There are APIs that internally depend on existence of these APIs, which consequently aren't supported in a desktop app. These APIs generally have a static `GetForCurrentView` method. For example UIViewSettings.GetForCurrentView.

For more information on affected APIs as well as workarounds and replacements for these APIs, please see WinRT API changes for desktop apps

Known issues

- The UISettings.ColorValuesChanged Event and AccessibilitySettings.HighContrastChanged Event are no longer supported in desktop apps. This may cause issues if you are using it to detect changes in Windows themes.

- Previously, to get a CompositionCapabilities instance you would call CompositionCapabilites.GetForCurrentView(). However, the capabilities returned from this call were *not* dependent on the view. To address and reflect this, we've deleted the GetForCurrentView() static in this release, so now you can create a CompositionCapabilties object directly.

- You may receive a build error due to mismatched versions of the .NET SDK and the winrt.runtime.dll. As a workaround, you can try the following:

Explicitly set your .NET SDK to the correct version. To determine the correct version for your app, locate the `<TargetFramework>` tag in your project file. Using the Windows SDK build number that your app is targeting in the `<TargetFramework>` tag (such as 18362 or 19041), add the following item to your project file, then save your project:

XML

```
<ItemGroup>
    <FrameworkReference Update="Microsoft.Windows.SDK.NET.Ref"
RuntimeFrameworkVersion="10.0.{Target Windows SDK Build Number}.16" />
    <FrameworkReference Update="Microsoft.Windows.SDK.NET.Ref"
TargetingPackVersion="10.0.{Target Windows SDK Build Number}.16" />
</ItemGroup>
```

Note this workaround is required for .NET SDK 5.0.203 and earlier, but will not be required for .NET SDK 5.0.204 or 5.0.300.

- When using Visual Studio 2019 16.10 Preview 2, Live Visual Tree may cause a crash. To avoid this, update to the latest Visual Studio 2019 16.10 Preview.

WinUI 3 Controls Gallery

Check out the WinUI 3 Controls Gallery (previously called *XAML Controls Gallery - WinUI 3 version*) for a sample app that includes all controls and features that are a part of WinUI 3 - Project Reunion 0.5.

Example of the WinUI 3 Controls Gallery app

You can download the sample by cloning the GitHub repo. To do this, clone the **winui3** branch using the following command:

```dos
git clone --single-branch --branch winui3 https://github.com/microsoft/Xaml-Controls-Gallery.git
```

After cloning, ensure that you switch to the **winui3** branch in your local Git environment:

```dos
git checkout winui3
```

WinUI 3 - Project Reunion 0.5 Preview (March 2021) release notes

Article • 03/13/2023

WinUI 3 is a native user experience (UX) platform for building modern Windows apps. This preview of WinUI 3 works with both desktop/Win32 and UWP apps, and includes Visual Studio project templates to help get started building apps with a WinUI-based user interface as well as a NuGet package that contains the WinUI libraries.

WinUI 3 - Project Reunion 0.5 Preview is the first release of WinUI 3 where it is provided as a part of the Project Reunion package (now called the **Windows App SDK**). Alongside that change, this preview release contains critical bug fixes, increased stability, and a few other general improvements (see **Capabilities introduced in WinUI 3 - Project Reunion 0.5 Preview**).

> **ⓘ Important**
>
> This WinUI 3 preview is intended for early evaluation and to gather feedback from the developer community. It should **NOT** be used for production apps.
>
> Please use the **WinUI GitHub repo** to provide feedback and log suggestions and issues.

> **ⓘ Note**
>
> **Project Reunion** is the previous code name for the Windows App SDK. This documentation still uses **Project Reunion** when referring to previous releases that used this code name.

Install WinUI 3 - Project Reunion 0.5 Preview

This version of WinUI 3 is available as part of the Project Reunion 0.5 Preview.

To install, follow the directions found in Install tools for preview and experimental channels of the Windows App SDK.

In contrast to past preview versions of WinUI 3, you'll download a Project Reunion VSIX package instead of a WinUI VSIX package. The Project Reunion VSIX includes WinUI 3 templates in Visual Studio that you'll use to build your WinUI 3 app. Once you've

completed your installation, the experience of developing a WinUI 3 app should not change.

> **Note**
>
> You can also clone and build the WinUI 3 Preview version of the XAML Controls Gallery.

> **Note**
>
> To use WinUI 3 tooling such as Live Visual Tree, Hot Reload, and Live Property Explorer, you must enable WinUI 3 tooling with Visual Studio Preview Features as described in the instructions here.

Once you've set up your development environment, see WinUI 3 templates in Visual Studio to familiarize yourself with the available Visual Studio Project and Item templates.

For more information about getting started with the WinUI project templates, see the following articles:

- Create your first WinUI 3 project

Aside from the limitations and known issues, building an app using the WinUI projects is similar to building a UWP app with XAML and WinUI 2. Therefore, most of the guidance documentation for UWP apps and the **Windows.UI** WinRT namespaces in the Windows SDK is applicable.

WinUI 3 API reference documentation is available here: WinUI 3 API Reference

If you created a project using WinUI 3 Preview 4, you can upgrade your project to use Project Reunion 0.5 Preview.

WebView2

To use WebView2 with this WinUI 3 preview, please download the Evergreen Bootstrapper or Evergreen Standalone Installer found on this page if you don't already have the WebView2 Runtime installed.

Windows Community Toolkit

If you're using the Windows Community Toolkit, download the latest version.

Visual Studio Support

In order to take advantage of the latest tooling features added into WinUI 3 like Hot Reload, Live Visual Tree, and Live Property Explorer, you must use the latest **preview** version of Visual Studio with the latest WinUI 3 preview and be sure to enable WinUI tooling in Visual Studio Preview Features, as described in the instructions here. The table below shows the compatibility of future versions with WinUI 3 - Project Reunion 0.5 Preview:

Expand table

VS Version	WinUI 3 - Project Reunion 0.5 Preview
16.8 RTM	No
16.9 Previews	Yes, with tooling
16.9 RTM	Yes, but no Hot Reload, Live Visual Tree, or Live Property Explorer
16.10 Previews	Yes, with tooling

Major changes introduced in this release

- WinUI 3 now ships as a part of the Project Reunion package, which will also be the mechanism for how our future supported releases will ship.
- In-app acrylic is now supported.
- The Pivot control is no longer supported, and has been deprecated in WinUI 3. We recommend using the NavigationView control for your in-app navigation scenarios.
- WinUI 3 and Project Reunion will only be supported down-level to Windows 10 version 1809 - it requires build 17763 or later.
- Preview features are now marked as experimental.
  - A preview feature is anything that will continue to be a part of WinUI 3 previews, but will not be a part of the next WinUI 3 supported release.
  - Preview features also include any experimental APIs that are a part of the WinUI 2.6 preview.
  - When building an app that uses a preview feature, your app will throw a warning.

List of bugs fixed in WinUI 3 - Project Reunion 0.5 Preview

Below is a list of user-facing bugs that the team has fixed since Preview 3. There has also been a lot of work going on surrounding stabilization and improving our testing.

- WinUI 3 error message needs rewording: "Cannot resolve 'Windows.metadata'. Please install the Windows Software Development Kit. The Windows SDK is installed with Visual Studio."
- App does not respond to theme changes in Windows when selecting Windows Default theme until restarted
- Exception on XamlDirect.CreateInstance call
  - Thanks to @BorzillaR for filing this issue on GitHub!
- ProgressBar doesn't show difference between Paused and Error option
- StandardUICommand list view item flyout shows in wrong position.
- Crash in desktop XamlControlsGallery when trying to reorder ListView items with touch
  - Thanks to @j0shuams for filing this issue on GitHub!
- Press and hold on RichTextBlock puts flyout in wrong place
- Left/Right arrows aren't moving focus through RadioButtons
  - Thanks to @vmadurga for filing this issue on Github!
- Narrator remains silent when user hits the down/up arrow keys to select the next/previous month/year/date in DatePicker
- NavigationView light-dismiss doesn't work in WinUI 3

New features and capabilities introduced in past WinUI 3 Previews

The following features and capabilities were introduced in WinUI 3 Previews 1-4 and continue to be supported in WinUI 3 - Project Reunion 0.5 Preview.

- Ability to create desktop apps with WinUI, including .NET for Win32 apps
- RadialGradientBrush
- TabView updates

- Dark theme updates
- Improvements and updates to WebView2
  - Support for High DPI
  - Support for window resizing and moving
  - Updated to target more recent version of Edge
  - No longer necessary to reference a WebView2-specific Nuget package
- SwapChainPanel
- MRT Core Support
  - This makes apps faster and lighter on startup and provides quicker resource lookup.
- Arm64 Support
- Drag and drop inside and outside of apps
- RenderTargetBitmap (currently only XAML content - no SwapChainPanel content)
- Custom cursor support
- Off-thread input
- Improvements to our tooling/developer experience:
  - Live Visual Tree, Hot Reload, Live Property Explorer and similar tools
  - Intellisense for WinUI 3
- Improvements required for open source migration
- Custom titlebar capabilities: new Window.ExtendsContentIntoTitleBar and Window.SetTitleBar APIs that allow developers to create custom title bars in desktop apps.
- VirtualSurfaceImageSource support

Provide feedback and suggestions

We welcome your feedback in the WinUI GitHub repo.

Limitations and known issues

The WinUI 3 - Project Reunion 0.5 Preview is just that, a preview. The scenarios around desktop apps are especially new. Please expect bugs, limitations, and other issues.

The following items are some of the known issues with WinUI 3 - Project Reunion 0.5 Preview. If you find an issue that isn't listed below, please let us know by contributing to an existing issue or filing a new issue through the WinUI GitHub repo.

Platform and OS support

WinUI 3 - Project Reunion 0.5 Preview is compatible with PCs running the Windows 10 October 2018 Update (version 1809 - build 17763) and newer.

Developer tools

- Only C# and C++/WinRT apps are supported
- Desktop apps support .NET 6 (and later) and C# 9, and must be packaged in an MSIX app
- UWP apps support .NET Native and C# 7.3
- Developer tools and Intellisense may not work properly in Visual Studio.
- No XAML Designer support
- New C++/CX apps are not supported, however, your existing apps will continue to function (please move to C++/WinRT as soon as possible)
- Support for multiple windows in desktop apps is in progress, but not yet complete and stable.
  - Please file a bug on our repo if you find new issues or regressions with multi-window behavior.
- Unpackaged desktop deployment is not supported
- When running a desktop app using F5, make sure that you are running the packaging project. Hitting F5 on the app project will run an unpackaged app, which WinUI 3 does not yet support.

Missing Platform Features

- Xbox support
- HoloLens support
- Windowed popups
  - More specifically, the `ShouldConstrainToRootBounds` property always acts as if it's set to `true`, regardless of the property value.
- Inking support
- Acrylic
- MediaElement and MediaPlayerElement
- MapControl
- RenderTargetBitmap for SwapChainPanel and non-XAML content
- SwapChainPanel does not support transparency
- Global Reveal uses fallback behavior, a solid brush
- XAML Islands is not supported in this release
- 3rd party ecosystem libraries will not fully function
- IMEs do not work

- CoreWindow, ApplicationView, CoreApplicationView, CoreDispatcher and their dependencies are not supported in desktop apps (see below)

CoreWindow, ApplicationView, CoreApplicationView, and CoreDispatcher in desktop apps

New in Preview 4 and standard going forward, CoreWindow, ApplicationView, CoreApplicationView CoreDispatcher, and their dependencies are not available in desktop apps. For example the Window.Dispatcher property is always null, but the Window.DispatcherQueue property can be used as an alternative.

These APIs only work in UWP apps. In past previews they've partially worked in desktop apps as well, but in Preview4 they've been fully disabled. These APIs are designed for the UWP case where there is only one window per thread, and one of the features of WinUI3 is to enable multiple.

There are APIs that internally depend on existence of these APIs, which consequently aren't supported in a desktop app. These APIs generally have a static `GetForCurrentView` method. For example UIViewSettings.GetForCurrentView.

For more information on affected APIs as well as workarounds and replacements for these APIs, please see WinRT API changes for desktop apps

Known issues

- There's an issue that's causing UWP apps to fail to launch on Windows 10 version 1809. The team is actively working on fixing this bug for the next preview release.
- Alt+F4 does not close desktop app windows.
- The UISettings.ColorValuesChanged Event and AccessibilitySettings.HighContrastChanged Event are no longer supported in desktop apps. This may cause issues if you are using it to detect changes in Windows themes.
- This release includes some experimental APIs, which will throw build warnings when used. These have not been thoroughly tested by the team and may have unknown issues. Please file a bug on our repo if you encounter any issues.
- Previously, to get a CompositionCapabilities instance you would call CompositionCapabilites.GetForCurrentView(). However, the capabilities returned from this call were *not* dependent on the view. To address and reflect this, we've

deleted the GetForCurrentView() static in this release, so now you can create a CompositionCapabilties object directly.

- For C# UWP apps:

  The WinUI 3 framework is a set of WinRT components which can be used from C++ (using C++/WinRT) or C#. When using C#, there are two versions of .NET, depending on the app model: when using WinUI 3 in a UWP app, you're using .NET Native; when using in a desktop app, you're using .NET 6 or later (and C#/WinRT).

  When using C# for a WinUI 3 app in UWP, there are a few API namespace differences compared to C# in a WinUI 3 desktop app or a C# WinUI 2 app: some types are in a `Microsoft` namespace rather than a `System` namespace. For example, rather than the `INotifyPropertyChanged` interface being in the `System.ComponentModel` namespace, it's in the `Microsoft.UI.Xaml.Data` namespace.

  This applies to:
  - `INotifyPropertyChanged` (and related types)
  - `INotifyCollectionChanged`
  - `ICommand`

  The `System` namespace versions still exist, but cannot be used with WinUI 3. This means that `ObservableCollection` doesn't work as-is in WinUI 3 C# UWP apps. For a workaround, see the CollectionsInterop sample in the XAML Controls Gallery sample.

XAML Controls Gallery (WinUI 3 Preview branch)

See the WinUI 3 Preview branch of the XAML Controls Gallery for a sample app that includes all controls and features that are a part of the WinUI 3 - Project Reunion 0.5 Preview.

Example of the WinUI 3 Preview XAML Controls Gallery app

To download the sample, clone the **winui3preview** branch using the following command:

```
git clone --single-branch --branch winui3preview
https://github.com/microsoft/Xaml-Controls-Gallery.git
```

After cloning, ensure that you switch to the **winui3preview** branch in your local Git environment:

```
git checkout winui3preview
```

System requirements for Windows app development

Article • 03/16/2023

To develop apps for Windows 10 and 11, you'll need *Visual Studio*, the *Windows SDK*, and the *Windows App SDK*. Before installing these tools, make sure your development computer meets the minimum system requirements.

Install the tools for the Windows App SDK to get started.

Visual Studio

Visual Studio is a comprehensive *Integrated Development Environment (IDE)* that's used to *edit*, *debug*, *build*, and *publish* apps.

For the minimum system requirements, see:

- Visual Studio 2022 system requirements
- Visual Studio 2019 system requirements

Windows SDK

The Windows SDK provides access to all of the APIs and development features exposed by the Windows OS. The Windows SDK is required for building Windows apps as well as other types of components (such as services and drivers). The latest Windows SDK is installed with *Visual Studio 2019* and *Visual Studio 2022* by default.

For the minimum system requirements, see Windows SDK.

Windows App SDK

The Windows App SDK is a set of developer tools that represent the next evolution in the Windows app development platform. It provides a unified set of APIs and tools that can be used in a consistent way by any desktop app on Windows 11 (and it's backward-compatible for Windows 10, version 1809).

> **Note**

The Windows App SDK was previously known by the code name *Project Reunion*. Some SDK assets (such as the VSIX extension and certain NuGet packages) still use this name, but these assets will be renamed in a future release. Some documentation still uses *Project Reunion* when referring to an existing asset or a specified earlier release.

The Windows App SDK has the following minimum system requirements:

- Windows 10, version 1809 (build 17763) or later.
- Visual Studio 2022, version 17.0 or later, with the required workloads and components.
- Visual Studio 2019, version 16.9 or later, with the required workloads and components.
- Windows SDK, version 2004 (build 19041) or later (included with Visual Studio 2019 and 2022 by default).
- If you plan to build .NET apps, you'll also need .NET 6 or later (see Download .NET).

Visual Studio support for WinUI 3 tools

You can build, run, and deploy apps built with stable versions of the Windows App SDK on Visual Studio 2019 versions *16.9*, *16.10*, and *16.11 Preview*. You can also use Visual Studio 2022 *17.0 Preview 2 and later* to build apps with the Windows App SDK *v0.8.2 and later*. However, in order to take advantage of the latest WinUI 3 tooling features such as *hot reload*, *live visual tree*, and *live property explorer*, you'll need the version of Visual Studio 2019 with a stable version of the Windows App SDK as shown in the following table:

Expand table

	Visual Studio 2019 16.9	**Visual Studio 2019 16.10**	**Visual Studio 2019 16.11 Preview**	**Visual Studio 2022 17.0 Preview**
Windows App SDK 0.5	Tools unavailable	Tools available	Tools unavailable	Tools unavailable
Windows App SDK 0.8	Tools unavailable	Tools unavailable	Tools available (starting with Visual Studio 2019 16.11 Preview).	Tools available (starting with Visual Studio 2022 17.0 Preview 2). *Requires Windows App SDK v0.8.2 or later.*

	Visual Studio 2019 16.9	Visual Studio 2019 16.10	Visual Studio 2019 16.11 Preview	Visual Studio 2022 17.0 Preview
Windows App SDK 1.0 Experimental	Tools unavailable	Tools unavailable	Tools available (starting with Visual Studio 2019 16.11 Preview 3).	Tools available (starting with Visual Studio 2022 17.0 Preview 2).
Windows App SDK 1.0 Preview 2	Tools unavailable	Tools unavailable	Tools available (starting with Visual Studio 2019 16.11 Preview 3).	Tools available (starting with Visual Studio 2022 17.0 Preview 2).

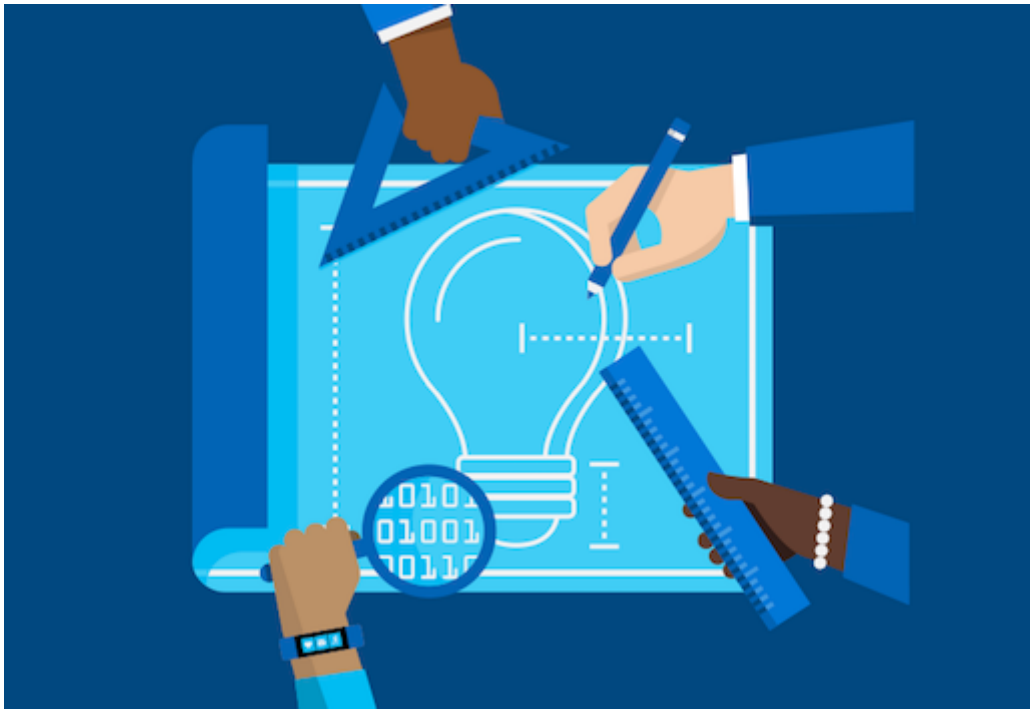
Enable your device for development

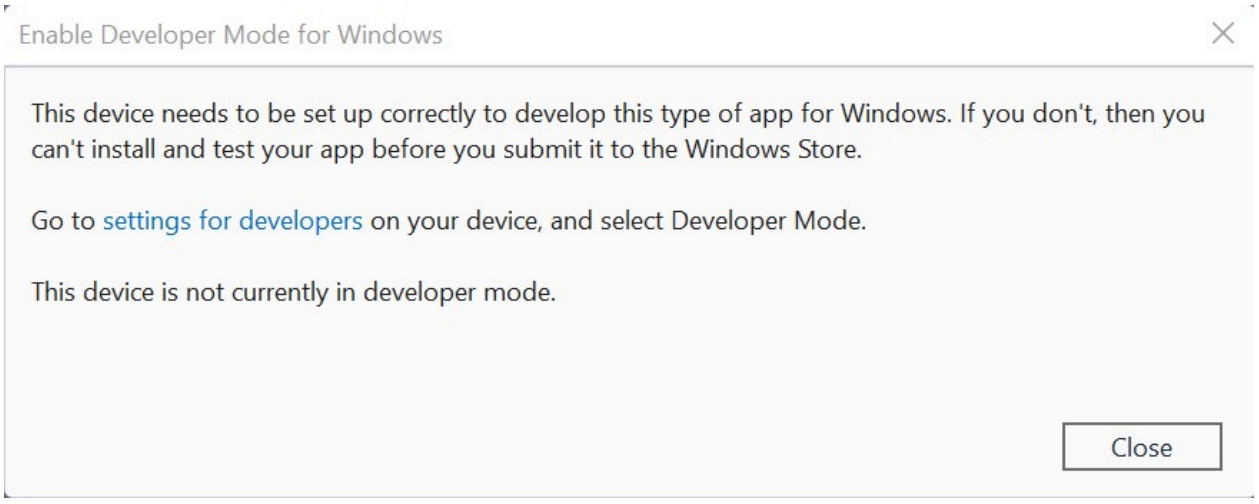
Article • 01/16/2025



If you're writing software with Visual Studio, you *will* need to enable Developer Mode on both the development PC and on any devices you'll use to test your code.

> **Note**
>
> If you're using your computer for ordinary day-to-day activities (such as gaming, web browsing, email, or Office apps), there is no need to activate Developer Mode. If you're trying to fix an issue with your computer, check out Windows help.

Opening a Windows project when Developer Mode *isn't* enabled will either open the **For developers** settings page, or cause the following dialog to appear in Visual Studio:



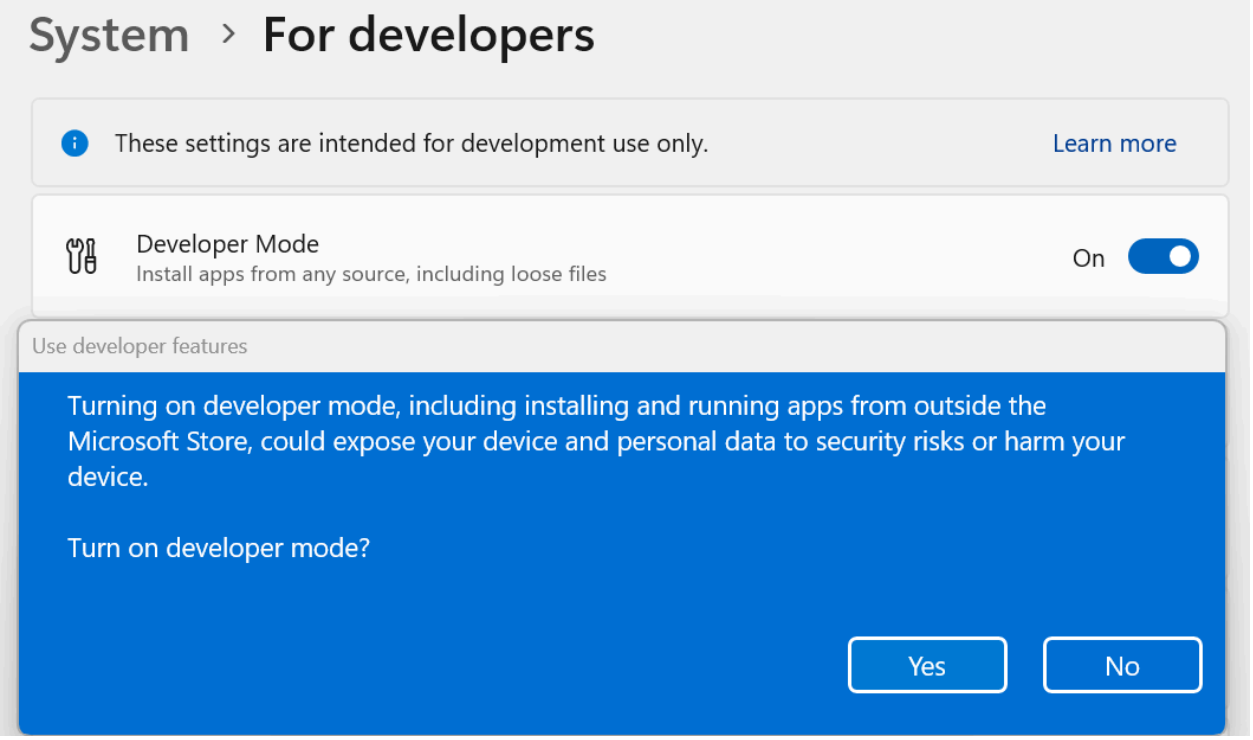
If you see this dialog, select **settings for developers** to open the **For developers** settings page.

> **Note**
>
> You can go to the **For developers** settings page at any time to *enable* or *disable* Developer Mode. Simply enter *for developers* into the search box in the taskbar.

Activate Developer Mode

To enable Developer Mode, or access other settings:

1. Open Windows Settings.
2. Search for **Developer settings** or Go to **Update & Settings** then **For developers**.
3. Toggle the Developer Mode setting, at the top of the **For developers** page
4. Read the disclaimer for the setting you choose. Click **Yes** to accept the change.



> **Note**
>
> Enabling Developer mode requires administrator access. If your device is owned by an organization, this option may be disabled.

Developer Mode features

Developer Mode replaces the requirements for a developer license. In addition to sideloading, the Developer Mode setting enables debugging and additional deployment options. This includes starting an SSH service to allow deployment to this device. In order to stop this service, you need to disable Developer Mode.

When you enable Developer Mode on desktop, a package of features is installed, including:

- **Windows Device Portal**: Device Portal is only enabled (and firewall rules are only configured for it) when the **Enable Device Portal** option is turned on.
- Installs and configures firewall rules for SSH services that allow remote installation of apps. Enabling **Device Discovery** will turn on the SSH server.

For more information on these features (or if you encounter difficulties in the installation process) check out Developer Mode features and debugging.

Developer Mode features and debugging

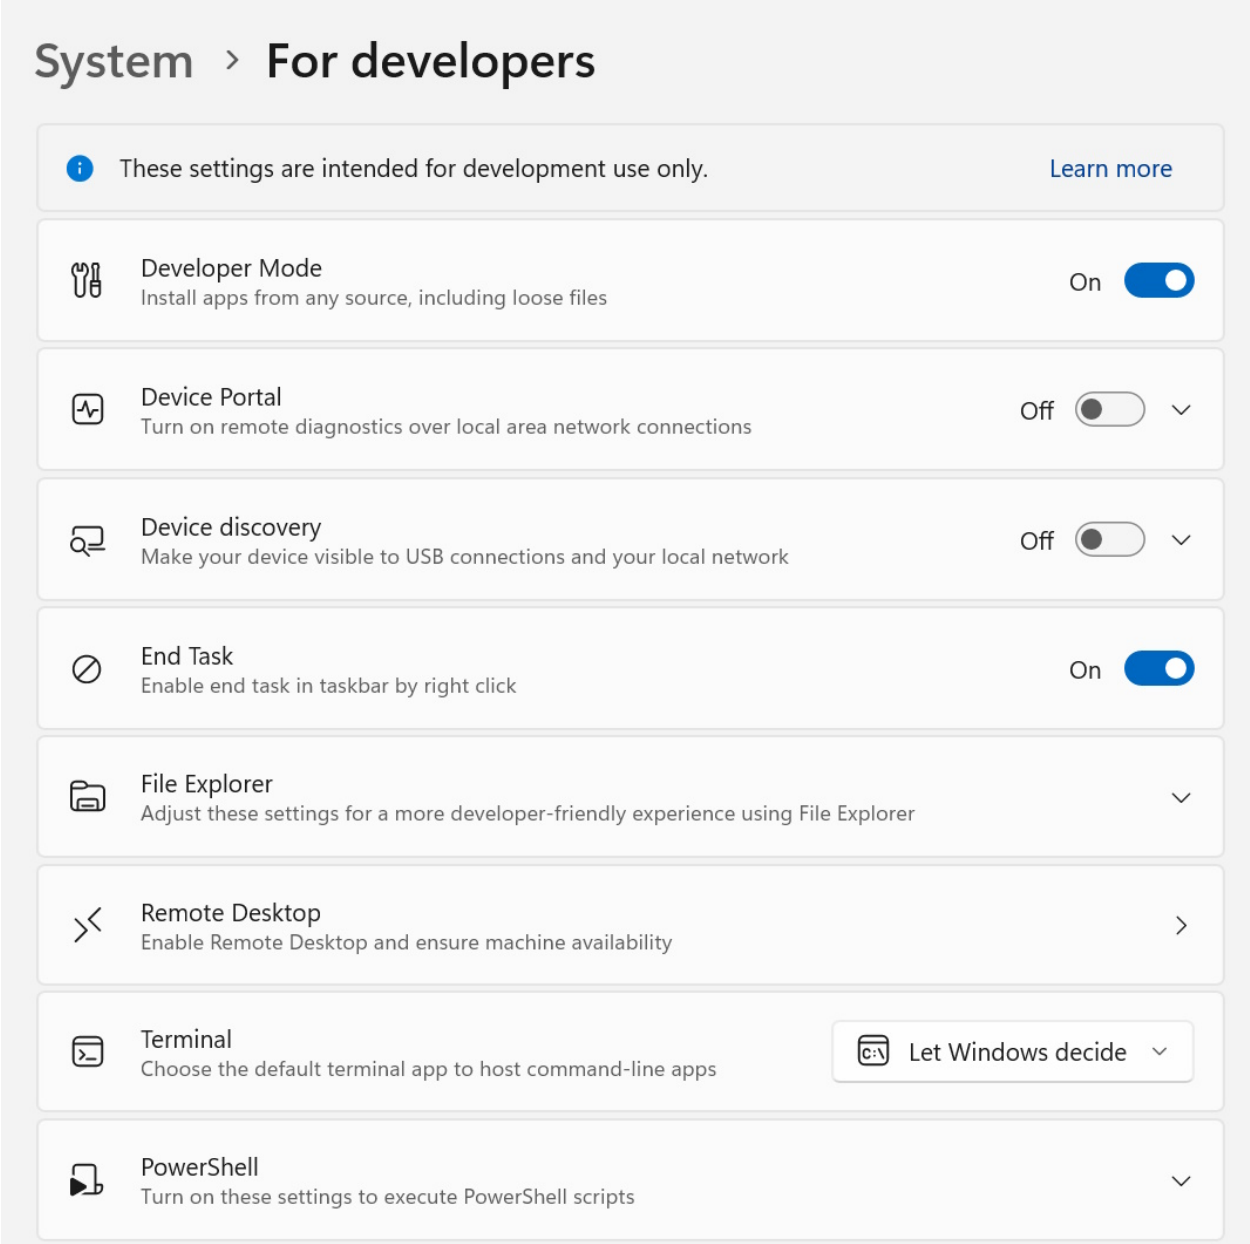
Article • 02/20/2024

If you're only interested in the basics of installing Developer Mode on your app, follow the instructions outlined in enable your device for development to get started. This article covers advanced features of Developer Mode, Developer Mode in previous versions of Windows 10, and debugging failures related to Developer Mode installations.

Additional Developer Mode features

For each device family, additional developer features may be available. These features are only available when Developer Mode is enabled on the device (and may vary depending on the version of your OS).

This image shows developer features for Windows:



Device Portal

To learn more about Device Portal, see Windows Device Portal overview.

For device-specific setup instructions, see:

- Device Portal for desktop
- Device Portal for HoloLens
- Device Portal for IoT
- Device Portal for Mobile
- Device Portal for Xbox

If you encounter problems enabling Developer Mode or Device Portal, see the Known Issues forum to find workarounds for these issues, or visit Failure to install the Developer Mode package to learn which WSUS KBs to allow in order to unblock the Developer Mode package.

SSH

SSH services are enabled when you enable Device Discovery on your device. This is used when your device is a remote deployment target for MSIX packaged applications. The names of the services are *SSH Server Broker* and *SSH Server Proxy*.

> **Note**
>
> This is not Microsoft's OpenSSH implementation, which you can find on **GitHub**.

In order to take advantage of the SSH services, you can enable Device Discovery to allow pin pairing. If you intend to run another SSH service, you can set this up on a different port or turn off the Developer Mode SSH services. To turn off the SSH services, turn off Device Discovery.

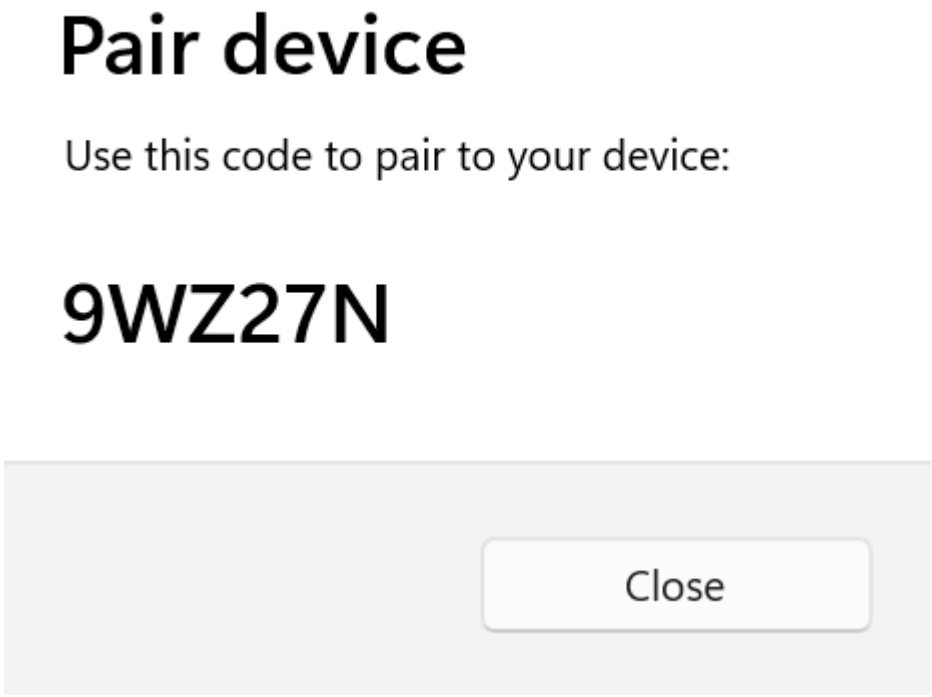
SSH login is done via the *DevToolsUser* account, which accepts a password for authentication. This password is the PIN displayed on the device after pressing the Device Discovery **Pair** button, and it's only valid while the PIN is displayed. A SFTP subsystem is also enabled for manual management of the `DevelopmentFiles` folder where loose file deployments are installed from Visual Studio.

Caveats for SSH usage

The existing SSH server used in Windows is not yet protocol compliant. Using an SFTP or SSH client may require special configuration. In particular, the SFTP subsystem runs at version 3 or less, so any connecting client should be configured to expect an old server. The SSH server on older devices uses `ssh-dss` for public key authentication (which OpenSSH has deprecated). To connect to such devices, the SSH client must be manually configured to accept `ssh-dss`.

Device Discovery

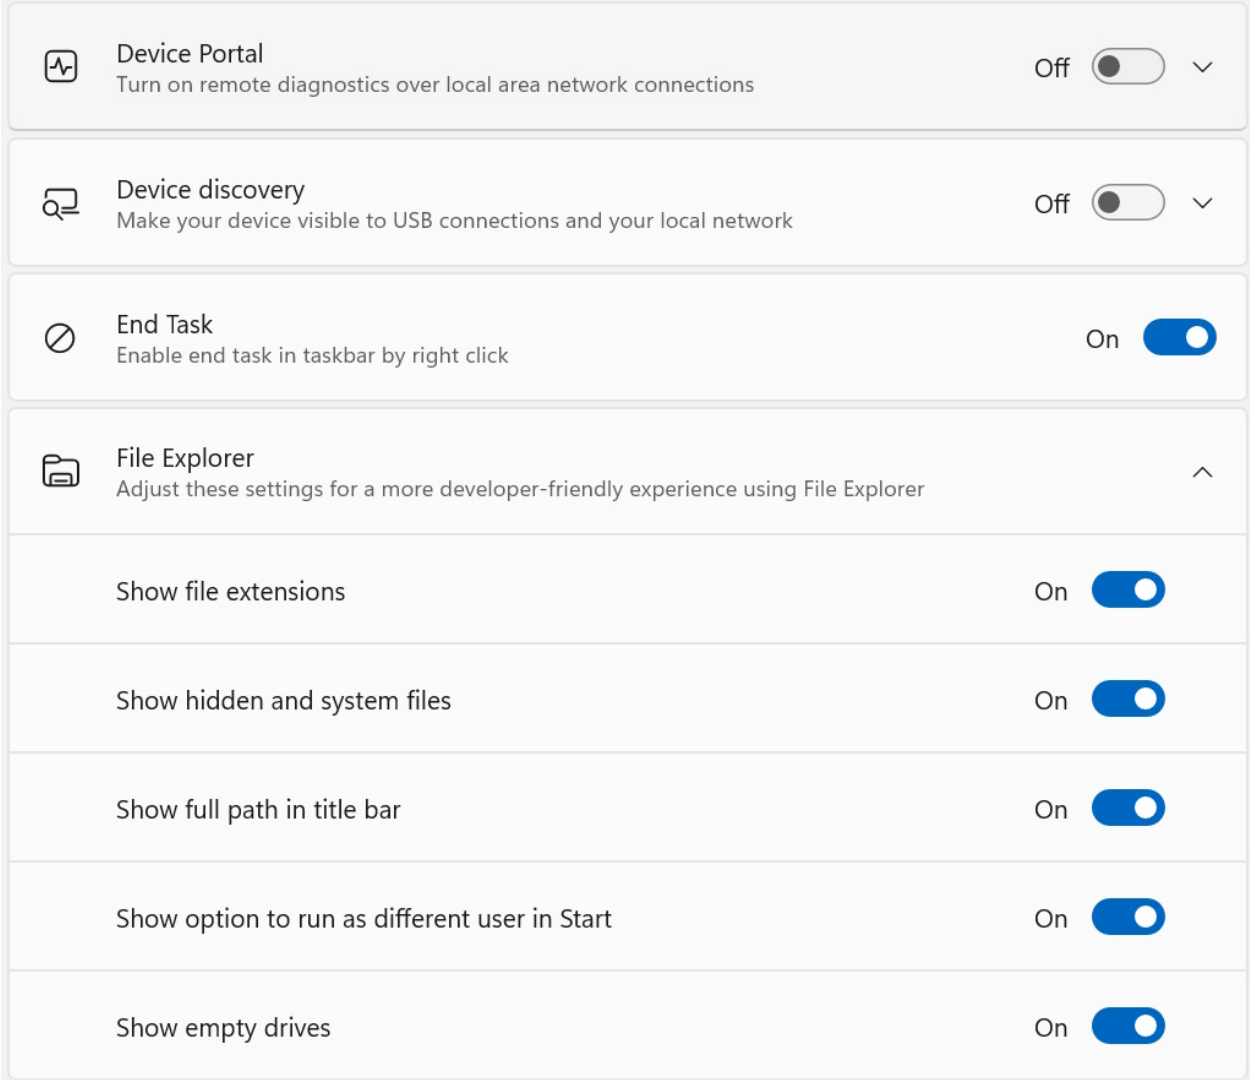
When you enable Device Discovery, you're allowing your device to be visible to other devices on the network through mDNS. This feature also allows you to get the SSH PIN for pairing to the device by pressing the **Pair** button exposed immediately after Device Discovery is enabled. This PIN prompt must be displayed on the screen in order to complete your first Visual Studio deployment targeting the device.



You should enable Device Discovery only if you intend to make the device a deployment target. For example, if you use Device Portal to deploy an app to a phone for testing, you need to enable Device Discovery on the phone, but not on your development PC.

Optimizations for Windows Explorer, Remote Desktop, and PowerShell (desktop only)

On the desktop device family, the **For developers** settings page has shortcuts to settings you can use to optimize your PC for development tasks. The sliders let you enable or disable settings easily from this single location.



Notes

In early versions of Windows 10 Mobile, a **Crash Dumps** option was present in the **Developer Settings** menu. This has been moved to Device Portal so that it can be used remotely rather than exclusively on USB.

There are several tools you can use to deploy an app from a Windows 10 PC to a Windows 10 device. Both devices must be connected to the same subnet of the network (by a wired or wireless connection) or they must be connected by USB. Both of these options only install the app package (`.appx` or `.appxbundle`). They don't install certificates.

- Use the Windows Application Deployment (`WinAppDeployCmd`) tool. Learn more about the WinAppDeployCmd tool.
- You can use Device Portal to deploy from your browser to a mobile device running Windows 10, Version 1511 or later. Use the Apps page in Device Portal to upload an app package (`.appx`) and install it on the device.

Failure to install Developer Mode package

Sometimes, due to network or administrative issues, Developer Mode won't install correctly. The Developer Mode package is required for remote deployment to this PC (using Device Portal from a browser or Device Discovery to enable SSH), but not for local development. Even if you encounter these issues, you can still deploy your app locally using Visual Studio (or from this device to another device).

See the Known Issues forum to find workarounds for these issues (and others).

> **Note**
>
> If Developer Mode doesn't install correctly, we encourage you to file a feedback request.
>
> 1. Install the **Feedback Hub app** (if you don't already have it) and open it.
> 2. Click **Add new feedback**.
> 3. Choose the **Developer Platform** category and the **Developer Mode** subcategory.
> 4. Fill out the fields (you may optionally attach a screenshot) and click **Submit**.
>
> Submitting feedback will help Microsoft resolve the issue you encountered.

Failed to locate the package

> Developer Mode package couldn’t be located in Windows Update. Error Code 0x80004005. Learn more.

This error may occur due to a network connectivity problem, Enterprise settings, or the package may be missing.

To fix this issue:

1. Ensure that your computer is connected to the internet.
2. If you're on a domain-joined computer, speak to your network administrator. The Developer Mode package (like all Features on Demand) is blocked by default in WSUS 2.1. In order to unblock the Developer Mode package in the current and previous releases, the following KBs should be allowed in WSUS:
    - 4016509

- 3180030
- 3197985

3. Check for Windows updates in **Settings** → **Updates and Security** → **Windows Updates**.

4. Verify that the Windows Developer Mode package is present in **Settings** → **System** → **Apps & Features** → **Manage optional features** → **Add a feature**. If it's missing, Windows can't find the correct package for your computer.

5. After performing the above steps, *disable* and then *re-enable* Developer Mode to verify the fix.

Failed to install the package

> Developer Mode package failed to install. Error code 0x80004005. Learn more.

This error may occur due to incompatibilities between your build of Windows and the Developer Mode package.

To fix this issue:

1. Check for Windows updates in the **Settings** → **Updates and Security** → **Windows Updates**.
2. Restart your computer to ensure all updates are applied.

Use group policies or registry keys to enable a device

For most developers, you'll want to use the settings app to enable your device for debugging. In certain scenarios (such as automated tests) you can use other ways to enable your Windows desktop device for development.

> **ⓘ Note**
>
> These steps will not enable the SSH server or allow the device to be targeted for remote deployment and debugging.

You can use `gpedit.msc` to set the group policies to enable your device, unless you have *Windows 10 Home* or *Windows 11 Home*. If you do, you'll need to use regedit or PowerShell commands to set the registry keys directly to enable your device.

Use gpedit to enable your device

1. Run `gpedit.msc`.
2. Go to **Local Computer Policy → Computer Configuration → Administrative Templates → Windows Components → App Package Deployment**.
3. Edit the following policies to enable sideloading:

   - Allow all trusted apps to install.

   OR

   Edit the following policies to enable both sideloading and Developer Mode:

   - Allow all trusted apps to install.
   - Allows development of UWP apps and installation from an *Integrated Development Environment (IDE)*.
   - Reboot your machine.

Use regedit to enable your device

1. Run `regedit`.
2. To enable sideloading, set the value of this `DWORD` to `1`:

   `HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\AppModelUnlock\AllowAllTrustedApps`

   OR

   To enable developer mode, set the values of this `DWORD` to `1`:

   `HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\AppModelUnlock\AllowDevelopmentWithoutDevLicense`

Use PowerShell to enable your device

1. Run PowerShell with administrator privileges.
2. To enable sideloading, run this command:

   ```
   PowerShell
   ```

```
PS C:\WINDOWS\system32> reg add
"HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\AppModelU
nlock" /t REG_DWORD /f /v "AllowAllTrustedApps" /d "1"
```

OR

To enable developer mode, run this command:

PowerShell

```
PS C:\WINDOWS\system32> reg add
"HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\AppModelU
nlock" /t REG_DWORD /f /v "AllowDevelopmentWithoutDevLicense" /d "1"
```

Upgrade your device from Windows 8.1 to Windows 10 or 11

When you create or sideload apps on your Windows 8.1 device, you have to install a developer license. If you upgrade your device from Windows 8.1 to Windows 10 or 11, this information remains. Run the following command to remove this information from your upgraded Windows device.

> ⓘ **Note**
>
> This step is not required if you upgrade directly from Windows 8.1 to Windows 10, Version 1511 or later.

To unregister a developer license

1. Run PowerShell with administrator privileges.
2. Run this command:

PowerShell

```
unregister-windowsdeveloperlicense
```

After you unregister your license, you'll need to enable your device for development (as described in this topic) so that you can continue to develop on this device. If you don't,

you may get an error when you debug your app (or if you try to create a package for it). Here's an example of this error:

> Error : DEP0700 : Registration of the app failed.

Install tools for the Windows App SDK

Article • 02/11/2025

Configure your development computer with the tools required to build Windows apps using the Windows App SDK (stable release channel) and WinUI.

Before installing any tools, see System requirements for Windows app development.

> **Important**
>
> This article applies only to the **stable release channel** of the Windows App SDK. For other release channels, see **Install tools for preview and experimental channels of the Windows App SDK**.

Install tools with winget

[Visual Studio 2022 and later] Install the required tools and workloads using the console and one of the following commands. These commands will open Visual Studio Installer with any missing workloads selected, for which you can select **Modify** to install the required workloads.

For C# developers

Visual Studio Community

```
winget install "Visual Studio Community 2022"  --override "--add
Microsoft.VisualStudio.Workload.ManagedDesktop
Microsoft.VisualStudio.ComponentGroup.WindowsAppSDK.Cs" -s msstore
```

For C++ developers

Visual Studio Community

```
winget install "Visual Studio Community 2022"  --override "--add
Microsoft.VisualStudio.Workload.NativeDesktop
Microsoft.VisualStudio.ComponentGroup.WindowsAppSDK.Cpp"  -s msstore
```

Install tools manually

The following sections describe how to install the required tools and workloads manually.

Install Visual Studio

Use the following links to install Visual Studio 2022 (recommended) or Visual Studio 2019. You can choose between the free Visual Studio Community Edition, Visual Studio Professional, or Visual Studio Enterprise. Before installing either, see System requirements for Windows app development.

> **Important**
>
> Visual Studio 2022 is recommended for developing apps using any version of the Windows App SDK (Visual Studio 2019 supports Windows App SDK 1.1 and earlier).

Download Visual Studio 2022

Download Visual Studio 2019

Required workloads and components

During Visual Studio installation, you have the option to install workloads and components (you can also open the Visual Studio Installer and select **Modify** to add workloads and components after installation). We recommend installing the following:

Visual Studio 2022 version 17.1 and later

From within the Visual Studio Installer app:

- On the **Workloads** tab:
  - For C# app development using the Windows App SDK, select **.NET Desktop Development**.
    - Then in the **Installation details** pane of the installation dialog box, select **Windows App SDK C# Templates** (at the bottom of the list).
  - For C++ app development using the Windows App SDK, select **Desktop development with C++**
    - Then in the **Installation details** pane of the installation dialog box, select **Windows App SDK C++ Templates** (at the bottom of the list).

- On the **Individual components** tab, in the **SDKs, libraries, and frameworks** section, make sure **Windows 10 SDK (10.0.19041.0)** is selected.

Visual Studio project and item templates

The Windows App SDK includes Visual Studio project and item templates for creating and developing apps that use the WinUI 3 library to implement the user interface.

Visual Studio 2022 version 17.1 and later

If you followed the instructions in Required workloads and components above, the templates should already be installed.

Select **C#** or **C++** as the language, **Windows** as the platform, and **WinUI** as the Project type to create a new Windows App SDK project.

Optionally, install Template Studio for WinUI (C#) to accelerate the creation of new .NET WinUI apps using a wizard-based UI. Select from a variety of project types and features to generate a project template customized for you.

For more versions of the Windows App SDK, see Downloads for the Windows App SDK.

Hybrid C/C++ runtime library linkage

In releases 1.0.3 and 1.1 Preview 2 and later, the Windows App SDK uses Hybrid C/C++ runtime library linkage (hybrid CRT linkage). This is a CRT linkage technique that simplifies deployment. Whether you're a C++ application developer or a C++ library developer, here are some resources for learning about hybrid CRT linkage:

- Hybrid CRT linkage coding guidelines on GitHub.
- The hybrid CRT linkage segment of the WinUI community call from April 20, 2022.

Next steps

To create your first WinUI 3 app that uses the Windows App SDK, see Create your first WinUI 3 project.

Also see Use the Windows App SDK in an existing project.

Visual Studio project and item templates for Windows apps

Article • 10/24/2022

Visual Studio 2019 (and later) provides many project and item templates that help you build apps for Windows 11 and Windows 10 devices by using C# or C++. This topic describes the templates and helps you choose one for your scenario.

- Project templates include project files, code files, and other assets that are configured to build an app or a component that can be loaded and used by an app.
- Item templates are project files that contain commonly used code and XAML that can be added to a project to reduce development time. For example, you can use an item template to add a new window, page, or control to your app.

For more information about installing and configuring Visual Studio to get access to these templates, see Start developing Windows apps.

WinUI templates

WinUI is the modern native user interface (UI) platform for Windows apps across desktop (.NET and native Win32) and UWP app platforms. WinUI 3 is the latest major version of WinUI, and it transforms WinUI into a full UX framework for desktop Windows apps.

WinUI 3 is available as part of the Windows App SDK. It includes a VSIX package for Visual Studio 2019 (and later) that provides project and item templates that help you get started building apps with a WinUI-based interface.

Template Studio for WinUI (C#) is a Visual Studio 2022 extension that accelerates the creation of new .NET WinUI apps using a wizard-based UI. Select from a variety of project types and features to generate a project template customized for you.

For more information about the available WinUI project and item templates, see WinUI 3 templates in Visual Studio.

UWP templates

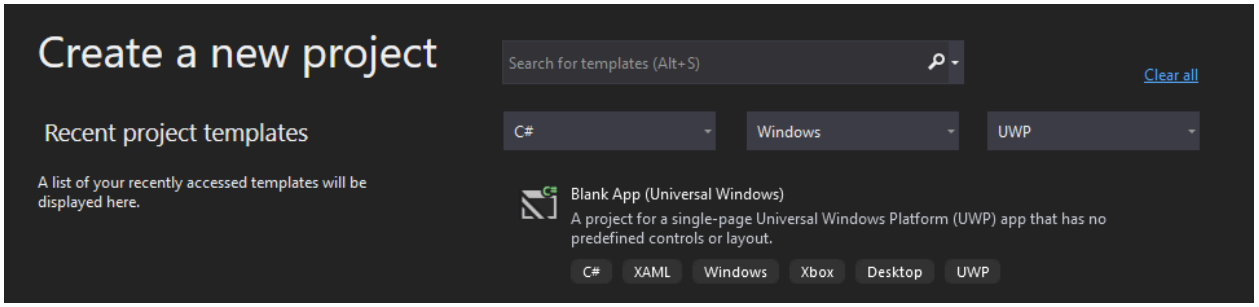
Visual Studio provides a variety of project templates for building UWP apps with C# or C++. To use these project templates, you must include the **Universal Windows Platform**

development workload when you install Visual Studio. For the C++ project templates, you must also include the **C++ (v142) Universal Windows Platforms tools** optional component for the **Universal Windows Platform development** workload.

Template Studio for UWP is a Visual Studio 2022 extension that accelerates the creation of new .NET UWP apps using a wizard-based UI. Select from a variety of project types and features to generate a project template customized for you.

Project templates for C# and UWP

To access the UWP C# project templates when you create a new project in Visual Studio, filter the language to **C#**, the platform to **Windows**, and the project type to **UWP**.



You can use these project templates to create C# UWP apps.

Expand table

Template	Description
Blank App (Universal Windows)	Creates a UWP app. The generated project includes a basic page that derives from the Windows.UI.Xaml.Controls.Page class that you can use to start building your UI.
Unit Test App (Universal Windows)	Creates a unit test project in C# for a UWP app. For more information, see Unit test C# code.

You can use these project templates to build pieces of a C# UWP app.

Expand table

Template	Description
Class Library (Universal Windows)	Creates a managed class library (DLL) in C# that can be used by other UWP apps written in managed code.
Windows Runtime Component (Universal	Creates a Windows Runtime component in C# that can be consumed by any UWP app, regardless of the programming

Template	Description
Windows)	language in which the app is written.
Optional Code Package (Universal Windows)	Creates an optional package with executable C# code that can be loaded by an app. For more information, see Optional packages with executable code.

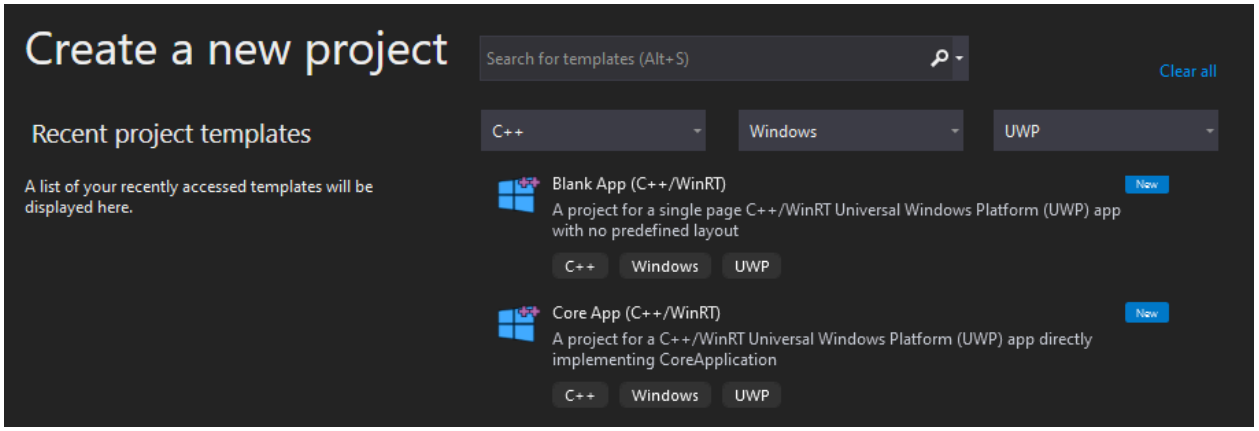
Project templates for C++ and UWP

There are two different technologies you can use to build C++ UWP apps:

- The recommended technology is C++/WinRT. This is a C++ language projection that is implemented entirely in header files, and designed to provide you with first-class access to the modern WinRT API.
- Alternatively, you can use the older C++/CX set of extensions. C++/CX is still supported, but we recommend that you use C++/WinRT instead.

To access the UWP C++ project templates when you create a new project in Visual Studio, filter the language to **C++**, the platform to **Windows**, and the project type to **UWP**.

> **Note**
>
> By default, the **Universal Windows Platform development** workload in Visual Studio only provides access to the C++/CX project templates. To access the C++/WinRT project templates, you must install the C++/WinRT VSIX package.



You can use these project templates to create C++ UWP apps.

Expand table

Template	Description
Blank App (C++/WinRT)	Creates a C++/WinRT UWP app with a XAML user interface. The generated project includes a basic page that derives from the Windows.UI.Xaml.Controls.Page class that you can use to start building your UI.
Core App (C++/WinRT)	Creates a C++/WinRT UWP app that uses CoreApplication to integrate with a variety of UI frameworks instead of a XAML user interface. For a walkthrough that demonstrates how to use this project template to create a simple game that uses DirectX, see Create a simple UWP game with DirectX.
Blank App (Universal Windows - C++/CX)	Creates a C++/WinRT UWP app with a XAML user interface. The generated project includes a basic page that derives from the Windows.UI.Xaml.Controls.Page class in the WinUI library that you can use to start building your UI.
DirectX 11 and XAML App (Universal Windows - C++/CX)	Creates a UWP app that uses DirectX 11 and a **SwapChainPanel** so you can use XAML UI controls. For more information, see DirectX game project templates.
DirectX 11 App (Universal Windows - C++/CX)	Creates a UWP app that uses DirectX 11. For more information, see DirectX game project templates.
DirectX 12 App (Universal Windows - C++/CX)	Creates a UWP app that uses DirectX 12. For more information, see DirectX game project templates.
Unit Test App (Universal Windows - C++/CX)	Creates a unit test project in C++/CX for a UWP app. For more information, see How to test a C++ UWP DLL.

You can use these project templates to build pieces of a C++ UWP app.

Expand table

Template	Description
Windows Runtime Component (C++/WinRT)	Creates a Windows Runtime component in C++/WinRT that can be consumed by any UWP app, regardless of the programming language in which the app is written.
Windows Runtime Component (Universal Windows)	Creates a Windows Runtime component in C++/CX that can be consumed by any UWP app, regardless of the programming language in which the app is written.

Template	Description
DLL (Universal Windows)	A project for creating a dynamic-link library (DLL) in C++/CX that can be used in a UWP app. For more information, see DLLs (C++/CX).
Static Library (Universal Windows)	A project for creating a static library (LIB) in C++/CX that can be used in a UWP app. For more information, see Static libraries (C++/CX).

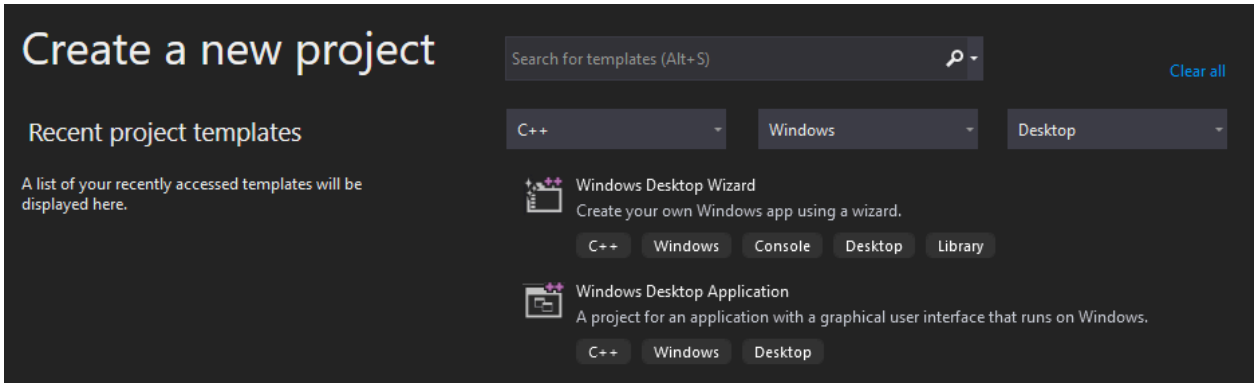
C++ desktop (Win32) templates

Visual Studio provides a variety of project templates for building desktop Windows apps with native C++ and direct access to the Win32 API. To use these project templates, you must include the **Desktop development with C++** workload when you install Visual Studio. This workload includes project templates for building desktop apps, console apps, and libraries.

The recommended technology is C++/WinRT. This is a C++ language projection that is implemented entirely in header files, and designed to provide you with first-class access to the modern WinRT API.

Project templates for C++ desktop apps

To access the C++ project templates for desktop apps when you create a new project in Visual Studio, filter the language to **C++**, the platform to **Windows**, and the project type to **Desktop**.



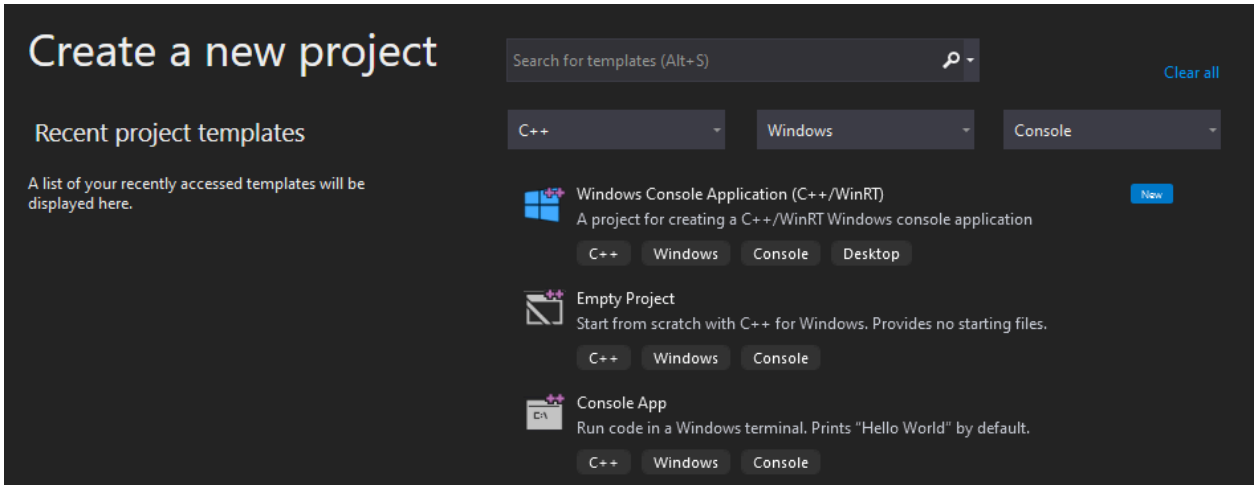
Expand table

Template	Description
Windows Desktop Application	Creates a C++/WinRT client application for Windows desktop. For more information, see Windows Desktop Application (C++/WinRT). This project

Template	Description
(C++/WinRT)	template requires the C++/WinRT VSIX.
Windows Desktop Application	Creates a classic Windows desktop app with C++. For more information, see Walkthrough: Create a traditional Windows Desktop application.
Windows Desktop Wizard	Provides a step-by-step wizard you can use to create one of the following types of projects: a classic Windows desktop app, a console app, a dynamic-link library (DLL), or a static library. For more information, see Windows Desktop Wizard and Walkthrough: Create a traditional Windows Desktop application.
Windows Application Packaging Project	Creates a project that you can use to build a desktop app into an MSIX package. This provides a modern deployment experience, the ability to integrate with Windows features via package extensions, and much more. For more information, see Windows Application Packaging Project.

Project templates for C++ console apps

To access the C++ project templates for console apps, filter the language to **C++**, the platform to **Windows**, and the project type to **Console**.

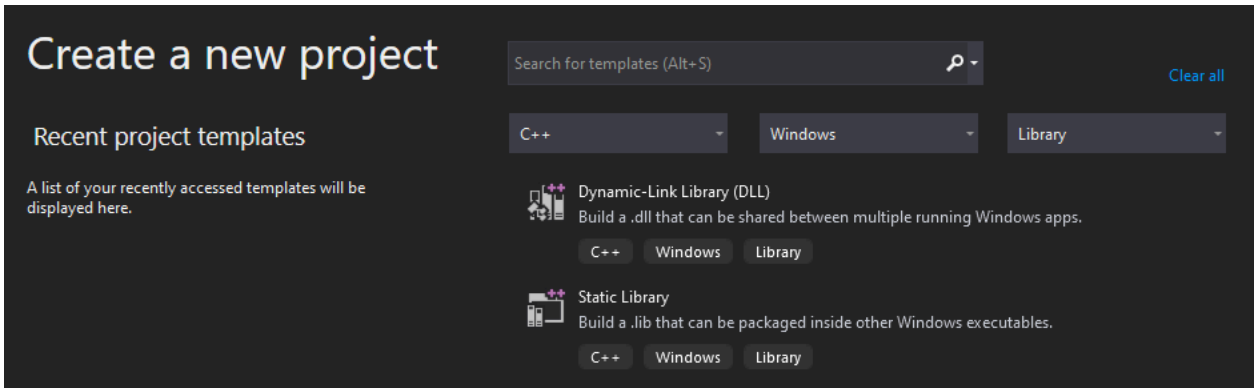


Expand table

Template	Description
Windows Console Application (C++/WinRT)	Creates a C++/WinRT console app without a user interface. For more information, see C++/WinRT quick-start. This project template requires the C++/WinRT VSIX.
Console App	Creates a console app without a user interface. For more information, see Walkthrough: Creating a Standard C++ Program.
Empty Project	An empty project for creating an application, library, or DLL. You must add any code or resources required.

Project templates for C++ libraries

To access the C++ project templates for libraries, filter the language to **C++**, the platform to **Windows**, and the project type to **Library**.



Expand table

Template	Description
Dynamic-Link Library (DLL)	A project for creating a dynamic-link library (DLL). For more information, see Walkthrough: Creating and using a dynamic link library.
Static Library	A project for creating a static library (LIB). For more information, see Walkthrough: Create and use a static library.

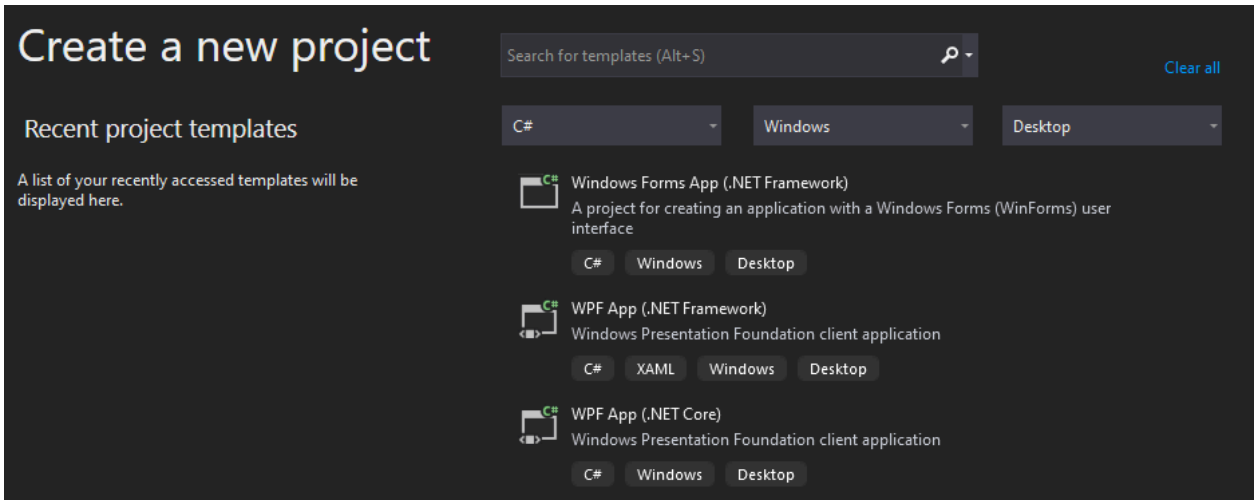
Item templates for C++ desktop apps

The C++ project templates for include many item templates that you can use to perform tasks like adding new files and resources to your project. For a comprehensive list, see Using Visual C++ Add New Item Templates.

.NET templates

Visual Studio provides a variety of project templates for building desktop Windows apps that use .NET and C#. To use these project templates, you must include the **.NET desktop development** workload when you install Visual Studio.

To access the .NET C# project templates when you create a new project in Visual Studio, filter the language to **C#**, the platform to **Windows**, and the project type to **Desktop**.



You can use these project templates to create apps using C# and .NET.

Expand table

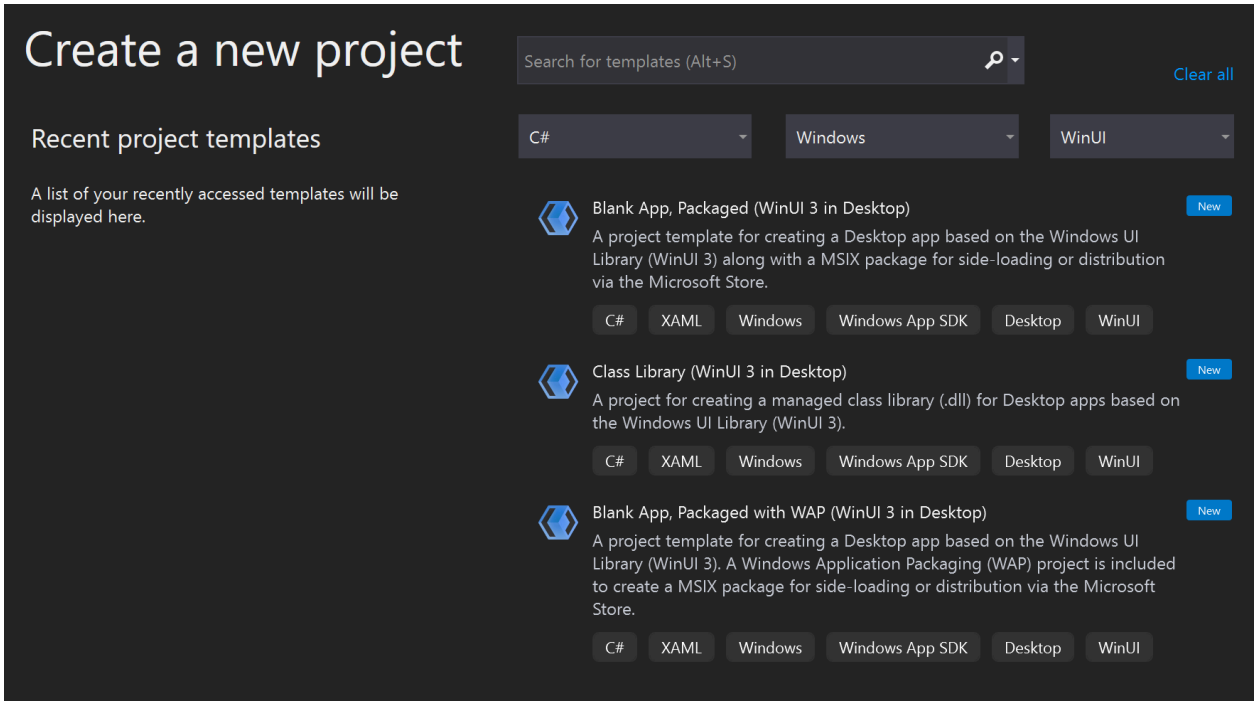
Template	Description
WPF Application	Creates a WPF app that targets .NET 6 (or later). For a walkthrough of this project template, see Create a WPF application.
WPF App (.NET Framework)	Creates a WPF app that targets the .NET Framework. For a walkthrough of this project template, see Tutorial: Create your first WPF application.
Windows Forms App	Creates a Windows Forms app that targets .NET 6 (or later).
Windows Forms App (.NET Framework)	Creates a Windows Forms app that targets the .NET Framework. For a walkthrough of this project template, see Create a Windows Forms app in Visual Studio with C#.
Windows Application Packaging Project	Creates a project that you can use to build a WPF or Windows Forms app into an MSIX package. This provides a modern deployment experience, the ability to integrate with Windows features via package extensions, and much more. For more information, see Windows Application Packaging Project.

WinUI 3 templates in Visual Studio

Article • 07/09/2024

Once you've set up your development computer (see Start developing Windows apps), you're ready to create a WinUI 3 app by starting from one of the WinUI 3 project templates in Visual Studio. This topic describes the available project and item templates.

To access the WinUI 3 project templates, in the **New Project** dialog's drop-down filters, select **C#/C++**, **Windows**, and **WinUI**, respectively. Alternatively, you can search for *WinUI*, and select one of the available C# or C++ templates.



Project templates for WinUI 3

You can use these WinUI 3 project templates to start creating an app.

Blank App, Packaged (WinUI 3 in Desktop)

This project template creates a desktop .NET (C#) or native Win32 (C++) app with a WinUI 3-based user interface. The generated project includes a basic window that derives from the **Microsoft.UI.Xaml.Window** class in the WinUI 3 library that you can use to start building your UI. For more information about using this project template, see Create your first WinUI 3 project.

The features of this project template vary between versions of the Windows App SDK extension.

- **Version 1.0 Preview 2:** Starting with this release, this project template generates an application project with the package manifest and other support needed to build the app into an MSIX package without the use of a separate packaging project. To use this project template, you must also install the single-project MSIX packaging tools extension for Visual Studio.

  > ⓘ **Note**
  >
  > In version 1.0 Preview 2 and later releases, this project template only supports a single executable in the generated MSIX package. If you need to combine multiple executables into a single MSIX package, then you'll need to use the **Blank App, Packaged with Windows Application Packaging Project (WinUI 3 in Desktop)** project template, or add a Windows Application Packaging Project to your solution.

- **Version 1.0 Preview 1 and earlier:** In these releases, this project template generates a solution with a separate Windows Application Packaging Project that is configured to build the app into an MSIX package. You can optionally install the single-project MSIX packaging tools extension for Visual Studio and combine the packaging project settings into your application project so you no longer need to maintain a separate packaging project.

Blank App, Packaged with Windows Application Packaging Project (WinUI 3 in Desktop)

This project template is available in version 1.0 Preview 1 and later releases. It creates a desktop .NET (C#) or native Win32 (C++) app with a WinUI 3-based user interface. The generated project includes a basic window that derives from the **Microsoft.UI.Xaml.Window** class in the WinUI 3 library that you can use to start building your UI. For more info about using this project template, see Create your first WinUI 3 project.

The solution also includes a separate Windows Application Packaging Project that is configured to build the app into an MSIX package. You can optionally install the single-project MSIX packaging tools extension for Visual Studio and combine the packaging project settings into your application project so you no longer need to maintain a separate packaging project.

[Experimental] Blank App (WinUI 3 in UWP)

This project template creates a C# or C++ UWP app that with a WinUI 3-based user interface. The generated project includes a basic page that derives from the **Microsoft.UI.Xaml.Controls.Page** class in the WinUI 3 library, which you can use to start building your UI. For more information about this project template, see Create your first WinUI 3 app.

WinUI project templates for other components

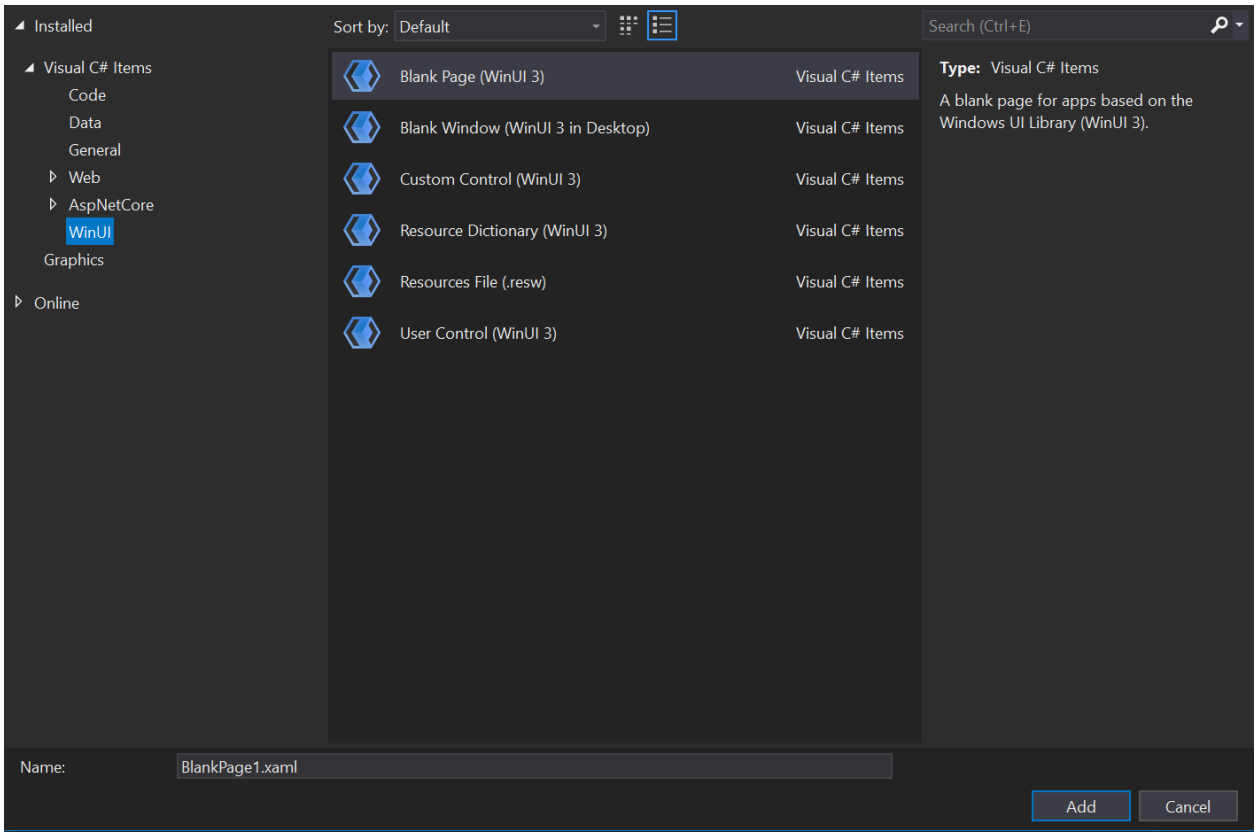
You can use these WinUI 3 project templates to build components that can be loaded and used by a WinUI 3-based app.

Expand table

Template	Language	Description
Class Library (WinUI 3 in Desktop)	C# only	Creates a .NET managed class library (DLL) in C# that can be used by other .NET desktop apps with a WinUI 3-based user interface.
[Experimental] Class Library (WinUI 3 in UWP)	C# only	Creates a managed class library (DLL) in C# that can be used by other UWP apps with a WinUI 3-based user interface.
Windows Runtime Component (WinUI 3)	C++	Creates a Windows Runtime component written in C++/WinRT that can be consumed by any UWP or desktop app with a WinUI 3-based user interface, regardless of the programming language in which the app is written.
[Experimental] Windows Runtime Component (WinUI 3 in UWP)	C#	Creates a Windows Runtime component written in C# that can be consumed by any UWP app with a WinUI 3-based user interface, regardless of the programming language in which the app is written.

Item templates for WinUI 3

The following item templates are available for use in a WinUI 3 project. To access these WinUI 3 item templates, right-click the project node in **Solution Explorer**, select **Add** -> **New item**, and click **WinUI** in the **Add New Item** dialog.



> **Note**
>
> If you have the experimental channel or an older preview release of the Windows App SDK installed, you may see a second set of Item Templates that have the [Experimental] prefix. We recommend that you use those [Experimental] item templates if you're building a non-production/preview app, and use the stable, non-marked item templates if you're building a production desktop app.

Expand table

Template	Language	Description
Blank Page (WinUI 3)	C# and C++	Adds a XAML file and code file that defines a new page derived from the **Microsoft.UI.Xaml.Controls.Page** class in the WinUI 3 library.
Blank Window (WinUI 3 in Desktop)	C# and C++	Adds a XAML file and code file that defines a new window derived from the **Microsoft.UI.Xaml.Window** class in the WinUI 3 library.
Custom Control (WinUI 3)	C# and C++	Adds a code file for creating a templated control with a default style. The templated control is derived from the **Microsoft.UI.Xaml.Controls.Control** class in the WinUI 3 library. For a walkthrough that demonstrates how to use this item template, see Templated XAML controls for UWP and WinUI 3 apps with

Template	Language	Description
		C++/WinRT and Templated XAML controls for UWP and WinUI 3 apps with C#. For more information about templated controls, see Custom XAML Controls.
Resource Dictionary (WinUI 3)	C# and C++	Adds an empty, keyed collection of XAML resources. For more information, see ResourceDictionary and XAML resource references.
Resources File (WinUI 3)	C# and C++	Adds a file for storing string and conditional resources for your app. You can use this item to help localize your app. For more info, see Localize strings in your UI and app package manifest.
User Control (WinUI 3)	C# and C++	Adds a XAML file and code file for creating a user control that derives from the **Microsoft.UI.Xaml.Controls.UserControl** class in the WinUI 3 library. Typically, a user control encapsulates related existing controls and provide its own logic. For more information about user controls, see Custom XAML Controls.

Use the Windows App SDK in an existing project

Article • 01/14/2025

If you have a desktop project in which you want to use the Windows App SDK, then you can install the Windows App SDK NuGet package in your project (the latest version, or any version that you need). Unpackaged apps (that is, apps that don't use MSIX for their deployment technology) *must* follow this procedure if they're to use the Windows App SDK. But packaged apps *can* do it, too.

> **ⓘ Important**
>
> If you're working on a UWP app, then refer to Migrate from UWP to the Windows App SDK.

> **ⓘ Note**
>
> This procedure is supported in C# .NET 6 (and later) projects and C++ desktop projects. Those project types can use NuGet packages from either the stable release channel, the preview release channel, or the experimental release channel.

Prerequisites

- Visual Studio 2019 or later.
- The workloads and components for Windows app development. For more info, see Install tools for the Windows App SDK.

Instructions

1. Open an existing project in Visual Studio.

   > **ⓘ Note**
   >
   > If you have a C# desktop project, then make sure that the **TargetFramework** element in the project file is set to a Windows 10-specific moniker (such as

net6.0-windows10.0.19041.0) so that you can call Windows Runtime APIs. For more info, see Call Windows Runtime APIs in desktop apps.

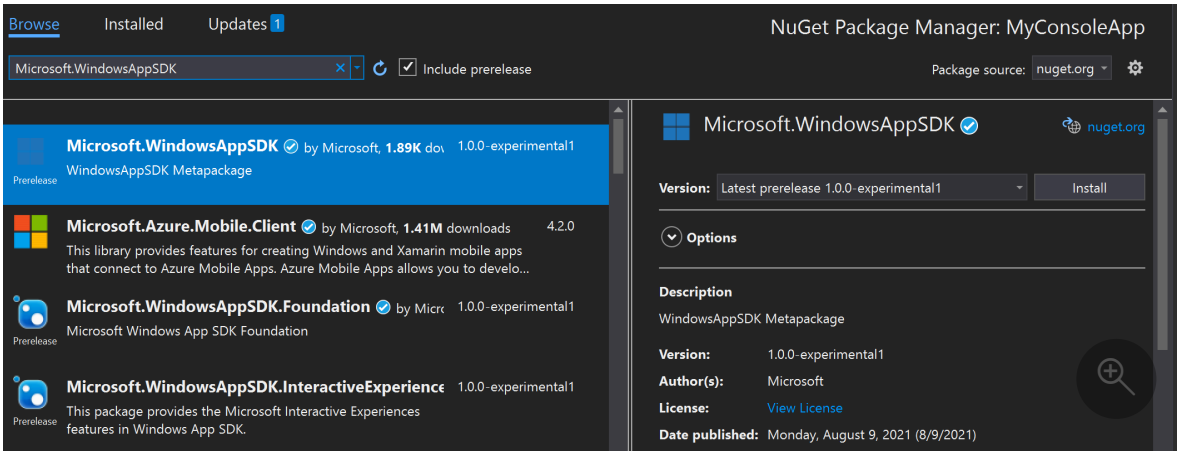
2. Make sure that package references are enabled:
   a. In Visual Studio, click **Tools** > **NuGet Package Manager** > **Package Manager Settings**.
   b. Make sure that **PackageReference** is selected for **Default package management format**.

3. Right-click your project in **Solution Explorer**, and choose **Manage NuGet Packages**.

4. In the **NuGet Package Manager** window, select the **Include prerelease** check box near the top of the window, select the **Browse** tab, and search for one of the following packages:

   - To install one of the 1.0 or later releases, search for the **Microsoft.WindowsAppSDK** package.
   - To install one of the 0.8 releases, search for the **Microsoft.ProjectReunion** package.

5. After you've found the appropriate Windows App SDK NuGet package, select the package, and click **Install** in the right-hand pane of the **NuGet Package Manager** window.



> **Note**
>
> The Windows App SDK NuGet package contains other sub-packages (including **Microsoft.WindowsAppSDK.Foundation**, **Microsoft.WindowsAppSDK.WinUI**, and others) that contain the implementations for specific components in the Windows App SDK. You can't install these sub-packages individually in order to reference only certain

components in your project. You must install the main Windows App SDK NuGet package, which includes all of the components.

6. **For unpackaged apps only**. Before your unpackaged app can use Windows App SDK APIs and components, your app must first load the Windows App SDK runtime to reference the Windows App SDK framework package. For more info, see Use the Windows App SDK runtime for apps packaged with external location or unpackaged and Tutorial: Use the bootstrapper API in an app packaged with external location or unpackaged that uses the Windows App SDK.

7. Your app can now use Windows App SDK APIs and components that are available in the release channel that you installed. For the list of available features, see release channels.

Further info

If your existing project is a C++ project, and you want to call Windows Runtime APIs in the Windows App SDK, then you'll need to add support for C++/WinRT. See Visual Studio support for C++/WinRT, XAML, the VSIX extension, and the NuGet package. Look for info there about the **Microsoft.Windows.CppWinRT NuGet** package. Without that package, your project won't be able to find the namespace header files for Windows Runtime APIs in the Windows App SDK.

If you encounter a *Class not registered* error when you try to use a Windows App SDK component, then you might have to add to your project a dynamic dependency on the Windows App SDK Framework package. For more info, see MSIX framework packages and dynamic dependencies.

Use the Windows App SDK in a WPF app

Article • 08/21/2024

The Windows App SDK is the next evolution in the Windows app development platform. But this topic shows how you can use Windows App SDK APIs (and Windows Runtime APIs) in a Windows Presentation Foundation (WPF) app!

- In many cases, you'll want to recreate your WPF app in the form of a WinUI 3 app. Just one of the advantages of moving to WinUI 3 is to have access to the Fluent Design System (also see Design and code Windows apps). And WinUI 3 is part of the Windows App SDK—so, naturally, a WinUI 3 app can use the other Windows App SDK features and APIs, as well. This topic doesn't cover the process of migrating your WPF app to WinUI 3.
- But if you find that you're using features of WPF that aren't yet available in WinUI 3, then you can still use Windows App SDK features (such as App Lifecycle, MRT Core, DWriteCore, and others) in your WPF app. This topic shows you how.

And in case you don't already have an existing WPF project—or you want to practice the process—this topic includes steps to create a WPF project so that you can follow along and configure it to call Windows App SDK APIs.

Prerequisites

1. Install tools for the Windows App SDK.
2. This topic covers both unpackaged and packaged WPF apps. If your WPF app is unpackaged (which WPF apps are by default), then ensure that all dependencies for unpackaged apps are installed (see Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged). A quick way to do that is to visit Latest downloads for the Windows App SDK, then download and unzip and run one of the stable release **Runtime downloads**.

> **Important**
>
> The version of the **Runtime** that you install needs to match the version of the **Microsoft.WindowsAppSDK** NuGet package that you'll install in a later step.

For more info about the terms *unpackaged* and *packaged*, see Advantages and disadvantages of packaging your app.

Create a WPF project if you don't already have one

If you already have a WPF project, then you can move on to the next section.

1. In Visual Studio, create a new C# **WPF Application** project (which is a .NET project). Be careful that you choose the project template with the exact name **WPF Application**, and not the **WPF App (.NET Framework)** one.
2. Give the project a name, and accept any default options.

You now have a project that builds an unpackaged WPF app.

Configure your WPF project for Windows App SDK support

First we'll edit the project file.

1. In **Solution Explorer**, right-click your project, and choose **Edit Project File**.

2. This step enables you to call Windows Runtime (WinRT) APIs (including Windows App SDK APIs). Inside the **PropertyGroup** element is the **TargetFramework** element, which is set to a value such as *net6.0*. Append to that target framework value a moniker (specifically, a Target Framework Moniker). For example, use the following if your app targets Windows 10, version 2004:

   ```
   XML

   <TargetFramework>net8.0-windows10.0.19041.0</TargetFramework>
   ```

3. Also inside the **PropertyGroup** element, add a RuntimeIdentifiers element, as shown below. If you're targeting .NET 8 or later, then use the value `win-x86;win-x64;win-arm64` instead.

   ```
   XML

   <RuntimeIdentifiers>win-x86;win-x64;win-arm64</RuntimeIdentifiers>
   ```

4. By default, a WPF app is unpackaged (meaning that it isn't installed by using MSIX). An unpackaged app must initialize the Windows App SDK runtime before using any other feature of the Windows App SDK. You can do that automatically when your app starts via *auto-initialization*. You just set (also inside the

PropertyGroup element) the `WindowsPackageType` project property appropriately, like this:

```
XML
```

```xml
<WindowsPackageType>None</WindowsPackageType>
```

If you have advanced needs (such as custom error handling, or to load a specific version of the Windows App SDK), then instead of *auto-initialization* you can call the bootstrapper API explicitly—for more info, see Use the Windows App SDK runtime for apps packaged with external location or unpackaged.

5. Save and close the project file.

Next, we'll install the Windows App SDK NuGet package in the project.

6. In **Solution Explorer**, right-click the **Dependencies** node of your project, and choose **Manage Nuget Packages...**.
7. In the **NuGet Package Manager** window, select the **Browse** tab, and install the *Latest stable* **Microsoft.WindowsAppSDK** package.

Use some Windows App SDK features in your WPF app

This section offers a very simple example of calling Windows App SDK APIs from a WPF app. It uses the MRT Core feature (see Manage resources with MRT Core). If this example works for your WPF project (and if you created a new one for this walkthrough, then it will), then you can follow these steps.

1. Add the following markup to `MainWindow.xaml` (you could paste it inside the root **Grid**):

```
XAML
```

```xaml
<StackPanel>
    <Button HorizontalAlignment="Center" Click="Button_Click">Click me!
</Button>
    <TextBlock HorizontalAlignment="Center" x:Name="myTextBlock">Hello,
World!</TextBlock>
</StackPanel>
```

2. Now we'll add some code that uses the ResourceManager class in the Windows App SDK to load a string resource.

a. Add a new **Resources File (.resw)** item to your project (leave it with the default name of *Resources.resw*).

b. With the resources file open in the editor, create a new string resource with the following properties.

- Name: **Message**
- Value: **Hello, resources!**

c. Save and close the resources file.

d. In `MainWindow.xaml.cs`, add the following event handler:

```
C#

private void Button_Click(object sender, RoutedEventArgs e)
{
    // Construct a resource manager using the resource index generated
during build.
    var manager =
      new
Microsoft.Windows.ApplicationModel.Resources.ResourceManager();

    // Look up a string in the resources file using the string's name.
    myTextBlock.Text =
manager.MainResourceMap.GetValue("Resources/Message").ValueAsString;
}
```

3. Build the project, and run the app. Click the button to see the string `Hello, resources!` displayed.

> **Tip**
>
> If at runtime you see a message box indicating that the application needs a particular version of the Windows App Runtime, and asks whether you want to install it now, then click **Yes**. That will take you to **Latest downloads for the Windows App SDK**. For more info, see the **Prerequisites** section above.

Also see Runtime architecture to learn more about the *Framework* package dependency that your app takes when it uses the Windows App SDK, and the additional components required to work in an unpackaged app.

Package and deploy your WPF app with MSIX

Some Windows features and APIs (including the Windows App SDK notifications APIs) require your app to have *package identity* at runtime (in other words, your app needs to be *packaged*). For more info, see Features that require package identity.

1. In **Solution Explorer** in Visual Studio, right-click the solution, and choose **Add** > **New Project...**.
2. In the **Add a new project** dialog box, search for *packaging*, choose the *C#* **Windows Application Packaging Project** project template, and click **Next**.
3. Name the project, and click **Create**.
4. We want to specify which applications in the solution are to be included in the package. So in the packaging project (*not* the WPF project), right-click the **Dependencies** node, and choose **Add Project Reference...**.
5. In the list of projects in the solution, choose your WPF project, and click **OK**.
6. Expand the packaging project's **Dependencies** > **Applications** node, and confirm that your WPF project is referenced and highlighted in bold. This means that it will be used as a starting point for the package.
7. Right-click the packaging project, and choose **Set As Startup Project**.
8. Right-click the WPF project, and choose **Edit Project File**.
9. Delete `<WindowsPackageType>None</WindowsPackageType>`, save, and close.
10. In the **Solution Platforms** drop-down, pick *x64* (instead of *Any Cpu*).
11. Confirm that you can build and run.

Now that you've packaged your WPF app, you can call APIs that require package identity. So in `MainWindow.xaml.cs`, edit your event handler to look like this:

C#

```
private void Button_Click(object sender, RoutedEventArgs e)
{
    var notification = new AppNotificationBuilder()
        .AddArgument("action", "viewConversation")
        .AddArgument("conversationId", "9813")
        .AddText("Andrew sent you a picture")
        .AddText("Check this out, The Enchantments in Washington!")
        .BuildNotification();

    AppNotificationManager.Default.Show(notification);
}
```

Build and run again. Click the button, and confirm that a toast notification is displayed. When called from a process that lacks package identity at runtime, the notifications APIs throw an exception.

> ⓘ **Note**

The steps in this section showed you how to create a *packaged app*. An alternative is to create a *packaged app with external location*. For a reminder of all these terms, see **Advantages and disadvantages of packaging your app**.

Use the Windows App SDK in a Windows Forms (WinForms) app

Article • 08/21/2024

The Windows App SDK is the next evolution in the Windows app development platform. But this topic shows how you can use Windows App SDK APIs (and Windows Runtime APIs) in a Windows Forms (WinForms) app!

- In many cases, you'll want to recreate your WinForms app in the form of a WinUI 3 app. Just one of the advantages of moving to WinUI 3 is to have access to the Fluent Design System (also see Design and code Windows apps). And WinUI 3 is part of the Windows App SDK—so, naturally, a WinUI 3 app can use the other Windows App SDK features and APIs, as well. This topic doesn't cover the process of migrating your WinForms app to WinUI 3.
- But if you find that you're using features of WinForms that aren't yet available in WinUI 3, then you can still use Windows App SDK features (such as App Lifecycle, MRT Core, DWriteCore, and others) in your WinForms app. This topic shows you how.

And in case you don't already have an existing WinForms project—or you want to practice the process—this topic includes steps to create a WinForms project so that you can follow along and configure it to call Windows App SDK APIs.

Prerequisites

1. Install tools for the Windows App SDK.
2. This topic covers both unpackaged and packaged WinForms apps. If your WinForms app is unpackaged (which WinForms apps are by default), then ensure that all dependencies for unpackaged apps are installed (see Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged). A quick way to do that is to visit Latest downloads for the Windows App SDK, then download and unzip and run one of the stable release **Runtime downloads**.

> **ⓘ Important**
>
> The version of the **Runtime** that you install needs to match the version of the **Microsoft.WindowsAppSDK** NuGet package that you'll install in a later step.

For more info about the terms *unpackaged* and *packaged*, see Advantages and disadvantages of packaging your app.

Create a WinForms project if you don't already have one

If you already have a WinForms project, then you can move on to the next section.

1. In Visual Studio, create a new C# **Windows Forms App** project (which is a .NET project). Be careful that you choose the project template with the exact name **Windows Forms App**, and not the **Windows Forms App (.NET Framework)** one.
2. Give the project a name, and accept any default options.

You now have a project that builds an unpackaged WinForms app.

Configure your WinForms project for Windows App SDK support

First we'll edit the project file.

1. In **Solution Explorer**, right-click your project, and choose **Edit Project File**.

2. This step enables you to call Windows Runtime (WinRT) APIs (including Windows App SDK APIs). Inside the **PropertyGroup** element is the **TargetFramework** element, which is set to a value such as *net6.0*. Append to that target framework value a moniker (specifically, a Target Framework Moniker). For example, use the following if your app targets Windows 10, version 2004:

   ```
   XML

   <TargetFramework>net8.0-windows10.0.19041.0</TargetFramework>
   ```

3. Also inside the **PropertyGroup** element, add a RuntimeIdentifiers element, like this:

   ```
   XML

   <RuntimeIdentifiers>win-x86;win-x64;win-arm64</RuntimeIdentifiers>
   ```

4. By default, a WinForms app is unpackaged (meaning that it isn't installed by using MSIX). An unpackaged app must initialize the Windows App SDK runtime before using any other feature of the Windows App SDK. You can do that automatically

when your app starts via *auto-initialization*. You just set (also inside the **PropertyGroup** element) the `WindowsPackageType` project property appropriately, like this:

```
XML

<WindowsPackageType>None</WindowsPackageType>
```

If you have advanced needs (such as custom error handling, or to load a specific version of the Windows App SDK), then instead of *auto-initialization* you can call the bootstrapper API explicitly—for more info, see Use the Windows App SDK runtime for apps packaged with external location or unpackaged.

5. Save and close the project file.

Next, we'll install the Windows App SDK NuGet package in the project.

6. In **Solution Explorer**, right-click the **Dependencies** node of your project, and choose **Manage Nuget Packages...**.
7. In the **NuGet Package Manager** window, select the **Browse** tab, and install the *Latest stable* **Microsoft.WindowsAppSDK** package.

Use some Windows App SDK features in your WinForms app

This section offers a very simple example of calling Windows App SDK APIs from a WinForms app. It uses the MRT Core feature (see Manage resources with MRT Core). If this example works for your WinForms project (and if you created a new one for this walkthrough, then it will), then you can follow these steps.

1. Open `Form1.cs` (using the **View Designer** command), and drag a **Button** and a **Label** out of the **Toolbox** and onto the designer.

2. Double-click *button1* to generate an event handler.

3. Now we'll add some code that uses the ResourceManager class in the Windows App SDK to load a string resource.

   a. Add a new **Resources File (.resw)** item to your project (leave it with the default name of *Resources.resw*).

   b. With the resources file open in the editor, create a new string resource with the following properties.

- Name: **Message**
- Value: **Hello, resources!**

c. Save and close the resources file.

d. Open `Form1.cs` (using the **View Code** command), and edit the event handler to look like this:

```
C#

private void button1_Click(object sender, EventArgs e)
{
    // Construct a resource manager using the resource index generated
during build.
    var manager =
        new
Microsoft.Windows.ApplicationModel.Resources.ResourceManager();

    // Look up a string in the resources file using the string's name.
    label1.Text =
manager.MainResourceMap.GetValue("Resources/Message").ValueAsString;
}
```

4. Build the project, and run the app. Click the button to see the string `Hello, resources!` displayed.

> **Tip**
>
> If at runtime you see a message box indicating that the application needs a particular version of the Windows App Runtime, and asks whether you want to install it now, then click **Yes**. That will take you to **Latest downloads for the Windows App SDK**. For more info, see the **Prerequisites** section above.

Also see Runtime architecture to learn more about the *Framework* package dependency that your app takes when it uses the Windows App SDK, and the additional components required to work in an unpackaged app.

Package and deploy your WinForms app with MSIX

Some Windows features and APIs (including the Windows App SDK notifications APIs) require your app to have *package identity* at runtime (in other words, your app needs to be *packaged*). For more info, see Features that require package identity.

1. In **Solution Explorer** in Visual Studio, right-click the solution, and choose **Add** > **New Project...**.
2. In the **Add a new project** dialog box, search for *packaging*, choose the C# **Windows Application Packaging Project** project template, and click **Next**.
3. Name the project, and click **Create**.
4. We want to specify which applications in the solution are to be included in the package. So in the packaging project (*not* the WinForms project), right-click the **Dependencies** node, and choose **Add Project Reference...**.
5. In the list of projects in the solution, choose your WinForms project, and click **OK**.
6. Expand the packaging project's **Dependencies** > **Applications** node, and confirm that your WinForms project is referenced and highlighted in bold. This means that it will be used as a starting point for the package.
7. Right-click the packaging project, and choose **Set As Startup Project**.
8. Right-click the WinForms project, and choose **Edit Project File**.
9. Delete `<WindowsPackageType>None</WindowsPackageType>`, save, and close.
10. In the **Solution Platforms** drop-down, pick *x64* (instead of *Any Cpu*).
11. Confirm that you can build and run.

Now that you've packaged your WinForms app, you can call APIs that require package identity. So open `Form1.cs` (using the **View Code** command), and edit the event handler to look like this:

C#

```
private void button1_Click(object sender, EventArgs e)
{
    var notification = new AppNotificationBuilder()
        .AddArgument("action", "viewConversation")
        .AddArgument("conversationId", "9813")
        .AddText("Andrew sent you a picture")
        .AddText("Check this out, The Enchantments in Washington!")
        .BuildNotification();

    AppNotificationManager.Default.Show(notification);
}
```

Build and run again. Click the button, and confirm that a toast notification is displayed. When called from a process that lacks package identity at runtime, the notifications APIs throw an exception.

> **Note**
>
> The steps in this section showed you how to create a *packaged app*. An alternative is to create a *packaged app with external location*. For a reminder of all these terms,

see Advantages and disadvantages of packaging your app.

Update existing projects to a different release of the Windows App SDK

Article • 04/19/2023

If you created a project with an earlier version of the Windows App SDK (previously called Project Reunion) or WinUI 3, then you can update the project to use a more recent release. To learn more about what's currently available in each release channel, see Windows App SDK release channels.

> **Note**
>
> These instructions might have issues due to the uniqueness of each app's individual scenario. Please carefully follow them, and if you find an issue then please file a bug against the microsoft-ui-xaml GitHub repo.

Update between versions released after 1.0

If your project isn't referencing the version of the Windows App SDK NuGet package that you need, then you can use the **NuGet Package Manager** in Visual Studio to update your project's NuGet package references. For example, if you create a new project by using a stable release of the Windows App SDK VSIX, then your project will reference a stable release of the Windows App SDK. But you can easily reconfigure that project to reference, say, an experimental release of the Windows App SDK. Or reconfigure it to reference the latest stable release.

For steps, see the instructions in Use the Windows App SDK in an existing project.

Update from 0.8 to 1.0

If you created a project using version 0.8 (for example, version 0.8.4), then you can follow these instructions to update your project to the 1.0 release.

Prerequisite: Download and install the latest release of the Windows App SDK. For more information, see Install tools for the Windows App SDK.

Instructions

1. In the `.wapproj` file, if your **TargetPlatformMinVersion** is older than `10.0.17763.0`, then change it to `10.0.17763.0`.

2. In Visual Studio, go to **Tools** > **Nuget Package Manager** > **Package Manager Console**. This process consists of uninstalling existing Project Reunion package references from `.csproj`/`.vcxproj` and `.wapproj` files, and then installing the `WindowsAppSDK` package references to those files.

3. Enter the following commands to uninstall existing `ProjectReunion` packages from your `.csproj`/`.vcxproj`

```
Console

uninstall-package Microsoft.ProjectReunion -ProjectName {yourProject}
uninstall-package Microsoft.ProjectReunion.Foundation -ProjectName
{yourProject}
uninstall-package Microsoft.ProjectReunion.WinUI -ProjectName
{yourProject}
```

4. Then, run the following to uninstall existing `ProjectReunion` packages from your `.wapproj`:

```
Console

uninstall-package Microsoft.ProjectReunion
uninstall-package Microsoft.ProjectReunion.WinUI
```

5. Now run the commands to install the stable `WindowsAppSDK` package.

6. To add the `WindowsAppSDK` package reference to your `.csproj`/`.vcxproj`:

```
Console

install-package Microsoft.WindowsAppSDK -ProjectName {yourProject} -
Version 1.0.0
```

7. To add the `WindowsAppSDK` package reference to your `.wapproj`:

```
Console

install-package Microsoft.WindowsAppSDK -Version 1.0.0
```

Update from 0.8 or 0.8 Preview to 1.0 Experimental or Preview 3

> **ⓘ Important**
>
> Version 1.0 Preview 1 and Preview 2 contain a critical bug. If you've already installed one of these previews, see Important issue impacting 1.0 Preview 1 and Preview 2. We recommend using version Version 1.0 Preview 3 (1.0.0-preview3) instead.

If you created a project using version 0.8 Preview or any version of 0.8 (for example, version 0.8.1), you can follow these instructions to update your project to the 1.0 Preview 3 or Experimental release.

Before starting, make sure you have all the Windows App SDK prerequisites installed, including the latest VSIX and NuGet package. For more details, see Install tools for the Windows App SDK.

First, do the following:

- In the .wapproj file, if your **TargetPlatformMinVersion** is older than 10.0.17763.0, change it to 10.0.17763.0.

Next, make these changes to your project:

1. In Visual Studio, go to **Tools** > **Nuget Package Manager** > **Package Manager Console**.
2. Enter the following commands for 1.0 Preview 3:

   Console

   ```
   uninstall-package Microsoft.ProjectReunion -ProjectName {yourProject}
   uninstall-package Microsoft.ProjectReunion.Foundation -ProjectName
   {yourProject}
   uninstall-package Microsoft.ProjectReunion.WinUI -ProjectName
   {yourProject}
   install-package Microsoft.WindowsAppSDK -Version 1.0.0-preview3 -
   ProjectName {yourProjectName}
   ```

   Or the following commands for 1.0 Experimental:

   Console

   ```
   uninstall-package Microsoft.ProjectReunion -ProjectName {yourProject}
   uninstall-package Microsoft.ProjectReunion.Foundation -ProjectName
   ```

```
{yourProject}
uninstall-package Microsoft.ProjectReunion.WinUI -ProjectName
{yourProject}
install-package Microsoft.WindowsAppSDK -Version 1.0.0-experimental1 -
ProjectName {yourProjectName}
```

3. Make the following changes in your Application (package).wapproj:

   a. Remove this item group (if you're updating from a different version than 0.8.0, you will see that corresponding version number referenced in this item group):

   XML

   ```
   <ItemGroup>
       <PackageReference Include="Microsoft.ProjectReunion" Version="
   [0.8.0]">
       <IncludeAssets>build</IncludeAssets>
       </PackageReference>
       <PackageReference Include="Microsoft.ProjectReunion.WinUI"
   Version="[0.8.0]">
       <IncludeAssets>build</IncludeAssets>
       </PackageReference>
   </ItemGroup>
   ```

   b. Add this item group to replace it with 1.0 Preview 3:

   XML

   ```
   <ItemGroup>
       <PackageReference Include="Microsoft.WindowsAppSDK" Version="
   [1.0.0-preview3]">
       <IncludeAssets>build</IncludeAssets>
       </PackageReference>
   </ItemGroup>
   ```

   Or this item group to replace it with 1.0 Experimental:

   XML

   ```
   <ItemGroup>
       <PackageReference Include="Microsoft.WindowsAppSDK" Version="
   [1.0.0-experimental1]">
       <IncludeAssets>build</IncludeAssets>
       </PackageReference>
       <PackageReference Include="Microsoft.WindowsAppSDK.WinUI"
   Version="[1.0.0-experimental1]">
       <IncludeAssets>build</IncludeAssets>
       </PackageReference>
   </ItemGroup>
   ```

4. Make the following changes to your project (.csproj or .vcproj) file:

    a. Remove this item group (if you're updating from a different version than 0.8.0, you will see that corresponding version number referenced in this item group):

    ```
    XML
    ```

    ```xml
    <ItemGroup>
        <PackageReference Include="Microsoft.ProjectReunion"
    Version="0.8.0" />
        <PackageReference Include="Microsoft.ProjectReunion.Foundation"
    Version="0.8.0" />
        <PackageReference Include="Microsoft.ProjectReunion.WinUI"
    Version="0.8.0" />
        <Manifest Include="$(ApplicationManifest)" />
    </ItemGroup>
    ```

    b. Add this item group to replace it with 1.0 Preview 3:

    ```
    XML
    ```

    ```xml
    <ItemGroup>
        <PackageReference Include="Microsoft.WindowsAppSDK"
    Version="1.0.0-preview3" />
        <Manifest Include="$(ApplicationManifest)" />
    </ItemGroup>
    ```

    Or this item group to replace it with 1.0 Experimental:

    ```
    XML
    ```

    ```xml
    <ItemGroup>
        <PackageReference Include="Microsoft.WindowsAppSDK"
    Version="1.0.0-experimental1" />
        <PackageReference Include="Microsoft.WindowsAppSDK.Foundation"
    Version="1.0.0-experimental1" />
        <PackageReference Include="Microsoft.WindowsAppSDK.WinUI"
    Version="1.0.0-experimental1" />
        <Manifest Include="$(ApplicationManifest)" />
    </ItemGroup>
    ```

5. If your solution fails to build, clean the build output, restart Visual Studio, and try re-running the app.

Update from 0.8 Preview to 0.8 or between stable 0.8 versions

If you created a project using version 0.8 Preview, you can follow these instructions to update your project to a stable version of 0.8. These instructions also apply if you've created a project with an older stable version of 0.8 (for example, 0.8.0) and want to update your project to a newer stable version (for example, 0.8.2).

> **Note**
>
> You may be able to automatically update your project through the Visual Studio Extension Manager, without going through the manual steps below. In Visual Studio 2019, click on **Extensions** > **Manage Extensions** and select **Updates** from the left menu bar. Select "Project Reunion" from the list and click **Update**.

Before starting, make sure you have all the Windows App SDK prerequisites installed, including the latest VSIX and NuGet package. For more details, see Install tools for the Windows App SDK.

First, do the following:

- In the .wapproj file, if your **TargetPlatformMinVersion** is older than 10.0.17763.0, change it to 10.0.17763.0.

Next, make these changes to your project:

1. In Visual Studio, go to **Tools** > **Nuget Package Manager** > **Package Manager Console**.
2. Enter the following commands:

   Console

   ```
   uninstall-package Microsoft.ProjectReunion -ProjectName {yourProject}
   uninstall-package Microsoft.ProjectReunion.Foundation -ProjectName
   {yourProject}
   uninstall-package Microsoft.ProjectReunion.WinUI -ProjectName
   {yourProject}
   install-package Microsoft.ProjectReunion -Version 0.8.2 -ProjectName
   {yourProjectName}
   ```

3. Make the following changes in your Application (package).wapproj:

   a. Remove this item group (if you're updating from a different version than 0.8 Preview, you will see that corresponding version number referenced in this item group):

      XML

```
<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.8.0-preview]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="[0.8.0-preview]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

b. Add this item group to replace it:

XML

```
<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.8.2]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="[0.8.2]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

4. Make the following changes to your project (.csproj or .vcproj) file:
   a. Remove this item group (if you're updating from a different version than 0.8 Preview, you will see that corresponding version number referenced in this item group):

XML

```
<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion"
Version="0.8.0-preview" />
    <PackageReference Include="Microsoft.ProjectReunion.Foundation"
Version="0.8.0-preview" />
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="0.8.0-preview" />
    <Manifest Include="$(ApplicationManifest)" />
</ItemGroup>
```

   b. Add this item group to replace it:

XML

```
<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion"
```

```
Version="0.8.2" />
    <PackageReference Include="Microsoft.ProjectReunion.Foundation"
Version="0.8.2" />
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="0.8.2" />
    <Manifest Include="$(ApplicationManifest)" />
</ItemGroup>
```

5. If your solution fails to build, clean the build output, restart Visual Studio, and try re-running the app.

Update from 0.5 to 0.8

If you created a project using version 0.5 stable, you can follow these instructions to update your project to version 0.8 stable.

> **Note**
>
> You may be able to automatically update your project through the Visual Studio Extension Manager, without going through the manual steps below. In Visual Studio 2019, click on **Extensions** > **Manage Extensions** and select **Updates** from the left menu bar. Select "Project Reunion" from the list and click **Update**.

Before starting, make sure you have all the Windows App SDK prerequisites installed, including the latest VSIX and NuGet package. For more details, see Install tools for the Windows App SDK.

First, do the following:

- In the .wapproj file, if your **TargetPlatformMinVersion** is older than 10.0.17763.0, change it to 10.0.17763.0.

Next, make these changes to your project:

1. In Visual Studio, go to **Tools** > **Nuget Package Manager** > **Package Manager Console**.

2. Enter the following commands:

```
Console

uninstall-package Microsoft.ProjectReunion -ProjectName {yourProject}
uninstall-package Microsoft.ProjectReunion.Foundation -ProjectName
{yourProject}
uninstall-package Microsoft.ProjectReunion.WinUI -ProjectName
```

```
{yourProject}
install-package Microsoft.ProjectReunion -Version 0.8.0 -ProjectName
{yourProjectName}
```

3. Add the following line to your project (.csproj or .vcproj) file, inside the first `<PropertyGroup>`:

```XML
<UseWinUI>true</UseWinUI>
```

4. Make the following changes in your Application (package).wapproj:

   a. Add this section:

```XML
<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.8.0]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="[0.8.0]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

   b. Locate the following line:

```XML
<AssetTargetFallback>net5.0-
windows$(TargetPlatformVersion);$(AssetTargetFallback)
</AssetTargetFallback>
```

   Move this line and place it on a new line directly beneath the `<TargetPlatformVersion>` tag.

   c. Remove this item group (if you're updating from an earlier version than 0.5.7, you will see an earlier version number referenced in this item group):

```XML
<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.5.7]">
```

```
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="[0.5.7]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

5. If your solution fails to build, clean the build output, restart Visual Studio, and try re-running the app.

Update from 0.5 Preview to 0.8 Preview

If you created a project using version 0.5 preview, you can follow these instructions to update your project to use version 0.8 preview.

> **Note**
>
> You may be able to automatically update your project through the Visual Studio Extension Manager, without going through the manual steps below. In Visual Studio 2019, click on **Extensions** > **Manage Extensions** and select **Updates** from the left menu bar. Select "Project Reunion" from the list and click **Update**.

Before starting, make sure you have all the Windows App SDK prerequisites installed, including the latest VSIX and NuGet package. For more details, see Install tools for the Windows App SDK.

First, do the following:

- In the .wapproj file, if your **TargetPlatformMinVersion** is older than 10.0.17763.0, change it to 10.0.17763.0.
- The default project templates for both C++ and C# apps included the following lines. The `Application.Suspending` event is no longer called for desktop apps, so be sure to remove these lines (and any other uses of this event) if they are still present in your code:

  C#

  ```
  this.Suspending += OnSuspending;
  ```

  C++

```
Suspending({ this, &App::OnSuspending });
```

Next, make these changes to your project:

1. In Visual Studio, go to **Tools** > **Nuget Package Manager** > **Package Manager Console**.

2. Enter the following commands:

```
Console

uninstall-package Microsoft.ProjectReunion -ProjectName {yourProject}
uninstall-package Microsoft.ProjectReunion.Foundation -ProjectName
{yourProject}
uninstall-package Microsoft.ProjectReunion.WinUI -ProjectName
{yourProject}
install-package Microsoft.ProjectReunion -Version 0.8.0-preview -
ProjectName {yourProjectName}
```

3. Make the following changes in your Application (package).wapproj:

   a. Add this section:

```
XML

<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.8.0-preview]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="[0.8.0-preview]">
    <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

   b. Add the following line to a new line directly beneath the `<TargetPlatformVersion>` tag.

```
XML

<AssetTargetFallback>net5.0-
windows$(TargetPlatformVersion);$(AssetTargetFallback)
</AssetTargetFallback>
```

   c. Remove this line:

```
XML

<AppxTargetsLocation
Condition="'$(AppxTargetsLocation)'==''">$(MSBuildThisFileDirectory)
build\</AppxTargetsLocation>
```

And these lines:

```
XML

<Import Project="$(Microsoft_ProjectReunion_AppXReference_props)" />
<Import Project="$(Microsoft_WinUI_AppX_targets)" />
```

And this item group:

```
XML

<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.5.0]" GeneratePathProperty="true">
      <ExcludeAssets>all</ExcludeAssets>
    </PackageReference>
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="[0.5.0]" GeneratePathProperty="true">
      <ExcludeAssets>all</ExcludeAssets>
    </PackageReference>
</ItemGroup>
```

4. Make the following changes to your project (.csproj or .vcproj) file:

   a. Remove this item group:

```
XML

<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion"
Version="0.5.0-prerelease" />
    <PackageReference Include="Microsoft.ProjectReunion.Foundation"
Version="0.5.0-prerelease" />
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="0.5.0-prerelease" />
    <Manifest Include="$(ApplicationManifest)" />
</ItemGroup>
```

   b. Add this item group:

```
XML
```

```
<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion"
Version="0.8.0-preview" />
    <PackageReference Include="Microsoft.ProjectReunion.Foundation"
Version="0.8.0-preview" />
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="0.8.0-preview" />
    <Manifest Include="$(ApplicationManifest)" />
</ItemGroup>
```

5. If your solution fails to build, clean the build output, restart Visual Studio, and try re-running the app.

Update from 0.5 Preview to 0.5

If you created a project using version 0.5 preview, you can follow these instructions to update your project to stable version 0.5.7.

Before starting, make sure you have all the Windows App SDK prerequisites installed, including the latest VSIX and NuGet package. For more details, see Install tools for the Windows App SDK.

First, do the following:

- **[Desktop apps only]** In the .wapproj file, if your **TargetPlatformMinVersion** is older than 10.0.17763.0, change it to 10.0.17763.0.
- The default project templates for both C++ and C# apps included the following lines. The `Application.Suspending` event is no longer called for desktop apps, so be sure to remove these lines (and any other uses of this event) if they are still present in your code:

  C#

  ```
  this.Suspending += OnSuspending;
  ```

  C++

  ```
  Suspending({ this, &App::OnSuspending });
  ```

Next, make these changes to your project:

1. In Visual Studio, go to **Tools** > **Nuget Package Manager** > **Package Manager Console**.

2. Enter the following commands:

```
Console

uninstall-package Microsoft.ProjectReunion -ProjectName {yourProject}
uninstall-package Microsoft.ProjectReunion.Foundation -ProjectName
{yourProject}
uninstall-package Microsoft.ProjectReunion.WinUI -ProjectName
{yourProject}
install-package Microsoft.ProjectReunion -Version 0.5.7 -ProjectName
{yourProjectName}
```

3. If you have a UWP app, your update process should be complete at this stage. If you have a desktop app, make the following changes in your Application (package).wapproj:

   a. Add this section:

```
XML

<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.5.7]">
        <IncludeAssets>build</IncludeAssets>
    </PackageReference>
</ItemGroup>
```

   b. Locate the `<TargetPlatformVersion>` tag, and add the following on a new line directly beneath that tag

```
XML

<AssetTargetFallback>net5.0-
windows$(TargetPlatformVersion);$(AssetTargetFallback)
</AssetTargetFallback>
```

   c. Remove this line:

```
XML

<AppxTargetsLocation
Condition="'$(AppxTargetsLocation)'==''">$(MSBuildThisFileDirectory)
build\</AppxTargetsLocation>
```

   And these lines:

```
XML
```

```
<Import Project="$(Microsoft_ProjectReunion_AppXReference_props)" />
<Import Project="$(Microsoft_WinUI_AppX_targets)" />
```

And this item group:

XML

```
<ItemGroup>
    <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.5.0-prerelease]" GeneratePathProperty="true">
      <ExcludeAssets>all</ExcludeAssets>
    </PackageReference>
    <PackageReference Include="Microsoft.ProjectReunion.WinUI"
Version="[0.5.0-prerelease]" GeneratePathProperty="true">
      <ExcludeAssets>all</ExcludeAssets>
    </PackageReference>
</ItemGroup>
```

Update from WinUI 3 Preview 4 to 0.5

If you created a desktop app using WinUI 3 Preview 4, you can follow these instructions to update your project to Project Reunion 0.5.

Before starting, make sure you have all the Windows App SDK prerequisites installed, including the latest VSIX and NuGet package. For more details, see Install tools for the Windows App SDK.

First, do the following:

- In the .wapproj file, if your TargetPlatformMinVersion is older than 10.0.17763.0, change it to 10.0.17763.0.
- The default project templates for both C++ and C# apps included the following lines. The `Application.Suspending` event is no longer called for desktop apps, so be sure to remove these lines (and any other uses of this event) if they are still present in your code:

  C#

  ```
  this.Suspending += OnSuspending;
  ```

  C++

```
Suspending({ this, &App::OnSuspending });
```

Next, make these changes to your project:

1. In Visual Studio, go to **Tools** > **Nuget Package Manager** > **Package Manager Console**.

2. Enter the following commands:

```
Console

uninstall-package Microsoft.WinUI -ProjectName {yourProject}
install-package Microsoft.ProjectReunion -Version 0.5.7 -ProjectName
{yourProjectName}
```

3. Make the following changes in your Application (package).wapproj:

   a. Add this section:

```
XML

<ItemGroup>
  <PackageReference Include="Microsoft.ProjectReunion" Version="
[0.5.7]">
    <IncludeAssets>build</IncludeAssets>
  </PackageReference>
</ItemGroup>
```

   b. Remove the following lines:

```
XML

<AppxTargetsLocation
Condition="'$(AppxTargetsLocation)'==''">$(MSBuildThisFileDirectory)
build\</AppxTargetsLocation>
```

```
XML

<Import Project="$(AppxTargetsLocation)Microsoft.WinUI.AppX.targets"
/>
```

4. Delete the existing `Microsoft.WinUI.AppX.targets` file under the {YourProject} (package)/build/ folder of your project.

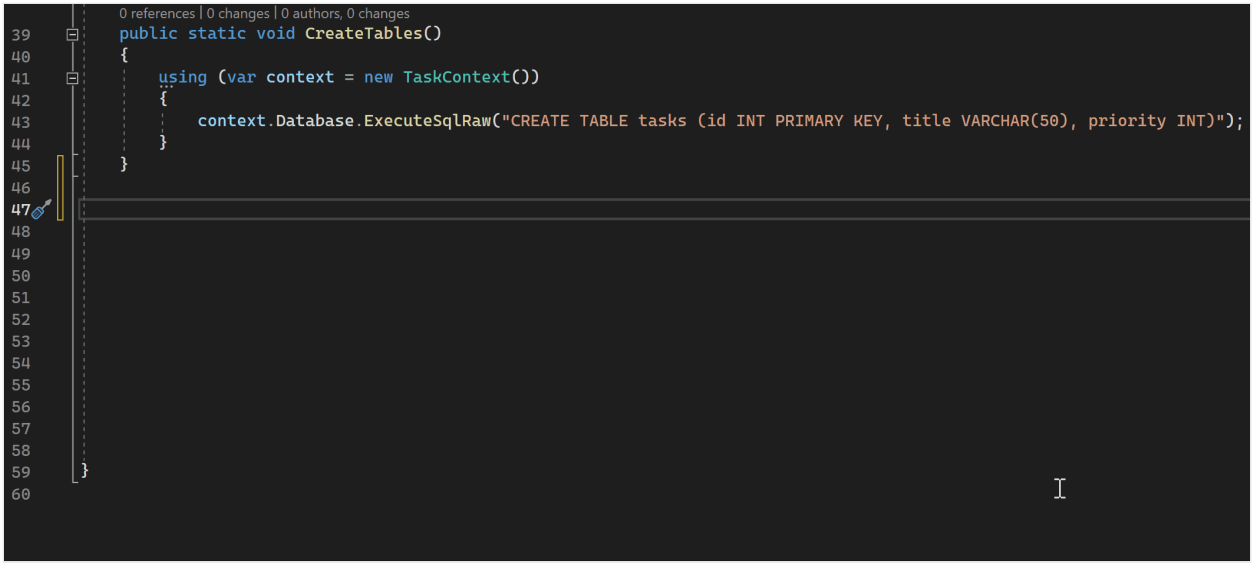
Use GitHub Copilot to create WinUI 3 / Windows App SDK apps in Visual Studio

Article • 11/27/2024

In this how-to, we'll demonstrate how GitHub Copilot can be used to build WinUI 3 / Windows App SDK desktop apps in Visual Studio. This guide builds upon *What is GitHub Copilot Completions for Visual Studio?*, offering tailored tips and best practices for Copilot-assisted WinUI 3 app development.



Prerequisites

- Visual Studio 2022 (v17.10+) with the Windows application development workload applied (see Get started with WinUI for additional configuration details). GitHub Copilot is included in Visual Studio 2022 v17.10 and later by default.
- An active subscription to GitHub Copilot associated with the GitHub account that you sign in to Visual Studio with.
- Familiarity with C#, WinUI, and Windows App SDK.

Use GitHub Copilot

Autocomplete your code snippets

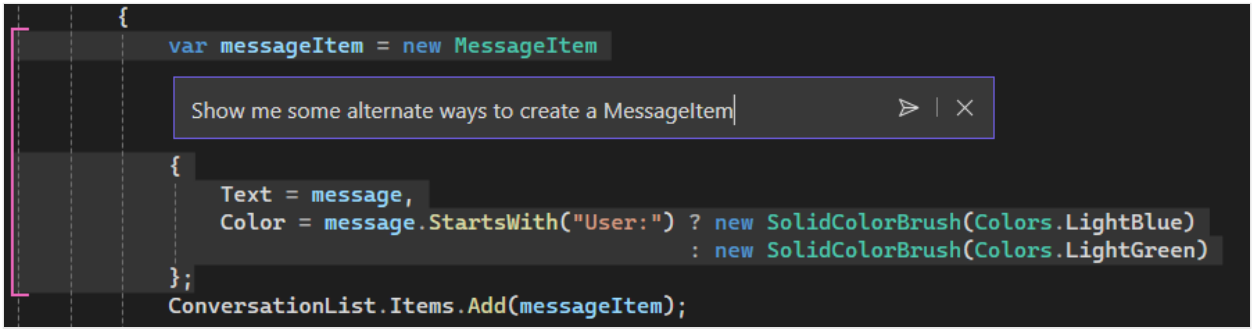
GitHub Copilot in Visual Studio provides real-time code suggestions and completions based on the code you write. The most straightforward way to use Copilot is to start typing code in the editor, and Copilot will try to autocomplete your code snippet. You can then accept or dismiss the suggestions:

```
<ItemsControl x:Name="ConversationList" Width="300">
    <ItemsControl.ItemTemplate>
        <DataTemplate>
            <Image x:Name="AvatarImage" Source="{Binding Avatar}" Width="50" Height="50" HorizontalAlignment="Left"/>
        </DataTemplate>
    </ItemsControl.ItemTemplate>
</ItemsControl>
```

> **Tip**
>
> If you don't see the GitHub Copilot suggestions, you can enable different aspects of the feature in Visual Studio's options under `Tools` -> `Options` -> `GitHub` -> `Copilot`.

Ask Copilot for suggestions

Right-click in the code editor and select `Ask Copilot`. A prompt window will open where you can chat inline with Copilot to get a list of suggestions based on the current cursor position and your prompt:



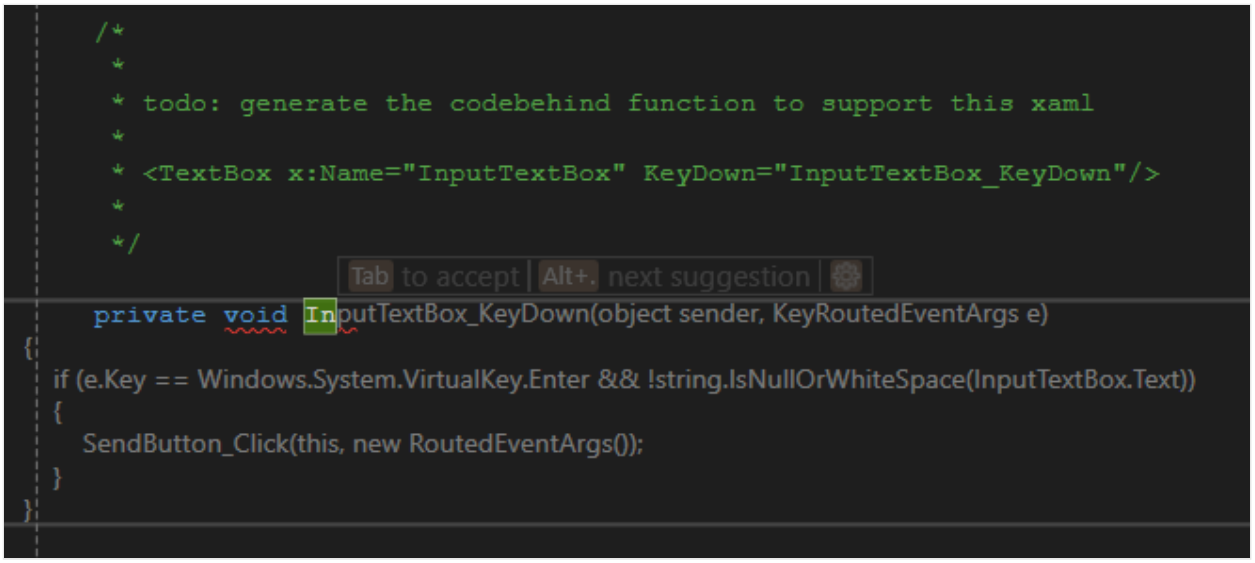
Prompt Copilot with plain-language comments

Although Copilot is used primarily for code completion, you can also use natural language comments to guide Copilot in generating specific code snippets. For example, you can use comments to request a specific feature or functionality:

```
<ItemsControl.ItemTemplate>
    <DataTemplate>
        <!-- we want an Image with max width of 200 -->
        <Image Source="{Binding}" MaxWidth="200"/>
    </DataTemplate>
</ItemsControl.ItemTemplate>
```

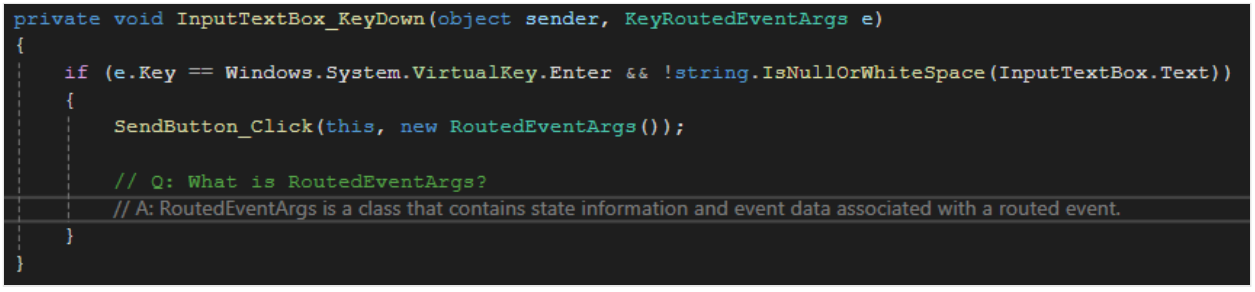
Use temporary comments to add code from other files to Copilot's context

If you're working on a code-behind file and want Copilot to incorporate context from the associated XAML file, you can use temporary comments to include this additional code within Copilot's context. Here's an example of how you can specify the XAML code first, and then have Copilot generate the corresponding C# code:



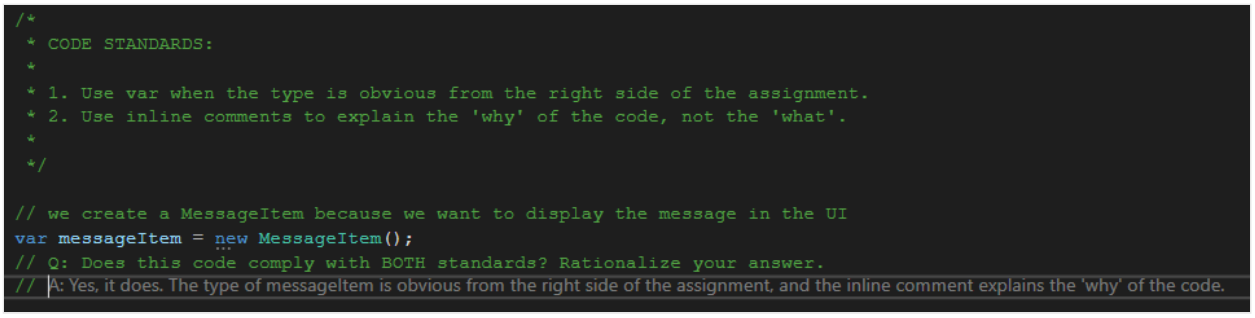
Ask Copilot to explain how something works with inline comments

You can use inline comments to ask Copilot to explain how a specific piece of code works. This is similar to using the inline Ask Copilot feature or the Copilot Chat window, except your prompt is typed directly into the code editor:



Use Copilot to test code standards

You can use Copilot to generate code that adheres to your project's coding standards, and to test any given snippet's adherence to those standards. Here's an example of how you can use inline comments to specify two conventions, and then have Copilot validate the code snippet against these conventions:



Recap

In this how-to, we demonstrated how to use GitHub Copilot in Visual Studio to assist you with WinUI 3 / Windows App SDK desktop app development. We covered how to:

- Autocomplete your code snippets.
- Generate autocomplete suggestions inline with Ask Copilot.
- Prompt Copilot with plain-language comments.
- Use temporary comments to add code from other files to Copilot's context.
- Ask Copilot to explain how something works with inline comments.
- Use Copilot to test and enforce code standards.

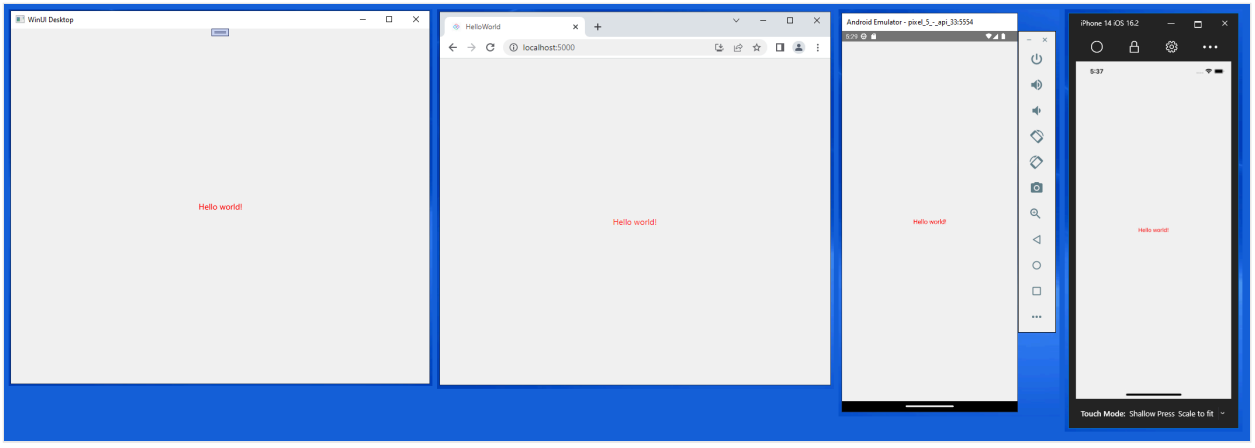
How to target multiple platforms with your WinUI 3 app

Article • 07/09/2024

Once you've created a starter Hello World WinUI 3 app, you might be wondering how to reach more users with a single codebase. This how-to will use Uno Platform to expand the reach of your existing application enabling reuse of the business logic and UI layer across native mobile, web, and desktop.



Prerequisites

- Visual Studio 2022 17.4 or later
- Set up your development computer (see Get started with WinUI)
- ASP.NET and web development workload (for WebAssembly development)
